The output of this command includes the following information:

Column	Description
BSSID	BSSID of the discovered radio of the AP.

Column	Description
ESSID	ESSID of the discovered radio of the AP or source BSSID through which the neighbor is discovered.
Channel	Channel of operation of the discovered radio of the AP.
phy-type (ArubaOS 8.9.0.0 or later versions)	Radio band of the AP. Displays one of the following values: <ul style="list-style-type: none"> ■ 2.4GHz ■ 5GHz ■ 6GHz (For Wi-Fi 6E APs)
SNR	Signal to noise ratio of the discovered radio of the AP.
Tx-power	Transmitter power of the discovered radio of the AP (if known).
PL (db)	Path loss to the discovered radio (using tx-power and SNR)
AP Flags	<ul style="list-style-type: none"> ■ Active: Discovered using Over-The-Air (OTA) updates ■ Passive: Discovered using passive scan ■ Indirect: Two hop neighbors discovered using neighbors OTA update
Last Update	Time stamp when last OTA update was received (total OTA updates)

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap arm rf-summary

```
show ap arm rf-summary {ap-name <ap-name>|{bssid <bssid>|{ip-addr <ip-addr>}  
[verbose]
```

Description

Show the state and statistics for all channels being monitored by an individual AP.

Parameter	Description
ap-name <ap-name>	Show channel data for an AP with a specific name.
bssid <bssid>	Show channel data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show channel data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.
verbose	(Optional) Include the channel quality history for all channels on the AP's radios in the output of this command.

Examples

The following example shows detailed information for the individual channels being monitored and statistics for each AP interface (For versions prior to ArubaOS 8.9.0.0). Use this command to verify an AP's RF health, or to determine why multiple APs in the same area are on the same channel.

```
(host)[node] #show ap arm rf-summary ap-name AP-205

The output of this command includes the following information:

Column	Description
phy-type (ArubaOS 8.9.0.0 or later versions)	The PHY type of the radio. Possible values are 2.4GHz , 5GHz , or 6GHz .
channel	Number of a radio channel used by the AP.
band	Displays the band, 2.4 GHz, 5 GHz, or 6 GHz.
retry	Number of 802.11 retry frames sent because a client failed to send an ACK.

Column	Description
phy-err	Number of PHY errors on the AP's current channel seen during the last second.
mac-err	Number of MAC errors on the AP's current channel seen during the last second.
noise	Current noise level, in -dBm.
util (Qual)	The quality of the channel based on the channel utilization.
cov-idx	The AP uses this metric to measure RF coverage. The coverage index is calculated as $x+y$, where "x" is the AP's weighted calculation of the Signal-to-Noise Ratio (SNR) on all valid APs on a specified 802.11 channel, and "y" is the weighted calculation of the Aruba APs SNR the neighboring APs see on that channel.
intf_idx	The AP uses this metric to measure co-channel and adjacent channel interference. The Interference Index is calculated as $a/b//c/d$, where: <ul style="list-style-type: none"> ■ Metric value "a" is the channel interference the AP sees on its selected channel. ■ Metric value "b" is the interference the AP sees on the adjacent channel. ■ Metric value "c" is the channel interference the AP's neighbors see on the selected channel. ■ Metric value "d" is the interference the AP's neighbors see on the adjacent channel. ■ To calculate the total Interference Index for a channel add "a+b+c+d".
Interface Name	Name of the gigabit Ethernet interface
Phy-Type (ArubaOS 8.9.0.0 or later versions)	The PHY type of the radio. Possible values are 2.4GHz , 5GHz , or 6GHz .
Current ARM Assignment	Current channels assigned by the AP's ARM profile.
Target Coverage Index	Ideal value of coverage index an AP tries to achieve on its channel.
Covered channels a/g	Number of channels that are currently being used by an AP's BSSIDs.
Free channels a/g	Number of channels that are available to an AP because that channel has a lower interference index.
ARM Edge State	If enabled, ARM-enabled APs on the network edge will not become Air Monitors.

Column	Description
<code>Last check channel/pwr</code>	Time elapsed since the AP checked its channel and power settings, in <i>hour:minute:second</i> format.
<code>Last change channel/pwr</code>	Time elapsed since the AP changed its channel and power settings, in <i>hour:minute:second</i> format.

<code>show ap arm client-match neighbors</code>	This command displays the BSSID of other APs seen by clients in the select AP's RF neighborhood.
<code>show ap arm virtual-beacon-report</code>	This command displays the virtual beacon report for an AP with a specific IP or MAC address.
<code>show ap arm client-match unsupported</code>	This command displays a list of clients that failed to be steered to a more optimal AP, and the reason the initial steering request was triggered.
<code>show ap arm client-match summary</code>	This command shows the history of AP association changes triggered by the client match feature.
<code>show ap arm client-match history</code>	This command shows the history of AP association changes triggered by the client match feature.

Command History

Release	Modification
ArubaOS 8.9.0.0	The <code>band</code> and <code>phy-type</code> parameters were introduced. The <code>band</code> is added at the end of the <code>Current ARM assignment</code> parameter.
ArubaOS 8.6.0.0	The output will display an interface report for Radio 2 for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

show ap arm scan-times

```
show ap arm scan-times {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

Description

Shows channel scan times for an individual AP and information on the channel being scanned.

Parameter	Description
ap-name <ap-name>	Show channel scan data for an AP with a specific name.
bssid <bssid>	Show channel scan data for a specific Basic Service Set Identifier (BSSID) on an AP.
ip-addr <ip-addr>	Show channel scan data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.

Examples

The output of this command shows scan times for every channel on AP-225. All UTB blocked channels are marked with the flag u in the scan channel table.

```
(host)[node]#show ap arm scan-times ap-name AP-225

The output of this command includes the following parameters:

Column	Description
channel	Displays the channels in the group.
band	Displays the band, 2.4 GHz, 5 GHz, or 6 GHz.
assign-time (ms)	The cumulative time spent on the channel.
scans-attempted	The number of times an AP attempted to scan a channel.
scans-rejected	The number of times an AP attempted to scan a channel, but was unable to scan because the scan was halted by the power save, VoIP aware, video aware or load aware ARM features.
scans-deferred	The number of times an AP deferred to scan a channel due to an event such as a radar detection.
dos-scans	The number of times an AP visited the channel to contain a rogue device.
flags	Displays additional information about the channel. The flags key is displayed at the bottom of the Channel Scan Time table.
group_width	The channel width of the group.
timer-tick	The timer-tick of the last scan.
UTB filter results	
Band selected	Displays the band selected in the regulatory-profile, used by the AP that is queried. If the band selected is 5 GHz, the First blocked channel is displayed. If the band selected is 6 GHz, the Last blocked channel is selected.
First blocked channel	Displays the first channel blocked in the 5 GHz band. All the channels from this channel to the last channel of the 5 GHz band will be blocked.

Column	Description
Last blocked channel	Displays the last channel that is blocked in the 6 GHz band. All the channels from the start of the 6 GHz band until this channel will be blocked.

show ap arm split-scan-history

```
show ap arm split-scan-history {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

Description

Show scanning information for a "split-scan", where ARM performs an additional scans on each channel within a 40 MHz channel pair or 80 MHz channel set.

If ARM reports a high noise floor on a channel within a 40 MHz channel pair or 80 MHz channel set, ARM performs an additional 20 MHz scan on each channel within that channel pair or set, to determine the actual noise floor of each affected channel. This allows ARM to avoid assigning the overutilized channel, while still allowing channel assignments to the other unaffected channels in that channel pair or set.

Parameter	Description
ap-name <ap-name>	Show scan data for an AP with a specific name.
bssid <bssid>	Show scan data for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show scan data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.

Examples

The output of this command shows information about one split-scan performed on channel 161E.

```
(host)[node]# show ap arm split-scan-history ap-name 1242-ac
Interface :wifi0
Split Scan History
-----
Time of setup           Channel scan   Number of Split scans   Noise Floor
-----
2013-10-08 03:11:40   161E          4                        69
Interface :wifi1
```

The output of this command includes the following parameters:

Column	Description
Time of setup	Timestamp showing the date and time the scan was performed

Column	Description
Channel Scan	The channel pair or channel set scanned
Number of Split Scans	The number of times ARM performed an additional split scan.
Noise Floor	Noise floor recorded on the primary channel within that channel pair or channel set.

show ap arm state

```
show ap arm state [ap-name <ap-name>|dot11a|dot11g|ip-addr <ip-addr>]
```

Description

Displays Adaptive Radio Management (ARM) information for an individual AP's neighbors, or show all available data for any neighboring AP using an 802.11a or 802.11g radio type. Include an AP name or IP address to show data for just a single AP, or use the **dot11a** or **dot11g** keywords to show data for all APs using that radio type.

Parameter	Description
ap-name <ap-name>	Show aggregate ARM Neighbor Information for a specific AP.
dot11a	Show aggregate ARM Neighbor Information for all APs using an 802.11a radio.
dot11g	Show aggregate ARM Neighbor Information for all APs using an 802.11g radio.
ip-addr <ip-addr>	Show aggregate ARM Neighbor Information for a AP with a specific IP address by entering its IP address in dotted-decimal format.

Examples

The output of this command shows 802.11a information for all neighboring APs.

```
(host)[node]# show ap arm state

show ap arm state ap-name AP49
AP-1249:10.100.139.233:52:21:26-Edge:disable : Client Density:13
Neighbor Data
-----
Name                IP Address SNR  Assignment  Neighbor Density
-----
AP42                10.100.139.249  41   52/21      13/17/100/76
AP09                10.100.139.224  22   56/21      3/5/23/60
AP48                10.100.139.241  36   60/21      9/11/69/81
```

The output of this command includes the following information:

Column	Description
Name	Name of an AP.

Column	Description
IP address	IP address of an AP.
SNR	Signal-to-noise (SNR) ratio. SNR is the power ratio between an information signal and the level of background noise.
Path loss	Path loss to the discovered radio (using tx-power and SNR)
Channel/Pwr	The AP's current channel assignment.
Neighbor Density	The neighborhood density for the specified AP is listed with the values A/B/C/D, where: <ul style="list-style-type: none"> ■ A= Number of the AP's clients heard in the AP neighbor's client list ■ B= Number of clients in AP neighbor's client list ■ C= Density percentage, (AP clients heard in in the AP neighbor client list / AP client density * 100). ■ D= Density Percentage (AP clients heard in the AP neighbor's client list / neighbor client density * 100)

show ap arm status

```
show ap arm status {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

Description

Run this command under the supervision of Aruba support to display detailed debugging Adaptive Radio Management (ARM) information and ARM status counters for an individual AP.

Parameter	Description
ap-name <ap-name>	Show ARM status for an AP with a specific name.
bssid <bssid>	Show ARM status for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show ARM status for an AP with a specific IP address. Enter the IP address in dotted-decimal format.

Example

The output of this command shows detailed debugging Adaptive Radio Management (ARM) information and ARM status counters for an individual AP:

  ip-addr <ipaddr>
  ip6-addr <ip6-addr>
  phy-type 80211a|80211b|80211g
```

Description

If the client match feature is enabled, the output of this command displays the virtual beacon report for an AP with a specific IP or MAC address. The managed device sends APs a list of clients that should not be allowed to associate to that AP.

Parameter	Description
ap-name <name>	Name of an AP for which you want to view a virtual beacon report.
ip-addr <ipaddr>	IPv4 address of an AP for which you want to view a virtual beacon report.
ip6-addr <ip6addr>	IPv6 address of an AP for which you want to view a virtual beacon report.
phy-type	Display virtual beacon report data for an AP radio with one of the following phy types: <ul style="list-style-type: none">■ 80211a■ 80211b■ 80211g

Example

```
(host)[node] #show ap arm virtual-beacon-report ap-name 1263-ac
```

```
Interface:wifi0
Rx VBR Reports:683

9c:1c:12:fe:13:40 1       -68      12

```

The output of this command includes the following parameters:

Column	Description
AP	MAC address of the AP from which the client can detect a signal
Channel	Channel on which the signal was detected
Signal	Signal strength, in dBm, of the probe request received from Client
EIRP	Amount of power transmitted from the AP antennae
Assoc	A "Y" in this field indicates that the client is currently associated to that AP radio

    essid <essid>
  voip-only
```

Description

This command shows the AP association table. Use this command to check if user is connected to an AP. This command validates whether the client is associated and indicates the last AP to which it was connected. If the flags column shows an 'A', the client is currently associated with that AP. Alternately, if the client is not currently associated, the AP with the smallest value of association time is the last AP used by the client.

Parameter	Description
anyspot	Shows AP associations for anyspot virtual AP.
ap-group <ap-group>	Shows AP associations for the specified AP group.
ap-name <ap-name>	Shows AP associations for the specified AP name.
bssid <bssid>	Shows AP associations for the specified Basic Service Set Identifier (BSSID). The BSSID is usually the MAC address of an AP.

Parameter	Description
channel <channel>	Shows AP associations for the specified channel.
client-mac <client-mac>	Shows AP associations for the specified MAC address of a client.
dormant	Shows AP associations for the specified dormant station.
ssid <ssid>	Shows AP associations for the specified Extended Service Set Identifier (ESSID). An ESSID is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, enclose the ESSID in quotation marks.
ip-addr <ip-addr>	Shows AP associations for the specified IP address of an AP.
ip6-addr <ip-addr>	Shows AP association for the specified IPv6 address of an AP.
phy	(For versions prior to ArubaOS 8.9.0.0)Shows AP association for the specified PHY radio type (802.11a, 802.11b or 802.11g) Use the corresponding keywords a , b , or g . (For ArubaOS 8.9.0.0 or later versions)Shows AP association for the specified PHY radio type (2.4 GHz, 5 GHz, or 6 GHz) Use the corresponding keywords 2 , 5 , or 6 .
remote	Shows AP association for bridge mode AP.
voip-only	Shows AP association for VoIP-only clients.

Example

The following example shows the AP association table based on MAC address of the client (For versions prior to ArubaOS 8.9.0.0).

```

show ap authorization-profile

```
show ap authorization-profile [<profile-name>]
```

Description

This command shows information about AP authorization profiles. The AP authorization profile specifies which configuration should be assigned to a remote AP that has been provisioned but not yet authenticated at the remote site.

By default, these yet-unauthorized APs are put into the temporary AP group **authorization-group** and assigned the predefined profile **NoAuthApGroup**. This configuration allows the user to connect to an unauthorized remote AP via a wired port then enter a corporate username and password. Once a valid user has authorized the AP and the remote AP will be marked as authorized on the network. The remote AP will then download the configuration assigned to that AP by its permanent AP group.

Run this command without the **<profile-name>** option to display the entire AP authorization profile list, including profile status and the number of references to each profile. Include a profile name to display the authorization group defined for that profile.

Parameter	Description
<profile-name>	The name of an existing AP authorization profile.

Examples

The following example lists all AP authorization profiles. The **References** column lists the number of other profiles with references to that authorization profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined AP authorization profiles will not have an entry in the **Profile Status** column.

```
(host) #show ap authorization-profile

AP Authorization profile List
-----
Name           References  Profile Status
----           -
Noauthprofile  1
default        2           Predefined (editable)
Total:2
To display the authentication group for an individual profile, include the
<profile> parameter. The example below shows the profile details for the AP
authorization profile Default.
(host) #show ap authorization-profile default

AP Authorization profile "default" (Predefined (editable))
-----
```

```

Parameter          Value
-----
AP authorization group NoAuthApGroup

```

The output of the **show ap authorization** command includes the following parameters:

Column	Description
AP authorization group	Name of a configuration profile to be assigned to the group unauthorized remote APs.

Related Commands

Command	Description
ap authorization-profile	This command defines a temporary configuration profile for remote APs that are not yet authorized on the network.

show ap blacklist-clients / show ap denylist-clients

show ap blacklist-clients / show ap denylist-clients

Description

Show a list of clients that have been denied access.

Use the [stm](#) CLI command to add or remove users from a denylist. Additionally, the **dot1x authentication**, **VPN authentication** and **MAC authentication** profiles allow you to automatically denylist a client if machine authentication fails.

Examples

The output of this command shows that the controller has a single user-defined blocked client.

```
(host)# show ap blacklist-clients/show ap denylist-clients
```

```
Blacklisted/Denylisted Clients
-----
STA          reason          block-time(sec)  remaining time(sec)
---          -
00:1E:37:CB:D4:52  user-defined  45              3555
```

```
(host)# show ap denylist-clients
Denylist Protected
-----
STA  remaining time(sec)
---  -----
```

The output of this command includes the following information:

Column	Description
STA	MAC address of the blacklisted/denylisted client.
reason	The reason that the user was blacklisted. <ul style="list-style-type: none">■ ARP-attack: Blacklisted/Denylisted for an ARP attack.■ user-defined: Blacklisted/Denylisted due to blacklist criteria were defined by the network administrator■ mitm-attack: Blacklisted/Denylisted for a man in the middle (MITM) attack; impersonating a valid enterprise AP.■ gratuitous-ARP-attack: Blacklisted/Denylisted for a gratuitous ARP attack.■ ping-flood: Blacklisted/Denylisted for a ping flood attack.■ session-flood: Blacklisted/Denylisted for a session

Column	Description
	flood attack. <ul style="list-style-type: none"> ■ syn-flood: Blacklisted /Denylisted for a syn flood attack. ■ session-blacklist/denylist: User session was blacklisted/denylisted . ■ IP spoofing: Blacklisted/Denylisted for sending messages using the IP address of a trusted client. ■ ESI-blacklist/denylist: An external virus detection or intrusion detection application or appliance blacklisted/denylisted the client. ■ CP-flood: Blacklisting/Denylisting for flooding with fake AP beacons. ■ UNKNOWN: Blacklist/Denylisting reason unknown.
block-time (sec)	Amount of time the client has been blocked, in seconds.
remaining time(sec)	Amount of time remaining before the client will be allowed access to the network again.

show ap blacklist-protected / show ap denylist-protected

show ap blacklist-protected / show ap denylist-protected

Description

Show a list of iOS clients that have received a deauth message from the ARM traffic steering feature.

iOS mobile devices such as an iPhone, iPad, or iPod automatically block an SSID if that device receives more than two deauthentication messages within a five-minute period. To protect iOS devices from blacklisting/denylisting an SSID due to repeated traffic steering attempts, ArubaOS limits the number of traffic steering attempts for these devices to no more than one steering attempt every five minutes. Issue the `show ap blacklist-protected / show ap denylist-protected` command to view a list of clients that are protected against further deauthentication actions for a period of time.

This command is used to display the devices that were in the time period where they would be protected against additional blacklistings/denylistings because of the rate limit setting in.

Examples

The output of this command shows that the controller has a single user-defined blocked client.

```
(host) #show ap blacklist-protected
Blacklist Protected
-----
STA                remaining time(sec)
---                -
b4:18:d1:5f:a5:d2  291
```

Starting from ArubaOS 8.9.0.0, the output of the command is displayed as follows:

```
(host) #show ap denylist-protected
Denylist Protected
-----
STA                remaining time(sec)
---                -
b4:18:d1:5f:a5:d2  291
```

The output of this command includes the following information:

Column	Description
STA	MAC address of the blocked client.
remaining time	The amount of time that the client will remain blocked.

Related Commands

show ap ble-database

show ap ble-database [long]

Description

This command is used to display AP Beacon (APB) information collected by BLE relay. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
long	This optional parameter is used to display the following additional information, <ul style="list-style-type: none">■ Bank A UI Sta■ Bank B UI Sta

Example

The following command displays AP Beacon (APB) information collected by BLE relay,

```
(host) #show ap ble-database
BLE APB Information
-----
AP Name  AP Group  BLE MAC  BLE Cur. Bank  BLE Opp. Bank  AP Eth MAC  AP IP
Reported at  ConfigID  Status
-----
-----
Total AP BLE devices reported:0
Note:'Status' column indicates whether information received for an AP's
radio is 'Current' (message received in the last 10 minutes)
: or 'OutOfDate' (message received more than last 10 minutes ago and/or AP
might be down).
```

    ap-name <ap-name>
    bssid <bssid>
    details
    ip-addr <ip-addr>
    ip6-addr <ip6-addr>
    port <slot/port>
```

Description

This command shows the Basic Service Set (BSS) table of an AP. To filter this information and view BSS table data for an individual AP or a specific port and slot number, include the **ap-name**, **bssid**, **essid**, **ip-addr**, or **port** keywords.

Parameter	Description
ap-name <ap-name>	Shows the BSS table for the specified AP name.
bssid <bssid>	Shows the BSS table for the specified Basic Service Set Identifier (BSSID) of an AP. The BSSID is usually the MAC address of an AP.
counters	Shows the BSS table of counters for the specified AP.
details	Shows the BSS table with detailed columns.
essid <essid>	Show the BSS table for the specified Extended Service Set Identifier (ESSID) of an AP. An ESSID is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, enclose the ESSID in quotation marks.
ip-addr <ip-addr>	Shows the BSS table for the specified IP address of an AP.

Parameter	Description
ip6-addr <ip6-addr>	Shows the BSS table for the specified IPv6 address of an AP.
port <slot/port>	Shows the BSS table for the specified port of an AP.
standby	Show the BSS table for the specified AP in standby mode.

Example

The following example shows the BSS table for the active APs.

- For versions prior to ArubaOS 8.9.0.0:

```
(host) [mynode] #show ap bss-table

The output of this command includes the following information:

Column	Description
bss	The AP Basic Service Set Identifier (BSSID). This is usually the MAC address of the AP
ess	The AP Extended Service Set Identifier (ESSID).
port	The slot and port used by the controller, in the format <slot>/<module>/<port>.
ip	IP address of an AP.
phy (For versions prior to ArubaOS 8.9.0.0)	An AP radio type. Possible values are: <ul style="list-style-type: none"> ■ a—802.11a ■ a-HT—802.11a high throughput ■ g— 802.11g ■ g-HT—802.11g high throughput
band/ht-mode/bandwidth (ArubaOS 8.9.0.0 or later versions)	The AP radio type displayed by radio band/throughput type/channel bandwidth. Possible values for each type are as follows: <ul style="list-style-type: none"> ■ band—2.4GHz, 5GHz, or 6GHz ■ ht-mode—HT, VHT, or HE ■ bandwidth—20MHz, 40MHz, 80MHz, 80+80MHz, or 160MHz
ch/EIRP/max-EIRP	Radio channel used by the AP/current effective Isotropic Radiated Power (EIRP) /maximum EIRP.

Column	Description
type	Shows whether the AP is working as an access point (AP) or air monitor (AM).
cur-cl	Current number of clients on the AP.
ap name	Name of the AP.
in-t (s)	Number of seconds that an AP has been inactive.
tot-t	An AP's total active time, in seconds.
mtu	MTU size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.
acl-state	<p>An ACL can enable or disable an AP during specific time ranges.</p> <ul style="list-style-type: none"> ▪ Disabled: An ACL with time restrictions is currently disabled (so the AP is enabled). ▪ Enabled: An ACL with time restrictions is currently enabled (so the AP is disabled). ▪ This data column will display a dash (-) if no ACLs are currently configured for the AP.
acl	The ACL ID is displayed based on the role set.
fm	<p>Listed below are the forwarding modes available:</p> <ul style="list-style-type: none"> ▪ T-Tunnel ▪ S-Split ▪ D-Decrypt Tunnel ▪ B-Bridge (s-standard, p-persistent, b-backup, a-always) <p>NOTE: If anyspot is enabled for a particular BSSID, then it is represented as n in the Forwarding Mode parameter.</p>
flags	The type of flags available for the AP.
cluster	The cluster name for the AP.
datazone	The name of the datazone.

show ap bw-report

```
show ap bw-report {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

Description

Show the bandwidth reporting table for a specific AP.

Parameter	Description
ap-name <ap-name>	Show bandwidth data for an AP with a specific name.
bssid <bssid>	Show bandwidth data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.
ip-addr <ip-addr>	Show bandwidth data for an AP with a specific IP address by entering an IP address in dotted-decimal format.

Examples

The output of the following command shows the Aruba AP bandwidth table for an AP with the IP address 192.0.2.170.

```
show ap bw-report ap-name AP555-0
```

```
Bandwidth report for AP "AP555-0" radio 0
```

```
-----  
Virtual AP  Allocated Share  Actual Share  Offered Load  Delivered Load  
-----  
corp1344-guest      0%      0%      0 kbps  0 kbps  
corp1344-ethersphere-wpa2 0%      0%      0 kbps  0 kbps  
Average Throughput:0 kbps
```

```
Bandwidth report for AP "AP555-0" radio 1
```

```
-----  
Virtual AP  Allocated Share  Actual Share  Offered Load  Delivered Load  
-----  
corp1344-guest      0%      0%      0 kbps  0 kbps  
corp1344-ethersphere-voip 0%      0%      0 kbps  0 kbps  
corp1344-ethersphere-vocera 0%      0%      0 kbps  0 kbps
```

```
Bandwidth report for AP "AP555-0" radio 2
```

```
-----  
Virtual AP  Allocated Share  Actual Share  Offered Load  Delivered Load  
-----
```

```
Average Throughput:0 kbps
```

The output of this command includes the following information for all radios on the AP:

Column	Description
Virtual AP	Name of a Virtual AP
Allocated Share	Maximum percentage of total bandwidth available to that Virtual AP.
Actual Share	Actual percentage of total bandwidth used by a Virtual AP.
Offered Load	Attempted throughput for the Virtual AP, in kbps.
Delivered Load	Actual throughput for the Virtual AP, in kbps. This value may be less than the offered load if the Virtual AP has used all its allocated bandwidth.
Average Throughput	Average throughput for the virtual AP, in kbps.

show ap cellular bearer

```
ap-name <ap-name>
ip-addr <ip-addr>
ip6-addr <ip6-addr>
```

Description

Displays the cellular bearer information of the AP.

Parameter	Description
ap-name <ap-name>	Displays the dual access point name (APN) details configured on the SIM of an Aruba USB LTE modem.
ip-addr <ip-addr>	Displays the filter on the IP address.
ip6-addr <ip6-addr>	Displays the IPv6 address of the access point.

Example

An example output of the `show ap cellular bearer ap-name` command.

```
(host) [mynode] #show ap cellular bearer ap-name 20:4c:03:0a:12:fc

Parameter	Description
ap-name <name>	Shows data for an AP with a specific name.
ip-addr <ipaddr>	Shows data for an AP with a specific IPv4 address.
ip6-addr <ip6-addr>	Shows data for an AP with a specific IPv6 address.

Example

The following example shows the SIM card information for an Aruba USB modem connected to an AP.

```
(host) [mynode] (config) #show ap cellular sim ap-name 20:4c:03:a4:a6:85
SIM card information

All platforms	Base operating system.	Enable or Config mode on Mobility Master.

show ap cellular stats

```
show ap cellular stats
```

Description

This command shows statistics on the transmitted and received data bytes of a USB modem.

Parameter	Description
ap-name <name>	Shows data for an AP with a specific name.
ip-addr <ipaddr>	Shows data for an AP with a specific IPv4 address.
ip6-addr <ip6-addr>	Shows data for an AP with a specific IPv6 address.

Example

The following example shows the statistics of data bytes for an Aruba USB modem connected to an AP.

```
(host) [mynode] (config) #show ap cellular stats ap-name 20:4c:03:a4:a6:85
Cellular statistics

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap client trail-info

```
show ap client trail-info [<client-mac>]
```

Description

Use this command to show client activity for debugging purposes. This information includes client activity history and roaming, including reasons for client deauthentication, and any alerts or errors encountered by that client. Without arguments, the table gives the last entry for a number of clients - limited by buffer space. Include the optional `<client-mac>` parameter to show additional details for that specific client.

Client-trail information may be available for clients that are no longer active, as the controller saves a limited amount of client data in a buffer. The maximum number of clients for which trail information is saved is determined by is determined by the controller platform. Each controller saves client trail information for twice the number of active clients supported by that controller platform.

Parameter	Description
<code><client-mac></code>	MAC address of the client.

Examples

The following example shows client-trail information for all clients associated with the controller.

```
(host) #show ap client trail-info

Client Trail Info
-----
MAC          BSSID          ESSID  AP-name  VLAN  Deauth-
reason      Alert

```

The output of these commands include the following information:

Column	Description
MAC	MAC address of the client
BSSID	BSSID of the client
ESSID	ESSID to which the client associated
AP-name	Name of the AP to which the client associated
VLAN	VLAN ID of the VLAN to which the client associated.
Death-reason	Reason why the client was deauthorized.
Alert	Reason why alerts were triggered by the client
Timestamp	If you include the optional <client-mac> parameter, the output will include a timestamp that indicates the time each alert or deauthorization was triggered.
Mobility-Trail	If you include the optional <client-mac> parameter, the output will include the AP name, BSSID and ESSID of the APs to which the client connected, as well as a timestamp showing when the connections were initiated.

show ap client status

show ap client status <client-mac>

Description

Shows the current status of a specific client.

Parameter	Description
<client-mac>	MAC address of a client

Examples

The output of the command shows the status of an individual client in the STA (station) table.

```
(host) #show ap client status 00:13:fd:42:32:38

STA Table
-----
bssid          auth  assoc  aid  l-int  essid      vlan-id  tunnel-id
-----
00:1a:1e:a3:02:c9  y    y      7   10    corp-wpa2  65      0x10c0
State Hash Table
-----
bssid          state      reason
-----
00:1a:1e:a3:02:c9  auth-assoc  0
```

The output of this command includes the following information:

Column	Description
bssid	Basic Service Set ID (BSSID) of the client.
auth	This column displays a y if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an n .
assoc	This column displays a y if the AP has been configured for 802.11 association frame types. Otherwise, it displays an n .
aid	Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second.

Column	Description
l-int	Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second.
essid	Extended Service Set ID (ESSID) of the client.
vlan-id	VLAN ID of the VLAN used by the client.
tunnel-id	Identification number for the tunnel.
state	If the client has been both authorized and associated, this data column will display auth-assoc . If the client has only been authorized, this data column will display auth .
Reason	If the client failed to authenticate, this data column lists the reason code for 802.11 authentication failure.

show ap config

```
show ap config {ap-group <ap-group>}|{ap-name <ap-name>}|{ssid <ssid>}
```

Description

Show a large list of configuration settings for an ap-group or an individual AP.

Parameter	Description
ap-group <ap-group>	Display configuration settings for an AP group.
ap-name <ap-name>	Display configuration settings for an AP with a specific name.
ssid <ssid>	Display configuration settings for an AP with a specific ESSID. An ESSID is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks.

Examples

The following example shows just some of the configuration settings displayed in the output of this command (For versions prior to ArubaOS 8.9.0.0).

```

The output of this command includes the following parameters.

Column	Description
LMS IP	The IPv4 address of the LMS - the Aruba managed device which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network.
LMS IPv6	The IPv6 address of the LMS - the Aruba managed device which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network.
Backup LMS IP	For networks with multiple managed devices, this parameter displays the IPv4 address of a backup to the IP address specified with the lms-ip parameter.

Column	Description
Backup LMS IP	For networks with multiple managed devices, this parameter displays the IPv6 address of a backup to the IP address specified with the lms-ip parameter.
LMS Preemption	When this parameter is enabled, the LMS automatically reverts to the primary LMS IP address when it becomes available.
LMS Hold-down Period	Time, in seconds, that the primary LMS must be available before an AP returns to that LMS after failover.
Number of IPsec retries	Shows the number of times the AP will attempt to recreate an IPsec tunnel with Mobility Conductor before the AP will reboot. The supported range is 0-1000 retries, and the default value is 360. A value of 0 disables the reboot.
LED operation mode	The operating mode for the LEDs (11n APs only) <ul style="list-style-type: none"> ■ normal: Normal mode ■ off: All LEDs off
Master/Conductor controller IP address	For networks with multiple managed devices, this parameter displays the IP address of Mobility Conductor.
RF Band	For dual-band radios, this parameter displays the RF band in which the AP should operate: <ul style="list-style-type: none"> ■ g = 2.4 GHz ■ a = 5 GHz
Double Encrypt	This parameter applies only to remote APs. Double encryption is used for traffic to and from a wireless client that is connected to a tunneled SSID. When enabled, all traffic is re-encrypted in the IPsec tunnel. When disabled, the wireless frame is only encapsulated inside the IPsec tunnel.
Native VLAN ID	Native VLAN for bridge mode virtual APs (frames on the native VLAN are not tagged with 802.1q tags).

Column	Description
SAP MTU	MTU size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.
Bootstrap threshold	Number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots. On the managed device, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.
Request Retry Interval	Interval, in seconds, between the first and second retries of AP-generated requests. If the configured interval is less than 30 seconds, the interval for subsequent retries is increased up to 30 seconds.
Maximum Request Retries	Maximum number of times to retry AP-generated requests, including keepalive messages. After the maximum number of retries, the AP either reboots or tries the IP address specified by the backup LMS IP address (if configured).
Keepalive Interval	Time, in seconds, between keepalive messages from the AP
Dump Server	(For debugging purposes.) Displays the server to receive the core dump generated if an AP process crashes.
Telnet	Reports whether telnet access the AP is enabled or disabled.
SNMP sysContact	SNMP system contact information.
AeroScout RTLS Server	Displays whether or not the AP will send RFID tag information to an AeroScout RTLS server.
RTLS Server configuration	Displays whether or not the AP will send RFID tag information to an RTLS server.
Remote-AP DHCP Server VLAN	Shows the VLAN ID of the remote-AP DHCP server used when the managed device is unreachable.

Column	Description
Remote-AP DHCP Server Id	Shows the IP Address of the DHCP DNS Server.
Remote-AP DHCP Default Router	Shows the IP Address of the DHCP Default Router.
Remote-AP DHCP Pool Start	Shows the IP Address used as start of DHCP Pool.
Remote-AP DHCP Pool End	Shows the IP Address used as end of DHCP Pool.
Remote-AP DHCP Pool Netmask	Shows the netmask of DHCP Pool.
Remote-AP DHCP Lease Time	Shows the length of leases, in days (0 means infinite).
Remote-AP uplink total bandwidth	This is the total reserved uplink bandwidth (in Kilobits per second)
Remote-AP bw reservation	Session ACLs with uplink bandwidth reservation in kilobits per second. You can specify up to three session ACLs to reserve uplink bandwidth.
Heartbeat DSCP	DSCP value of AP heartbeats (0-63).
Session ACL	Shows the ACL applied on the uplink of a remote AP.
Maintenance Mode	Shows if Maintenance mode is enabled or disabled. If enabled, APs stop flooding unnecessary traps and syslog messages to NMS systems or network operations centers when deploying, maintaining, or upgrading the network. The managed device still generates debug syslog messages if debug logging is enabled.
Remote-AP Local Network Access	Enable or disable local network access across VLANs in a Remote-AP.
Radio enable	Shows if the AP's radio is enabled or disabled.
Mode	Shows the operating modes for the AP. <ul style="list-style-type: none"> ■ ap-mode: Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN. ■ am-mode: Device behaves as an

Column	Description
	<p>AM to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.</p> <ul style="list-style-type: none"> ■ spectrum-mode: Device behaves as a spectrum monitor, sending spectrum analysis data to the managed device. Spectrum monitors do not serve clients.
High throughput enable (radio)	Shows if high-throughput (802.11n) features on the 2.4 GHz frequency band are enabled or disabled.
Channel	Shows the channel number for the AP's 802.11a or 802.11n physical layer.
Beacon Period	Shows the time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.
Beacon Regulate	Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air.
Transmit EIRP	Shows the current transmission power level.
Advertise 802.11d and 802.11h Capabilities	This column reports whether or not the AP will advertise its 802.11d (Country Information) and 802.11h (TPC) capabilities.
TPC Power	The transmit power advertised in the TPC IE of beacons and probe responses. Range: 0-51 dBm
Spectrum Load Balancing	The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the managed device is responding to the wireless clients' probe requests.

Column	Description
	<p>If enabled, the managed device compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p>
<p>Spectrum Load Balancing mode</p>	<p>Spectrum Load Balancing Mode allows control over how to balance clients. Select one of the following options:</p> <ul style="list-style-type: none"> ■ channel: Channel-based load-balancing balances clients across channels. This is the default load-balancing mode ■ radio: Radio-based load-balancing balances clients across APs
<p>Spectrum load balancing update interval</p>	<p>This value determines how often spectrum load balancing calculations are made (in seconds). The default value is 30 seconds.</p>
<p>Advertised regulatory max EIRP</p>	<p>A cap for an radio's maximum EIRP. Even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.</p>
<p>Spectrum load balancing domain</p>	<p>Define a spectrum load balancing domain to manually create RF neighborhoods.</p> <p>This option creates RF neighborhood information for networks that have disabled ARM scanning and channel assignment.</p> <ul style="list-style-type: none"> ■ If spectrum load balancing is enabled in a 802.11a radio profile but the spectrum load balancing domain is <i>not</i> defined, ArubaOS uses ARM to calculate RF neighborhoods. ■ If spectrum load balancing is enabled in a 802.11a radio profile and a spectrum load balancing domain <i>is/also</i> defined, AP radios belonging to the same spectrum

Column	Description
	<p>load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by ARM.</p>
<p>Rx sensitivity tuning based channel reuse</p>	<p>The channel reuse feature can operate in either of the following three modes; static, dynamic or disable. (This feature is disabled by default.)</p> <ul style="list-style-type: none"> ■ Static mode: This mode of operation is a coverage-based adaptation of the CCA thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa. ■ Dynamic mode: In this mode, the CCA thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client. ■ Disable mode: This mode does not support the tuning of the CCA Detect Threshold.
<p>Rx sensitivity threshold</p>	<p>RX Sensitivity Tuning Based Channel Reuse Threshold, in -dBm. If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (in -dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength. If the value is set to zero, the feature will automatically determine an appropriate threshold</p>
<p>Non 802.11a interference Immunity</p>	<p>The value for 802.11 Interference Immunity. This parameter sets the interference immunity on the 2.4 GHz band.</p>

Column	Description
	<p>The default setting for this parameter is level 2. When performance drops due to interference from non-802.11 interferes (such as DECT or Bluetooth devices), the level can be increased up to level 5 for improved performance. However, increasing the level makes the AP slightly “deaf” to its surroundings, causing the AP to lose a small amount of range.</p> <p>The levels for this parameter are:</p> <ul style="list-style-type: none"> ■ Level-0: no ANI adaptation. ■ Level-1: noise immunity only. ■ Level-2: noise and spur immunity. This is the default setting ■ Level-3: level 2 and weak OFDM immunity. ■ Level-4: level 3 and FIR immunity. ■ Level-5: disable PHY reporting.
Enable CSA	Displays whether or not the AP has enabled CSAs for 802.11h.
CSA Count	Number of channel switch announcements that must be sent before the AP will switch to a new channel.
Management Frame Throttle interval	Average interval that rate limiting management frames are sent from this radio, in seconds. If this column displays a zero rate limiting is disabled for this AP.
Management Frame Throttle Limit	Maximum number of management frames that can come from this radio in each throttle interval.
ARM/WIDS Override	Shows if ARM and Wireless IDS functions are enabled or disabled. If a radio is configured to operate in AM mode, then these functions are always enabled, regardless of this option.
Protection for 802.11b Clients	Displays whether or not protection for 802.11b clients is enabled or disabled.

Column	Description
Maximum Distance	<p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16 km.</p> <p>The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 2.4 GHz frequency band radio:</p> <ul style="list-style-type: none"> ■ 20 MHz mode: 54 km ■ 40 MHz mode: 24 km <p>If you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600 m will use default settings.</p>
Spectrum Monitoring	<p>When this parameter is enabled, it turns an AP in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p>
Assignment	<p>Displays whether or not ARM channel and power assignment has been enabled or disabled.</p>
Allowed bands for 40MHz channels	<p>Forty MHz channels may be used on the specified radio bands (802.11a or 802.11g).</p>
Client Aware	<p>Shows if the client aware feature has been enabled or disabled for this AP. If enabled, AP will not change channels when there are active clients.</p>
Max Tx Power	<p>Maximum transmission power for this AP, in dBm.</p>
Min Tx Power	<p>Minimum transmission power for this AP, in dBm.</p>
Multi Band Scan	<p>Shows if the multi-band scan feature has been enabled or disabled on this AP. If enabled, single-radio APs will try to scan across bands for Rogue AP detection.</p>

Column	Description
Rogue AP Aware	Shows if the rogue AP awareness feature has been enabled or disabled on this AP. If enabled, the AP will try to contain off-channel Rogue APs.
Scan Interval	This parameter indicates, in seconds, how often the AP will leave its current channel to scan other channels in the band if scanning is enabled.
Active Scan	<p>Displays whether or not the active scan feature is enabled.</p> <p>NOTE: This option elicits more information from nearby APs, but also creates additional management traffic on the network. Active Scan is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Aruba Support.</p>
Scanning	<p>Shows if scanning is enabled or disabled for this AP. If this option is disabled, the following other options will also be disabled:</p> <ul style="list-style-type: none"> ■ Multi Band Scan ■ Rogue AP Aware ■ Voip Aware Scan ■ Power Save Scan
VoIP Aware Scan	Shows if VoIP aware scanning is enabled or disabled. If you use voice handsets in the WLAN, VoIP Aware Scan should be enabled in the ARM profile so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that Scanning is also enabled.
Power Save Aware Scan	Shows if the power save aware scan is enabled or disabled. If enabled, the AP will not scan a different channel if it has one or more clients and is in power save mode. Default: enabled

Column	Description
Ideal Coverage Index	The Aruba coverage index metric is a weighted calculation based on the RF coverage for all Aruba APs and neighboring APs on a specified channel. The Ideal Coverage Index specifies the ideal coverage that an AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be.
Acceptable Coverage Index	For multi-band implementations, the Acceptable Coverage Index specifies the minimal coverage an AP it should achieve on its channel. The denser the AP deployment, the lower this value should be.
Free Channel Index	The current free channel index value. The Aruba Interference index metric measures interference for a specified channel and its surrounding channels. This value is calculated and weighted for all APs on those channels (including 3rd-party APs). An AP will only move to a new channel if the new channel has a lower interference index value than the current channel. Free Channel Index specifies the required difference between the two interference index values before the AP moves to the new channel. The lower this value, the more likely it is that the AP will move to the new channel.
Backoff Time	After an AP changes channel or power settings, it waits for this backoff time interval before it asks for a new channel or power setting.
Error Rate Threshold	The minimum percentage of PHY errors and MAC errors in the channel that will trigger a channel change.
Error Rate Wait Time	Minimum time in seconds the error rate on the AP has to exceed its defined error rate threshold before it triggers a channel change.
Noise Threshold	Maximum level of noise in a channel that triggers a channel change.

Column	Description
Noise Wait Time	Minimum time in seconds the noise level has to exceed the Noise Threshold before it triggers a channel change on the AP.
Minimum Scan Time	Minimum number of times a channel must be scanned before it is considered for assignment. Best practices are to configure a Minimum Scan Time between 1-20 scans.
Load aware Scan Threshold	The Load Aware Scan Threshold is the traffic throughput level an AP must reach before it stops scanning. Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high.
Mode Aware Arm	Shows if the mode-aware ARM feature has been enabled or disabled for this AP. If enabled, ARM will turn the AP into an AMs if it detects higher coverage levels than necessary. This helps avoid higher levels of interference on the WLAN. Although this setting is disabled by default, you may want to enable this feature if your APs are deployed in close proximity (e.g. less than 60 feet apart).
Scan mode	Identifies the scan mode for the AP. <ul style="list-style-type: none"> ■ all-reg-domain: The AP scans channels within all regulatory domains. This is the default setting. ■ reg-domain: Limit the AP scans to just the regulatory domain for that AP.
40 MHz intolerance	The specified setting allows ARM to determine if 40 MHz mode of operation is allowed on the 5 GHz or 2.4 GHz frequency band only, on both frequency bands, or on neither frequency band.
Honor 40 MHz intolerance	Shows if 40 MHz intolerance is enabled or disabled. If enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.

Column	Description
Legacy station workaround	Shows if interoperability for misbehaving legacy stations is enabled or disabled.
SSID enable	Shows if the SSID is enabled or disabled
ESSID	Name that uniquely identifies the Extended SSID.
Encryption	Encryption type used on this AP.
DTIM Interval	Shows the interval, in milliseconds, between the sending of DTIMs in the beacon. This is the maximum number of beacon cycles before unacknowledged network broadcasts are flushed.
Basic Rates	Lists supported 802.11a rates, in Mbps, that are advertised in beacon frames and probe responses from this AP.
Transmit Rates	Lists 802.11a rates at which the AP is allowed to send data. The actual transmit rate depends on what the client is able to handle, based on information sent at the time of association and on the current error or loss rate of the client.
Station Ageout Time	Time, in seconds, that a client is allowed to remain idle before being aged out.
Max Transmit Attempts	Maximum number of retries allowed for the AP to send a frame
RTS Threshold	Wireless clients transmitting frames larger than this threshold must issue RTS and wait for the AP to respond with CTS. This helps prevent mid-air collisions for wireless clients that are not within wireless peer range and cannot detect when other wireless clients are transmitting.

Column	Description
Short Preamble	Shows if a short preamble for 802.11b/g radios is enabled or disabled for this AP. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using short preamble. To use only long preamble, disable short preamble. Legacy client devices that use only long preamble generally can be updated to support short preamble.
Max Associations	Maximum number of wireless clients allowed to associate to the AP
Wireless Multimedia (WMM)	Shows if Wireless Multimedia (WMM) is enabled or disabled for this AP. WMM provides prioritization of specific traffic relative to other traffic in the network
Wireless Multimedia U-APSD (WMM-UAPSD) Powersave	Shows if Wireless Multimedia (WMM) UAPSD powersave is enabled or disabled.
WMM TSPEC Min Inactivity Interval	Displays the minimum inactivity timeout threshold of WMM traffic for this AP.
DSCP mapping for WMM voice AC	Displays the DSCP value used to map WMM voice traffic.
DSCP mapping for WMM video AC	Displays the DSCP value used to map WMM video traffic.
DSCP mapping for WMM best-effort AC	Displays the DSCP value used to map WMM best-effort traffic
DSCP mapping for WMM background AC	Displays the DSCP value used to map WMM background traffic.
902il Compatibility Mode	Shows if 902il compatibility mode is enabled or disabled. (This parameter only needs to be enabled for APs with associated clients using NTT DoCoMo 902iL phones.)
Hide SSID	Shows if the feature to hide a SSID name in beacon frames is enabled or disabled.

Column	Description
Deny_Broadcast Probes	When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID.
Local Probe Response	Shows if local probe response is enabled or disabled on the AP. If this option is enabled, the AP is responsible for sending 802.11 probe responses to wireless clients' probe requests. If this option is disabled, then the controller sends the 802.11 probe responses
Disable Probe Retry	If disabled, the AP will not resend probes if it does not get a response.
Battery Boost	Shows if the battery boost feature is enabled or disabled for the AP. If enabled, this feature converts multicast traffic to unicast before delivery to the client, thus allowing you to set a longer DTIM interval. The longer interval keeps associated wireless clients from activating their radios for multicast indication and delivery, leaving them in power-save mode longer and thus lengthening battery life
Drop Broadcast and Multicast	If this feature is enabled on an AP, it drops all downstream broadcast or multicast traffic to increase battery life.
WEP Key 1	Displays the static WEP key (1 of 4).
WEP Key 2	Displays the static WEP key (2 of 4).
WEP Key 3	Displays the static WEP key (3 of 4).
WEP Key 4	Displays the static WEP key (4 of 4).
WEP Transmit Key Index	Displays the key index that specifies which static WEP key is to be used.
WPA Hexkey	Displays the WPA PSK.
WPA Passphrase	Displays the WPA passphrase with which the AP generates a PSK.

Column	Description
Maximum Transmit Failures	Display the maximum number of transmission failures allowed before the client gives up.
BC/MC Rate Optimization	Shows if the AP has enabled or disabled scanning of all active stations currently associated to that AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate.
Rate Optimization for delivering EAPOL frames	Shows if the AP has enabled or disabled rate optimization for delivering EAPOL frames.
Strict Spectralink Voice Protocol (SVP)	Shows if strict SVP is enabled or disabled.
802.11g Beacon Rate	Sets the beacon rate for 802.11g for APs use a DAS. Using this parameter in normal operation may cause connectivity problems.
802.11a Beacon Rate	Sets the beacon rate for 802.11a for APs use a DAS. Using this parameter in normal operation may cause connectivity problems.
Advertise QBSS Load IE	Shows if the AP has enabled or disabled the advertising of QBSS in the load IE.
High throughput enable (SSID)	Shows if the AP has enabled or disabled the use of its high-throughput SSID in 40 MHz mode.
40 MHz channel usage	Determines if this high-throughput SSID allows high-throughput (802.11n) stations to associate.
MPDU Aggregation	Shows if the AP has enabled or disabled MPDU aggregation.
Max transmitted A-MPDU size	Shows the maximum size, in bytes, of an A-MPDU that can be sent on the AP's high-throughput SSID.
Max received A-MPDU size	Shows the maximum size, in bytes, of an A-MPDU that can be received on the AP's high-throughput SSID.

Column	Description
Min MPDU start spacing	Displays the minimum time between the start of adjacent MDPU within an aggregate MDPU, in microseconds.
Supported MCS set	Comma-separated list of MCS values or ranges of values to be supported on this high-throughput SSID.
Short guard interval in 20 MHz mode	Shows if the AP has enabled or disabled use of short guard interval in 20 MHz mode of operation.
Short guard interval in 40 MHz mode	Shows if the AP has enabled or disabled use of short guard interval in 40 MHz mode of operation.
Maximum number of spatial stream usable for STBC transmission	Controls the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the 130 Series, 170 Series and AP-105 only. The configured value will be adjusted based on AP capabilities.)
Minimum number of spatial stream usable for STBC transmission	Controls the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the 130 Series, 170 Series, and AP-105 only. The configured value will be adjusted based on AP capabilities.)
Legacy stations	Shows if the AP has enabled or disabled the legacy stations option, which controls whether or not legacy (non-HT) stations are allowed to associate with the AP's SSID. By default, legacy stations are allowed to associate. NOTE: This setting has no effect on a BSS in which HT support is not available.
Allow weak encryption	Shows if the AP has enabled or disabled the weak encryption option.

Column	Description
	The use of TKIP or WEP for unicast traffic forces the use of legacy transmissions rates. Disabling this mode prevents the association of stations using TKIP or WEP for unicast traffic. This mode is disabled by default.
Virtual AP enable	WLAN profiles configure WLANs in the form of virtual AP profiles. This parameter shows if the AP has enabled or disabled virtual APs.
Allowed band	Shows the band(s) on which to use the virtual AP: <ul style="list-style-type: none"> ■ a—802.11a band only (5 GHz) ■ g—802.11b/g band only (2.4 GHz) ■ all—both 802.11a and 802.11b/g bands (5 GHz and 2.4 GHz)
VLAN	Shows the VLAN(s) into which users are placed in order to obtain an IP address.
Forward mode	Shows the current forward mode (tunnel, bridge, split-tunnel, or decrypt-tunnel) for the virtual AP. This parameter controls whether 802.11 frames are tunneled to the controller using GRE, bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the controller, and Internet access remains local). When an AP is configured to use the decrypt-tunnel forwarding mode, that AP decrypts and decapsulates all 802.11 frames from a client and sends the 802.3 frames through the GRE tunnel to the controller, which then applies firewall policies to the user traffic. When the controller sends traffic to a client, the controller sends 802.3 traffic through the GRE tunnel to the AP, which then converts it to encrypted 802.11 and forwards to the client. Only 802.1X authentication is supported when configuring bridge or split tunnel mode.
Deny time range	Shows the time range for which the AP will deny access for a virtual AP.

Column	Description
Mobile IP	Shows if IP mobility has been enabled or disabled for the virtual AP.
HA Discovery on-association	<p>If enabled, home agent discovery is triggered on client association instead of home agent discovery based on traffic from client. Mobility on association can speed up roaming and improve connectivity for clients that do not send many uplink packets to trigger mobility (VoIP clients). Best practice is to keep this parameter disabled as it increases IP mobility control traffic between controllers in the same mobility domain. Enable this parameter only when voice issues are observed in VoIP clients.</p> <p>NOTE: <code>ha-disc-onassoc</code> parameter works only when IP mobility is enabled and configured on the controller.</p>
DoS Prevention	Shows the status of the Dos Prevention option. If enabled, virtual APs ignore deauthentication frames from clients. This prevents a successful deauth attack from being carried out against the AP. This does not affect third-party APs.
Station Blacklisting/Denylisting	Shows if the virtual AP has enabled or disabled detection of DoS attacks, such as ping or SYN floods, that are not spoofed deauth attacks.
Blacklist/Denylist Time	Shows the number of seconds that a client will be quarantined from the network after being blacklisted/denylisted.
Authentication Failure Blacklist/Denylist Time	Shows the time, in seconds, a client is blocked if it fails repeated authentication. If the virtual AP shows a value of 0, a blacklisted/denylisted client is blocked indefinitely.
Fast Roaming	Shows if the AP has enabled or disabled fast roaming.

Column	Description
Strict Compliance	If enabled, the virtual AP denies client association requests if the AP and client station have no common rates defined. Some legacy client stations which are not fully 802.11-compliant may not include their configured rates in their association requests. Such non-compliant stations may have difficulty associating with APs unless strict compliance is disabled.
VLAN Mobility	Shows if a virtual AP has enabled or disabled VLAN (Layer-2) mobility
Remote-AP Operation	Shows when the virtual AP operates on a remote AP: <ul style="list-style-type: none"> ■ always—Permanently enables the virtual AP (Bridge Mode only). This option can be used for non-802.1X bridge VAPs. ■ backup—Enables the virtual AP if the remote AP cannot connect to the controller (Bridge Mode only). This option can be used for non-802.1X bridge VAPs. ■ persistent—Permanently enables the virtual AP after the remote AP initially connects to the controller (Bridge Mode only). This option can be used for any (Open/PSK/802.1X) bridge VAPs. ■ standard—Enables the virtual AP when the remote AP connects to the controller. This option can be used for any (bridge/split-tunnel/tunnel/d-tunnel) VAPs.
Convert Broadcast ARP requests to unicast	If this option is enabled, all broadcast ARP requests are converted to unicast and sent directly to the client. You can check the status of this option using the show ap active and the show datapath tunnel command. If enabled, the output will display the letter a in the flags column.
Band Steering	Shows if band-steering has been enabled or disabled for a virtual AP.

Column	Description
	<p>ARM's band steering feature encourages dual-band capable clients to stay on the 5 GHz band on dual-band APs. This frees up resources on the 2.4 GHz band for single band clients like VoIP phones.</p> <p>Band steering reduces co-channel interference and increases available bandwidth for dual-band clients, because there are more channels on the 5 GHz band than on the 2.4 GHz band. Dual-band 802.11n-capable clients may see even greater bandwidth improvements, because the band steering feature will automatically select between 40 MHz or 20 MHz channels in 802.11n networks. This feature is disabled by default, and must be enabled in a Virtual AP profile.</p>

Related Commands

Command	Description
ap system-profile	The output of the show ap config command displays the content of the profile settings for an individual AP or AP group. Use the commands displayed in the column to the left to configure these parameters.
rf dot11g-radio-profile	This command configures AP radio settings for the 2.4 GHz frequency band, including the Adaptive Radio Management (ARM) profile and the high-throughput (802.11n) radio profile.
rf arm-profile	This command configures the Adaptive Radio Management (ARM) profile.
rf ht-radio-profile	This command configures high-throughput AP radio settings. High-throughput features use the IEEE 802.11n standard.
wlan ht-ssid-profile	This command configures a high-throughput SSID profile.
wlan virtual-ap	This command configures a virtual AP profile.

Command History

Release	Modification
ArubaOS 8.9.0.0	The following changes were made:

Release	Modification
	<ul style="list-style-type: none"> ■ The command output was modified to include 2.4GHz, 5GHz, 5GHz-secondary, and 6GHz parameters (ArubaOS 8.9.0.0 or later versions). ■ All instances of <code>Blacklist</code> and <code>Blacklisting</code> have been replaced with <code>Denylist</code> and <code>Denylisting</code> respectively. ■ All instances of <code>master</code> have been replaced with <code>conductor</code>.
ArubaOS 8.6.0.0	The output parameter <code>802.11a-secondary</code> was introduced for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

show ap consolidated-provision info

```
show ap consolidated-provision info
  ap-name <ap-name>
  ip-addr <ip-address>
  ip6-addr <ipv6-address>
```

Description

This command shows the consolidated provision details of an AP.

Parameter	Description
ap-name <ap-name>	Shows consolidated provision information based on the AP name.
ip-addr <ip-address>	Shows consolidated provision information based on the IP address of an AP.
ip6-addr <ipv6-address>	Shows consolidated provision information based on the IPv6 address of an AP.

Examples

The following example shows the consolidated provision details of an AP with name xxxxx-ap-135.

```
(host) #show ap consolidated-provision info ap-name xxxxx-ap-135
ap name: xxxxx-ap-135
ipv4 address type: dynamic
ipv4 address: 10.17.160.247
ipv4 netmask: 255.255.255.0
ipv4 gateway: 10.17.160.2
ipv4 lease: 43200
ipv4 dhcp server: 10.17.160.2
ipv4 dns server: 10.13.6.110, 0.0.0.0
ipv6 address: none
master/ conductor : 10.17.160.4
master/ conductor discover type: Provisioned manually
previous lms: none
lms addrs [0]: 10.17.160.4
```

The output of this command includes the following parameters.

Column	Description
ap name	The name of the AP for which consolidated provisioned information is required.
ipv4 address type	The IPv4 address type of the AP.
ipv4 address	The IPv4 address of the AP.
ipv4 netmask	The IPv4 subnet mask of the AP.
ipv4 gateway	The IPv4 gateway information of the AP.
ipv4 lease	The IPv4 lease information pertaining to the AP.
ipv4 dhcp server	The IPv4 DHCP server of the AP.
ipv4 dns server	The IPv4 DNS server of the AP.
ipv6 address	The IPv6 address of the AP.
master/ conductor	The IP address of the AP's Mobility Conductor.
master/ conductor discover type	The Mobility Conductor discovery (provisioning) type information for the AP
previous lms	The previous LMS IP address of the AP.
lms addr	The LMS IP address of the AP.

show ap convert-image-list

show ap convert-image-list

Description

This command shows the list of all available images for converting Campus AP or Remote AP to Instant AP.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following example shows the list of available images for AP conversion:

```
(host) [mynode] (config) #show ap convert-image-list

AP Conversion Image list
-----
Image File Name                               Build Info                                     Size
-----
-----
ArubaInstant_Draco_10.1.0.0_76943             ArubaOS version 10.1.0.0-10.1.0.0 for
Draco (jenkins@pr-hpn-cd-build04) (gcc version 5.3.0 (Buildroot 2016.02) )
#76943 SMP Tue Sep 1 04:50:43 PDT 2020
21927936
ArubaInstant_Gemini_10.1.0.0_76943           ArubaOS version 10.1.0.0-10.1.0.0 for

05:18:16 PDT 2020
17972496
```

The output of this command includes the following parameters:

Column	Description
Image File Name	The name of the available image file.
Build Info	The version number and other information of the ArubaOS build.
Size	The size of the image file .

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap convert-status-list

```
show ap convert-status-list {page <page>|start <page>}
```

Description

This command shows only the list of APs and their conversion status.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
page <page>	Number of APs to display.
start <page>	Starting AP index.

Example

The following example shows the conversion status of a particular AP image:

```
(host) [mynode] (config) #show ap convert-status-list

AP Image Conversion Status
-----
AP Name          AP Group  AP Mac          AP Serial #  AP IP
AP Type Upgrade State Start Time      End Time      Failure Count
Failure Reason
-----
-----
70:3a:0e:cc:ee:52 default  70:3a:0e:cc:ee:52  CNBQJ0Y0D4   10.65.17.124
335      Updating    2020-10-29 18:49:13      0
```

The output of this command includes the following parameters:

Column	Description
AP Name	Name of the AP selected for conversion.
AP Group	AP group of the AP selected for conversion.
AP Mac	MAC address of the AP.
AP Serial #	Serial number of the AP.

Column	Description
AP IP	IP address of the AP.
AP Type	Type of AP model.
Upgrade State	Current state of the AP's upgrade attempt .
Start Time	Time the AP started upgrading an image.
End Time	Time the AP completed the image upgrade.
Failure Count	Number of times the AP failed to upgrade the new image.
Failure Count	In the event of an image upgrade failure, this column displays the reason for the failure.

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap convert-setup-image-log

show ap convert-setup-image-log <number>

Description

This command shows the logs for moving the AP conversion images to the temporary image folder.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
<number>	The line number from the log.

Example

The following example shows the logs for moving the AP conversion images:

```
(host) [mynode] (config) #show ap convert-setup-image-log

/mswitch/bin/sapm_setup_iap_images.sh --image-file=/tmp/sapm_download_images
--image-file-is-list=1 --target-folder=/flash/apimages --platform=0
check images listing in the file /tmp/sapm_download_images
image file list:

```

The output of this command includes the following parameters:

Column	Description
AP Conversion Parameters	Shows the following conversion parameter values:
Status	Indicates if the conversion feature is enabled (active status) or disabled (inactive status). Displays one of the following values: <ul style="list-style-type: none"> ■ Active ■ Inactive
Mode	Indicates the conversion mode. Displays one of the following values: <ul style="list-style-type: none"> ■ All APs ■ Specific APs
Image Source	Indicates the image source. Displays one of the following values: <ul style="list-style-type: none"> ■ Flash: The image is copied into the controller flash. ■ Image Server: The image is on ftp, tftp, scp, or https server. ■ Activate: The controller obtains the image from Aruba Activate server. This is the recommended value. ■ None: The conversion is not active.
Max Simultaneous Converting	Indicates the number of APs that are allowed for conversion at the same time.
Current Simultaneous Converting	Indicates the number of APs currently getting converted.
Auto Reboot	Indicates whether the AP auto reboots after conversion. Displays one of the following values: <ul style="list-style-type: none"> ■ True ■ False

Column	Description
Start Time	Indicates the starting time of the conversion.
Current Status	Indicates the conversion status. Displays one of the following values: <ul style="list-style-type: none"> ■ Not Start ■ Pre-Validating ■ Pre-Validate Success ■ Pre-Validate Failed ■ Pre-Validate Timeout ■ Activate Connecting ■ Activate Connect Error ■ Downloading Image ■ Download Image Error ■ Download Image Timeout ■ Installing Image Into MD Image Folder ■ Install Image Error ■ Preload Image Is Operating ■ Updating APs ■ Update Done
AP Names Listed for Conversion	Shows the AP name listed for conversion.
AP Image Conversion AP Status Summary	These two columns list the different possible conversion states for APs, and the total number of APs in each state.
AP Image Conversion Status	This section displays the following details for each conversion attempt:
AP Name	Name of the AP selected for conversion.
AP Group	AP group of the AP selected for conversion.
AP Mac	MAC address of the AP.
AP Serial #	Serial number of the AP.
AP IP	IP address of the AP.
AP Type	Type of AP model.
Upgrade State	Current state of the AP's upgrade attempt .
Start Time	Time the AP started upgrading an image.
End Time	Time the AP completed the image upgrade.

Column	Description
Failure Count	Number of times the AP failed to upgrade the new image.
Failure Count	In the event of an image upgrade failure, this column displays the reason for the failure.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap-crash-transfer

```
show ap-crash-transfer
```

Description

This command displays info for the AP crash transfer feature, which transfers AP coredump files to the controller flash memory if no dumpserver is configured.

The command `ap system-profile <profile> dump-server <server>` specifies a server to receive a core dump generated when an AP process crashes. If no dump server is configured, issue the `ap-crash-transfer` command to save dump files to the controller flash memory.

If you define a dump server and issue the `ap-crash-server` command, the dump server configuration takes precedence, and coredump files are sent to the dump server.

Example

```
(host)[mynode] #show ap-crash-transfer
AP Crash Transfer:enabled
AP Crash folder limit:50 MB (non-editable)
```

Related Commands

Command	Description
<code>ap-crash-transfer</code>	This command allows AP coredump files to be transferred to the controller flash memory if no dumpserver is configured.

direction|start|status|switch|type|unprovisioned}
```

Description

This command shows the list of access points in the database. Many of the parameters in this command can be used together to filter a large database of information down to just the AP data you want to see. For example, you can issue the command `show ap database group <group> local status up` to view a list of local APs within a specific AP group that are reporting an **up** status. Include the **sort-by** and **sort-direction** keywords to specify how the data is sorted in the output of this command.

Parameter	Description
<code>flags <flags></code>	Shows only access points with specified flags. NOTE: Starting from ArubaOS 8.11.0.0, all available flags are included in the flags <flags> sub-parameter.
<code>group <group></code>	Shows only access points in specified AP group.
<code>inactive</code>	Shows only local access points with no active BSSIDs or wired AP interfaces.

Parameter	Description
indoor	Shows only indoor access points.
local	Shows only access points connected to this managed device.
long	Shows following additional columns for access points: <ul style="list-style-type: none"> ■ Wired MAC Address, ■ Serial # ■ Port ■ FQLN
outdoor	Shows only outdoor access points.
page <page>	Shows only specified number of access points.
sort-by	Shows access points filtered by following columns: <ul style="list-style-type: none"> ■ ap-flags ■ ap-group ■ ap-ip ■ ap-mac ■ ap-name ■ ap-serial ■ ap-type ■ fqln ■ provisioned ■ status ■ switch-ip ■ uptime
sort-direction	Shows access points in sorted in following sequence: <ul style="list-style-type: none"> ■ ascending ■ descending
start <start>	Shows access points from the specified AP index number.
status	Shows access points sorted by following status: <ul style="list-style-type: none"> ■ down ■ up
switch <switch-ip-addr>	Shows access points registered with a specified managed device.
unprovisioned	Shows only unprovisioned access points.
usb	Shows USB related parameters.

Examples

The following example shows the information of the APs in the group **default**. The output also includes a description of the flag types that may appear in the **Flags** column.

```

(host) [mynode] #show ap database group default

show ap database-summary

show ap database-summary

Description

Show a general summary of access point information for this controller.

Use this command to show the current number of active APs and Air Monitors. This command is also useful for determining how many unprovisioned APs or duplicate APs are on the network. For full details on each AP registered to a controller, use the command show ap database.

Examples

The output of this command shows that this controller can detect a total of five APs, four up, and one down.

AP Database Summary

```
-----
AP Mode           Total Up  Total Down  Total Upgrading*  Total
Rebooting*  RAP Up  RAP Down  RAP Upgrading*  RAP Rebooting*
-----
- - - - -
Access Points    4        1        0                0
 0      0      0        0                0
Air Monitors     0        0        0                0
 0      0      0        0                0
Wired Access Points 0        0        0                0
 0      0      0        0                0
Mesh Portals     0        0        0                0
 0      0      0        0                0
Mesh Points      0        0        0                0
 0      0      0        0                0
Spectrum Monitors 1        1        0                0
 0      0      0        0                0

*Upgrading and Rebooting counts only reflect APs registered on this controller.
```

The output of this command includes the following information:

Parameter	Description
Total Up	Total number of APs with an <i>up</i> status.
Total Down	Total number of APs with a <i>down</i> status.
IPSEC Up	Total number of APs with an active (up) IPsec tunnel.
IPSEC Down	Total number of APs with an inactive (down) IPsec tunnel.

Description

This command displays the AP debugging information. Click parameter links to view the corresponding show commands.

Parameter	Description
<u>11ad-radio-bond-stats</u>	Shows the aggregate 11ad radio bond debug statistics of an AP.
<u>acl-table</u>	Shows ACL table in AP datapath.
<u>aid-table</u>	Shows the association ID table.
<u>airmatch</u>	Shows information about AirMatch.
<u>airmatch-report</u>	Shows information about AirMatch updates on an AP.
<u>anyspot-stats</u>	Shows anyspot statistics of a radio on an AP.
<u>backup-vap</u>	Shows backup VAP for an AP.
<u>bandwidth-management</u>	Shows bandwidth management information for clients.
<u>ble-action-action-status</u>	Shows the action status for BLE devices seen by the AP.
<u>ble-config</u>	Shows the Bluetooth Low Energy (BLE) configuration of the AP.
<u>ble-counter</u>	Shows the packet counters for BLE devices seen by the AP.
<u>ble-input-filter-stats</u>	Shows the input-filter information in the BLE table.
<u>ble-log</u>	Shows the BLE debug logs of the AP.
<u>ble-table</u>	Shows the statistics for BLE devices seen by the AP.
<u>ble-update-status</u>	Shows the configuration update status for BLE devices seen by the AP.
<u>bss-config</u>	Shows the configuration for each BSSID of an AP.
<u>bss-stats</u>	Shows debug and troubleshooting statistics from a specific BSSID of an AP.
<u>bucketmap-state</u>	Shows clients in different buckets.
<u>client-death-reason-counters</u>	Shows the aggregate client death reason counters.
<u>client-info</u>	Shows all the details of a specific client in WLAN driver.
<u>client-kickout-logs</u>	Shows the reasons why clients got deauthenticated due to consecutive TX failures.
<u>client-mgmt-counters</u>	Shows the message counters.
<u>client-stats</u>	Shows the detailed statistics about a client from an AP.

Parameter	Description
<u>client-table</u>	Shows clients associated with an AP.
<u>client-trace</u>	Shows the counts of different types of management data frames traced from a client MAC address.
<u>client-trace clients</u>	Shows debug client trace for all registered clients in an AP.
<u>cluster-counters</u>	Shows the controller cluster statistics.
<u>config-msg-history</u>	Shows recent configuration messages sent and received by an AP.
<u>counters</u>	Shows AP reboot/bootstrap counters.
<u>crash-info</u>	Shows crash log information for an individual AP.
<u>crypto</u>	Shows the debug crypto logs for an AP.
<u>datapath</u>	Shows datapath tunnel parameters of an AP or AP group.
<u>dot11r efficiency</u>	Shows all the r1 keys that are stored in an AP and the hit/miss rate of r1 keys cached on an AP before a Fast BSS Transition roaming.
<u>dot11r state</u>	Shows all the r1 keys that are stored in an AP.
<u>driver-log</u>	Shows an AP's driver logs.
<u>esl-status</u>	Shows the ESL status of an AP.
<u>gre-tun-stats</u>	Shows GRE tunnel packet statistics of an AP.
<u>gsm-counters</u>	Shows the GSM counters of an AP or AP group.
<u>hotspot statistics</u>	Shows statistics of ANQP/H2QP information for the specified BSSID.
<u>iot-sniffer</u>	Shows sniffer information on the AP.
<u>ipc forwarding-statistics</u>	Shows an AP's ipc forwarding statistics.
<u>power-table</u>	Shows an AP's Power limit table.
<u>radio-stats</u>	Shows AP's aggregate radio debug statistics.

Command History

Release	Modification
ArubaOS 8.8.0.0	The <code>iot-sniffer</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on managed devices.

show ap debug 11ad-radio-bond-stats

```
show ap debug 11ad-radio-bond-stats  
  ap-name <ap-name> | ip-addr <ip-addr>] ip6-addr <ip6-addr>
```

Description

This command displays the aggregate 11ad radio bond debug statistics of an AP.

Parameter	Description
ap-name <ap-name>	Show debugging information for a specific AP.
ip-addr <ip-addr>	Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show debugging information for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug acl-table

```
show ap debug acl-table {[ap-name <ap-name>]|[ip-addr <ip-addr>]|[ip6-addr <ip6-addr>]}
```

Description

This command shows ACL table in AP datapath.

Parameter	Description
ap-name <ap-name>	Shows ACL table in AP datapath of an AP specified by AP name.
ip-addr <ip-addr>	Shows ACL table in AP datapath of an AP specified by IP address.
ip6-addr <ip6-addr>	Shows ACL table in AP datapath of an AP specified by IPv6 address.

Example

The following example shows ACL table in AP datapath for an AP named ap-205:

```
(host) [mynode] #show ap debug acl-table ap-name ap-205

acl_2700: entries 21@7680, role, ACL 2700:, acl_flags:0000

show ap debug aid-table

show ap debug aid-table bssid <bssid> [advanced]

Description

This command shows the association ID table.

Parameter	Description
bssid <bssid> [advanced]	Shows association ID table of the specified BSSID.

Example

The following example shows association ID table for the BSSID 00:1a:1e:aa:bb:cc:

```
(host) [mynode] #show ap debug aid-table bssid 00:1a:1e:aa:bb:cc [advanced]
AP Association-ID Table for BSSID: d8:c7:c8:38:fc:f5
-----

show ap debug airmatch

```
show ap debug airmatch channel-lists | feasibility | nbr | reporting-radio | status  
  {[ap-name <ap-name>]}|[ip-addr <ip-addr>]}|[ip6-addr <ip6-addr>]}
```

Description

This command displays information about AirMatch.

Parameter	Description
channel-lists	Shows channel lists.
feasibility	Shows radio feasibility data.
nbr	Shows the list of neighboring radios.
reporting-radio	Shows the reporting radio details.
status	Shows the status of the radios.
ap-name <ap-name>	Shows AirMatch data on an AP specified by AP name.
ip-addr <ip-addr>	Shows AirMatch data on an AP specified by IP address.
ip6-addr <ip6-addr>	Shows AirMatch data on an AP specified by IPv6 address.

Example

The following example shows information about AirMatch reporting radio of an AP that is identified by its name.

```

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.10.0.0	The output of the command was modified to include the <code>Probe Type</code> parameter under the AirMatch Reporting Radio Band 2.4GHz table.
ArubaOS 8.9.0.0	The following changes were introduced: <ul style="list-style-type: none"> ■ The Radio 2 interface was displayed for 6 GHz band on Wi-Fi 6E APs. ■ The command output was modified to include 6 GHz values for Wi-Fi 6E APs. ■ The <code>show ap debug airmatch channel-lists ap-name <ap-name></code> command output was modified to include <code>u</code> channel flag and 6 GHz data for Wi-Fi 6E APs. ■ All instances of <code>Blacklist Reason</code> have been replaced with <code>Blocked Reason</code>.
ArubaOS 8.6.0.0	A new interface for Radio 2 will be displayed for AP-555 access points.
ArubaOS 8.2.1.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap debug airmatch-report

```
show ap debug airmatch-report {[ap-name <ap-name>]}|[ip-addr <ip-addr>]|[ip6-addr <ip6-addr>]
```

Description

This command displays information about AirMatch updates on an AP. Issue this command to show AirMatch measurement settings applied to the selected AP, as well as information about the last update for different AirMatch reports.

Parameter	Description
ap-name <ap-name>	Shows AirMatch data on an AP specified by AP name.
ip-addr <ip-addr>	Shows AirMatch data on an AP specified by IP address.
ip6-addr <ip6-addr>	Shows AirMatch data on an AP specified by IPv6 address.

Example

The following example shows the latest AirMatch statistics on the AP **Floor2-west**.

```
(Host) [node] #show ap debug airmatch-report ap-name Floor2-west

AirMatch measure info
-----
report period (mins)  measure duration (mins)  measure state  report enabled
-----
5                    5                        in progress   yes
AirMatch report info
-----
AirMatch Report Type  Count  Last Update Time
-----
reporting radio       2      2016-07-05 22:01:12
neighbors             8000   2016-07-06 22:46:09
feasibility           730    2016-07-06 22:47:44
event                 0      no update
```

The output of this command includes the following information:

Column	Description
report period	The AirMatch report period in the ap system profile
measure duration	The AirMatch measure duration in the ap system profile

Column	Description
<code>measure state</code>	The current AirMatch measurement state. Possible states are in progress , stopped , and waiting .
<code>Report enabled</code>	This value is expected to be the same as the airmatch-report-enabled setting in the ap system profile.

Related Commands

Command	Description

show ap debug anyspot-stats

```
show ap debug anyspot-stats {[ap-name <ap-name>]} [[ip-addr <ip-addr>]] [[ip6-addr <ip6-addr>]] {radio <radio>}
```

Description

This command shows anyspot statistics of a radio on an AP.

Parameter	Description
ap-name <ap-name>	Shows anyspot statistics of a radio on an AP specified by AP name.
ip-addr <ip-addr>	Shows anyspot statistics of a radio on an AP specified by IP address.
ip6-addr <ip6-addr>	Shows anyspot statistics of a radio on an AP specified by IPv6 address.
radio <radio>	Shows ACL table in AP datapath of AP specified by radio ID (either 0,1 or 2).

Example

The following example shows anyspot is disabled on radio 0 of an AP named ap-205:

```
(host) [mynode] #show ap debug anyspot-stats ap-name ap-205 radio 0
Anyspot is disabled on the specified radio!
```

Related Commands

Command	Description
wlan anyspot-profile	The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.

show ap debug backup-vap

```
show ap debug backup-vap {[ap-name <ap-name>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>]}
```

Description

This command shows backup VAP for an AP.

Parameter	Description
ap-name <ap-name>	Shows backup VAP for an AP for specified AP name.
ip-addr <ip-addr>	Shows backup VAP for an AP for specified IP address.
ip6-addr <ip6-addr>	Shows backup VAP for an AP for specified IPV6 address.

Example

The following example shows backup VAP for an AP named ap-205:

```
(host) [mynode] #show ap debug backup-vap ap-name ap-205

AP backup ssid debug information
-----
Item      Value
-----
Host      192.192.189.1
Config    Mode:off  Band:all
Run:      Telnet[N] Enable[0] aruba015[N] aruba115[N]
```

Command History:

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

show ap debug bandwidth-management

```
show ap debug bandwidth-management [ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]
```

Description

This command shows bandwidth management information for clients.

Parameter	Description
ap-name <ap-name>	Name of the access point.
ip-addr <ip-addr>	IP address of the access point.
ip6-addr <ip6-addr>	IPv6 address of the access point

Examples

The output of this command shows interface and shaping and interface policy for this AP.

```
(host) #show ap debug bandwidth-management ap-name amit-ap-105
Interface :wifi0
Shaping policy:Default-access (no stats)
Interface :wifi1
Shaping policy:Default-access (no stats)
```

show ap debug ble-action-status

```
show ap debug ble-action-status {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command displays the action status for BLE devices seen by the AP.

Syntax

Parameter	Description
ap-name	Displays the action status for BLE devices seen by the AP based on the AP name.
ip-addr	Displays the action status for BLE devices seen by the AP based on the IPv4 address.
ip6-addr	Displays the action status for BLE devices seen by the AP based on the IPv6 address.

Example

The output of this command displays the action status for BLE devices seen by the AP.

```
(host) #show ap debug ble-action-status ap-name ap325

BLE Device Action Table
-----

Pending Actions
-----
BLE Device MAC  ActionId  Operation  Characteristic  Value  Status
-----

Completed Actions
-----
BLE Device MAC  ActionId  Operation  Characteristic  Value  Status
-----
```

show ap debug ble-config

```
show ap debug ble-config
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command displays the Bluetooth Low Energy (BLE) configuration of the AP. In addition, the command displays the update interval to the Beacon Management Console (BMC), BLE token, AP Beacon (APB) status, the last update time to BMC, and the beacon MAC for which the last update was sent.

This command is supported in 210 Series, 220 Series (with external BLE USB), and 320 Series.

Parameter	Description
ap-name	Displays the BLE configuration of an AP for a specific AP based on the AP name.
ip-addr	Displays the BLE configuration of an AP for a specific AP based on the IPv4 address.
ip6-addr	Displays the BLE configuration of an AP for a specific AP based on the IPv6 address.

Example

The output of this command displays the update interval to the Beacon Management Console (BMC), BLE token, AP Beacon (APB) status, the last update time to BMC, and the beacon MAC for which the last update was sent.

```
(host) #show ap debug ble-config ap-name ap325

```

Notes: - Setting Message Selector value to 0x0 will cause the APB to function improperly. Use the knob with caution.

- An active Meridian Beacons Management profile will override the iBeacon configuration setting on an AP's BLE radio.
- Uplink status is applicable only when console is set to dynamic

For APBs of type LS-BT1USB, applied operational mode is Beaconing if ap system profile setting is either Persistent or Dynamic.

show ap debug ble-counters

```
show ap debug ble-counters
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command displays the packet counters for BLE devices seen by the AP. In addition, the command displays if any high power beacons are seen, the time at which configuration update was received for the beacons from the BMC and the updated response sent back.

This command is supported in 210 Series, 220 Series (with external BLE USB), and 320 Series.

Parameter	Description
ap-name	Displays the packet counters for BLE devices seen by the AP for a specific AP based on the AP name.
ip-addr	Displays the packet counters for BLE devices seen by the AP for a specific AP based on the IPv4 address.
ip6-addr	Displays the packet counters for BLE devices seen by the AP for a specific AP based on the IPv6 address.

Example

The output of this command displays the packet counters for BLE devices seen by the AP. In addition, it displays if any high power beacons are seen, the time at which configuration update was received for the beacons from the BMC and the updated response sent back.

```
(host) #show ap debug ble-counters ap-name ap325

show ap debug ble-table

```
show ap debug ble-table
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
  ibeacon
```

Description

This command displays the statistics for BLE devices seen by the AP. In addition, the command displays beacons seen by the APB, each of the beacons' attributes such as the Major-Minor numbers, Batter Level, Firmware version, time since the beacon was last heard by the APB.

This command is supported in 210 Series, 220 Series (with external BLE USB), and 320 Series.

Parameter	Description
ap-name	Displays the statistics for the BLE devices seen by the AP for a specific AP based on the AP name.
ip-addr	Displays the statistics for the BLE devices seen by the AP for a specific AP based on the IPv4 address.
ip6-addr	Displays the statistics for the BLE devices seen by the AP for a specific AP based on the IPv6 address.
ibeacon	Displays the statistics for the BLE devices seen by the AP for a specific AP based on the ibeacon info.

Example

The output of this command displays the statistics for BLE devices seen by the AP.

```
(host) #show ap debug ble-table ap-name ap325

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug ble-tag-report

```
show ap debug ble-tag-report {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command displays the Bluetooth Low Energy (BLE) asset tags that are reported to the Beacon Management Console (BMC). The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Displays the BLE asset tags for a specific AP based on the AP name.
ip-addr <ip-addr>	Displays the BLE asset tags for a specific AP based on the IPv4 address.
ip6-addr <ip6-addr>	Displays the BLE asset tags for a specific AP based on the IPv6 address.

This command is supported in 210 Series, 220 Series (with external BLE USB), and 320 Series.

Example

```
(host) #show ap debug ble-tag-report ap-name ap325
```

show ap debug ble-update-status

```
show ap debug ble-update-status
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command displays the configuration update status for BLE devices seen by the AP. In addition, the command displays the active versus desired configuration based on the configuration received from the BMC (if any).

This command is supported in 210 Series, 220 Series (with external BLE USB), and 320 Series.

Parameter	Description
ap-name	Displays the configuration update status for BLE devices seen by the AP based on the AP name.
ip-addr	Displays the configuration update status for BLE devices seen by the AP based on the IPv4 address.
ip6-addr	Displays the configuration update status for BLE devices seen by the AP based on the IPv6 address.

Example

The output of this command displays the configuration update status for BLE devices seen by the AP. In addition, the command displays the active versus desired configuration based on the configuration received from the BMC (if any).

```
(host) #show ap debug ble-update-status ap-name ap325

show ap debug bss-config

```
show ap debug bss-config [ap-name <ap-name>|bssid <bssid>||essid <essid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>|port <port>/<slot>]
```

Description

Shows the configuration for each BSSID of an AP. This information can be used to troubleshoot problems on an AP.

Parameter	Description
ap-name <ap-name>	Filter the AP Config table by AP name.
bssid <bssid>	Filter the AP Config table by BSSID. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.
essid <essid>	Filter the AP Config table by ESSID. An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks.
ip-addr <ip-addr>	Filter the AP Config table by IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Filter the AP Config table by IP address by entering an IPv6 IP address in dotted-decimal format.
port <port>/<slot>	Filter the AP Config table by port and slot numbers. The slot and port numbers should be separated by a forward slash (/).

Examples

The following example shows the AP configuration table for a specific BSSID.

```
(host) #show ap debug bss-config

```

The output of this command includes the following information:

Column	Description
bss	Basic Service Set (BSS) identifier, which is usually the AP's MAC address.

Column	Description
ess	Extended Service Set (ESS) identifier; a user-defined name for a wireless network.
vlan	The BSSID's VLAN number.
IP	The AP's IP address.
phy 8.9.0.0) (For versions prior to ArubaOS	One of the following 802.11 types <ul style="list-style-type: none"> ■ a ■ a-HT (high-throughput) ■ g ■ g-HT (high-throughput)
band/ht-mode/bandwidth 8.9.0.0) (For versions prior to ArubaOS	The AP radio type displayed by radio band/throughput type/channel bandwidth. Possible values for each type are as follows: <ul style="list-style-type: none"> ■ band—2.4GHz, 5GHz, or 6GHz ■ ht-mode—HT, VHT, or HE ■ bandwidth—20MHz, 40MHz, 80MHz, 80+80MHz, or 160MHz
type	This column shows if the BSSID is for an access point (ap) or an air monitor (am).
fw-mode	The configured forward mode for the AP's virtual AP profile.

Column	Description
	<ul style="list-style-type: none"> ■ bridge: Bridge locally ■ split-tunnel: Tunnel to controller or NAT locally ■ tunnel: Tunnel to controller
max-cl	The maximum number of clients allowed for this BSSID.
preamble	Shows if short preambles are enabled for 802.11b/g radios. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using a short preamble.
MTU	Maximum Transmission Unit (MTU) size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.
status	Shows if this BSSID is enabled or disabled.

Column	Description
wmm	Shows if the BSSID has enabled or disabled WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF) WMM provides prioritization of specific traffic relative to other traffic in the network.

Related Commands

Command	Description
show ap bss-table	This command shows the Basic Service Set (BSS) table of an AP.

Command History

Release	Modification
ArubaOS 8.9.0.0	The following changes were introduced: <ul style="list-style-type: none"> Replaced <code>phy</code> with <code>band/ht-mode/bandwidth</code> parameter in the command output. Replaced <code>g</code> and <code>a</code> with 2.4GHz and 5GHz values in the command output. Added 6GHz value in the command output for Wi-Fi 6E APs. Added <code>x</code> flag in the command output parameter for Wi-Fi 6E APs.
ArubaOS 8.0.0.0	Command introduced.

The output of this command includes the following information:

Column	Description
Tx Frames Rcvd	Number of transmitted frames that were received.
Tx Bcast Frames Rcvd	Number of transmitted broadcast frames that were received.
Tx Frames Dropped	Number of transmitted frames that were dropped.
Tx Bcast Frames Dropped	Number of transmitted broadcast frames that were dropped.
Tx Frames Transmitted	Number of frames successfully transmitted.
Tx Bytes Rcvd	Number of transmitted bytes received.

Column	Description
Tx Bytes Transmitted	Number of transmitted bytes.
Tx Time Frames Rcvd	Number of times transmitted frames were received.
Tx Time Frames Dropped	Number of times transmitted frames were dropped.
Tx Time Frames Transmitted	Number of times frames were transmitted.
Tx Success With Retry	Number of frames that were successfully transmitted after being retried.
Tx Multiple retries	Number of frames that were successfully transmitted after being retried multiple times.
Tx Mgmt Frames	Number of management frames transmitted.
Tx Beacons Transmitted	Number of beacons transmitted.
Tx Probe Responses	Number of transmitted probe responses.
Tx Data Transmitted Retried	Number of retried data frames.
Tx Data Transmitted	Number of transmitted data frames.
Tx Data Frames	Number of transmitted data frames.
Tx Broadcast Data Frames In	Number of broadcast data frames received by the AP from wired interface to be transmitted in the air.
Tx Data Bytes Transmitted	Total data bytes received by an AP from its wired interface to be transmitted over the air.
Tx Data Bytes	Total data bytes transmitted by the AP over the air.
Tx Time BC/MC Data	Total time spent transmitting broadcast/multicast frames.
Tx Time Data dropped	Total time spent transmitting dropped frames.
Tx Time Data	Total time spent sending frames received for transmission, including the frames that were dropped after retrying.
Tx Broadcast Data Frames Sent	Broadcast data frames transmitted by the AP.
Tx Multicast Data Frames	Multicast data frames transmitted by the AP.

Column	Description
Tx DMO Multicast	<p>NOTE: This counter applies to APs in decrypt-tunnel or split forwarding modes only. They may also increment for Instant APs in bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.</p>

Column	Description
	also increment for Instant APsin bridge forwarding mode if the Instant AP performs bridge-mode multicast conversion.
Tx Unicast Data Frames	Number of transmitted unicast data frames.
Tx RTS Success	Number of Ready To Send (RTS) frames successfully transmitted.
Tx RTS Failed	Number of Ready To Send (RTS) frames that were not successfully transmitted
Tx CTS Frames	Number of Clear-to-Send (CTS) frames transmitted.
Tx Dropped After Retry	Number of frames dropped after an attempted retry.
Tx Dropped No Buffer	Number of frames dropped because the AP's buffer was full.
Tx Missed ACKs	Number of retries triggered because an acknowledgement was not received.
Tx EAPOL Frames	Number of EAPOL frames transmitted
TX STBC Frames	Number of transmitted frames with Space-time block coding (STBC) enabled.
TX LDPC Frames	Number of transmitted frames with Low Density Parity Check (LDPC) enabled.
Tx WMM	<p>Number of Wi-fi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <ul style="list-style-type: none"> ■ Tx WMM [BE]: Best Effort ■ Tx WMM [BK]: Background ■ Tx WMM [VO]: VoIP ■ Tx WMM [VI]: Video
Tx Data <value> Mbps	Number of frames transmitted at the specified rate, (Mbps).
Tx Data Bytes <value> Mbps	Number of bytes of data transmitted at the specified rate, (Mbps).
UAPSD OverflowDrop	Number of packets dropped due to Unscheduled Automatic Power Save Delivery (U-APSD) overflow.

Column	Description
Tx Mgmt Bytes	Total management frame bytes transmitted.
Tx Beacons Bytes	Total number of Beacon frame bytes transmitted.
Tx AMSDU pkt count	Total number of AMSDU bytes transmitted.
Tx Data Frames/Bytes 24 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (12-24)
Tx Data Frames/Bytes 36 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (24-36)
Tx Data Frames/Bytes 54 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (36-54)
Tx Data Frames/Bytes 72 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (54-72)
Tx Data Frames/Bytes 108 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (72-108)
Tx Data Frames MCS 0	Total number of data frames transmitted at rate of MCS 0
Tx Data Frames MCS 1	Total number of data frames transmitted at rate of MCS 1
Tx Data Frames MCS 2	Total number of data frames transmitted at rate of MCS 2
Tx Data Frames MCS 3	Total number of data frames transmitted at rate of MCS 3
Tx Data Frames MCS 4	Total number of data frames transmitted at rate of MCS 4
Tx Data Frames MCS 5	Total number of data frames transmitted at rate of MCS 5
Tx Data Frames MCS 6	Total number of data frames transmitted at rate of MCS 6
Tx Data Frames MCS 7	Total number of data frames transmitted at rate of MCS 7
Tx Data Frames MCS 8	Total number of data frames transmitted at rate of MCS 8
Tx Data Frames MCS 9	Total number of data frames transmitted at rate of MCS 9

Column	Description
Tx Data Frames Legacy	Total number of data frames transmitted at legacy rate
Tx Data Frames MCS	Total number of data frames transmitted at MCS rate
Tx Data Frames NSS1	Total number of data frames transmitted 1 spacial stream
Tx Data Frames NSS2	Total number of data frames transmitted with 2 spacial stream
Tx Data Frames NSS3	Total number of data frames transmitted with 3 spacial stream
Tx Data Frames Short-GI (HALF)	Total number of data frames transmitted with short GI
Tx Data Frames Long-GI (FULL)	Total number of data frames transmitted with long GI
Tx Data Frames BW20	Total number of data frames transmitted at 20 Mhz
Tx Data Frames BW40	Total number of data frames transmitted at 40 Mhz
Tx Data Frames BW80	Total number of data frames transmitted at 80 Mhz
Tx Data Frames BW160	Total number of data frames transmitted at 160 Mhz
Rx Last SNR	The last recorded signal-to-noise ratio.
Rx Last SNR CTL0	The signal-to-noise ratio for the last received data packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR CTL1	The signal-to-noise ratio for the last received data packet on the secondary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR CTL2	The signal-to-noise ratio for the last received data packet on the secondary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last ACK SNR	Signal-to-noise ratio for the last received ACK packet.

Column	Description
Rx Last ACK SNR CTL0	Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last ACK SNR CTL1	Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last ACK SNR CTL2	Signal-to-noise ratio for the last received ACK packet on the primary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Frames Received	Number of frames received.
Rx retry frames	Number of retried frames received.
Rx data frames retried	Number of retried data frames received.
Rx Data Frames	Number of data frames received.
Rx Data Bytes	Number of data bytes received.
Rx Time Data	Total time spent on frames successfully received.
Rx Duplicate Frames	Number of duplicate frames received.
Rx Broadcast Data Frames	Number of broadcast frames received.
Rx Multicast Data Frames	Number of multicast frames received.
Rx Unicast Data Frames	Number of unicast frames received.
Rx Null Data Frames	Number of null data frames received.
Rx Mgmt Frames	Number of management frames received.
Control Frames	Number of control frames received.
Frames To Me	Number of frames received that are addressed to the specified BSSID.
Bytes To Me	Number of bytes received that are addressed to the specified BSSID.
Time To Me	Total time spent receiving frames sent to a specified BSSID.
Rx Probe Requests	Number of probe requests received.

Column	Description
RX PS Poll Frames	Power-Save Poll (PS-Poll) frames received. When a client exits a power-saving mode, it transmits a PS-Poll frame to the AP to retrieve any frames buffered while it was in power-saving mode.
RX STBC Frames	Number of received frames with STBC enabled.
RX LDPC Frames	Number of received frames with LDPC enabled.
Rx Data <value> Mbps	Number of frames received at the specified rate, (Mbps).
Rx Data Bytes <value> Mbps	Number of bytes of data received at the specified rate, (Mbps).

Related Commands

Command	Description
show ap bss-table	This command shows the Basic Service Set (BSS) table of an AP.

Command History

Release	Modification
ArubaOS 8.3.0.0	The output of this command now includes MCS bucket mapping information channel width, number of spatial streams, and guard interval information of 802.11ac APs.
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug bucketmap-state

```
show ap debug bucketmap-state
  essid <ssid>
  filter-by {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr> | ip6-addr
<ip6-addr>}
  uac {bucket <bucket> | dormant {ssid <ssid> | filter-by {ap-name <ap-name> |
  bssid <bssid> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
  verbose {ssid <ssid> | filter-by {ap-name <ap-name> | bssid <bssid> | ip-addr
<ip-addr> | ip6-addr <ip6-addr>}} | uac-ip <uac-ip> | uac-ip6 <uac-ip6>}
  verbose {ssid <ssid> | filter-by {ap-name <ap-name> | bssid <bssid> | ip-addr
<ip-addr> | ip6-addr <ip6-addr>} | uac {bucket <bucket> | dormant {ssid <ssid> |
filter-by {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr> | ip6-addr <ip6-
addr>}}}}}
```

Description

This command shows clients in different buckets.

Parameter	Description
ssid <ssid>	Shows clients filtered by ESSID.
filter-by {ap-name <ap-name> bssid <bssid> ip-addr <ip-addr> ip6-addr <ip6-addr>}	Shows clients filtered by name of AP, BSSID, IP address or IPv6 address.
uac {bucket <bucket> dormant {ssid <ssid> filter-by {ap-name <ap-name> bssid <bssid> ip-addr <ip-addr> ip6-addr <ip6-addr>} verbose {ssid <ssid> filter-by {ap-name <ap-name> bssid <bssid> ip-addr <ip-addr> ip6-addr <ip6-addr>}} uac-ip <uac-ip> uac-ip6 <uac-ip6>}}	Shows clients filtered by bucket index, dormancy, IP address, or IPv6 address.
verbose {ssid <ssid> filter-by {ap-name <ap-name> bssid <bssid> ip-addr <ip-addr> ip6-addr <ip6-addr>} uac {bucket <bucket> dormant {ssid <ssid> filter-by {ap-name <ap-name> bssid <bssid> ip-addr <ip-addr> ip6-addr <ip6-addr>}}}}	Shows clients filtered by bucket index, dormancy, IP address, or IPv6 address

Example

Access the CLI and use the following command to show clients filtered by the ESSID **test**:

```
(host) [mynode] #show ap debug bucketmap-state essid test

Essid "test"
Number of updates 1; Time since last update 1h:19m:24s
Activations: New Bmap=0, Node Down=0
Bucketmap State
-----
Index  UAC                               status
-----  ---  -----
0      10.15.146.3 (self) Up
1      10.15.146.4 Up
2      10.15.146.5 Up
3      10.15.146.6 Up
Stations in buckets for Essid SriniZone1TestEssid
-----
BucketIndex  MAC  BSSID  AID  AP Name  UAC IP
-----  ---  -----  ---  -----  -----
Total Stations=0 Total Active=0 Total Dormant=0
```

show ap debug client-info

```
show ap debug client-info <client-mac>
```

Description

This command displays all the details of a specific client in WLAN driver, for client debugging.

Parameter	Description
client-mac	The client MAC address.

Examples

The example below displays the output of the `show ap debug client-info` command:

```
(host) [mynode] #show ap debug client-info client-mac 78:31:c1:be:93:74
```

show ap debug client-kickout-logs

```
show ap debug client-kickout-logs {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>} {radio <radio>}
```

Description

This command displays the last 12 occurrences of the client kickout (deauthentication) logs per radio that occurs due to consecutive Tx failures on APs.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name> ip-addr <ip-addr> ip6-addr <ip6-addr>	Shows debug client kickout logs for specified AP name, IPv4 address, or IPv6 address.
radio <radio>	Shows information for a specific radio type. The valid values are 0, 1, and 2.

This command is supported in 530 Series, 550 Series, 630 Series, and 650 Series access points.

Example

The following example shows the client kickout logs on AP-535.

```
(host) [mynode] #show ap debug client-kickout-logs ap-name ap535 radio 0
Client kickout due to consecutive Tx failures

show ap debug client-mgmt-counters

show ap debug client-mgmt-counters

Description

This command shows the message counters. This command shows the numbers of each type of message sent from a client to an AP. Use this information to troubleshoot problems on an AP.

Examples

The following example shows the client management counters.

```
(host) [mynode] #show ap debug client-mgmt-counters

The output of this command includes the following information:

Column	Description
Frames Rcvd For TX	Number of frames received for transmission.
Tx Frames Dropped	Number of transmission frames that were dropped.
Frames Transmitted	Number of frames successfully transmitted.
Success With Retry	Number of frames that were transmitted after being retried.
Tx Mgmt Frames	Number of management frames transmitted.
Tx Probe Responses	Number of transmitted probe responses.
Tx Data Frames	Number of transmitted data frames.
Tx CTS Frames	Number of clear-to-send (CTS) frames transmitted.
Dropped After Retry	Number of frames dropped after an attempted retry.
Dropped No Buffer	Number of frames dropped because the AP's buffer was full.
Missed ACKs	Number of missed acknowledgements (ACKs)
Long Preamble	Number of frames sent with a long preamble.
Short Preamble	Number of frames sent with a short preamble.
Tx EAPOL Frames	Number of Extensible Authentication Protocol over LAN (EAPOL) frames transmitted.
Tx <n> Mbps	Number of frames transmitted at <n> Mbps, where <n> is a value between 6 and 300.
Tx WMM	<p>Number of Wifi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <ul style="list-style-type: none"> ▪ Tx WMM [BE]: Best Effort ▪ Tx WMM [BK]: Background ▪ Tx WMM [VO]: VoIP ▪ Tx WMM [VI]: Video
UAPSD OverflowDrop	Number of packets dropped due to Unscheduled Automatic Power Save Delivery (U-APSD) overflow.

Column	Description
Tx Data Frames/Bytes 24 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (12-24)
Tx Data Frames/Bytes 36 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (24-36)
Tx Data Frames/Bytes 54 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (36-54)
Tx Data Frames/Bytes 72 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (54-72)
Tx Data Frames/Bytes 108 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (72-108)

show ap debug client-table

```
show ap debug client-table [ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]
```

Description

This command shows clients associated with an AP. The **Tx_Rate**, **Rx_Rate**, **Last_ACK_SNR**, and **Last_Rx_SNR** columns shown in the output of this command show valuable troubleshooting information for clients trying to connect to a specific AP. Use this command to verify that the transmit (Tx_Rate) and receive (Rx_Rate) rates are not too low, and that the SNR is acceptable.

Parameter	Description
ap-name <ap-name>	Filters the client table by AP name.
bssid <bssid>	Filters the client table by BSSID. This will print clients on top from given BSSID.
ip-addr <ip-addr>	Filters the client table by AP IP address.
ip6-addr <ip6-addr>	Filters the client table by AP IPv6 address.

Examples

The example below displays the AP configuration table for a specific BSSID. In this example, the output is divided into multiple sections to better fit on the pages of this document. In the actual CLI, it appears in a single, long table.

```
(host) #show ap debug client-table ap-name apname1
Client Table

E - Beamformee; e - Beamformer
HT_State shows client's original capabilities (not operational capabilities)

```

The output of this command includes the following information:

Parameter	Description
MAC	MAC address of a client.
ESSID	ESSID used by the client. An ESSID is a user-defined name for a wireless network.
BSSID	BSSID for the client.
Assoc_State	The associated state column shows whether or not the client is currently authorized and/or associated with the AP.
HT_State	Shows information about the client's high-throughput or very-high throughput transmission type. The description for each of the flags that can appear in this column follows the output of the command. <ul style="list-style-type: none"> ▪ A - LDPC Coding ▪ W - 40MHz ▪ S - Short GI 40 ▪ s - Short GI 20 ▪ D - Delayed BA ▪ G - Greenfield ▪ R - Dynamic SM PS ▪ Q - Static SM PS ▪ N - A-MPDU disabled ▪ B - TX STBC ▪ b - RX STBC ▪ M - Max A-MSDU ▪ I - HT40 Intolerant ▪ C - 160MHz ▪ c - 80MHz ▪ V - Short GI 16 ▪ v - Short GI 80 ▪ E - Beamformee

Parameter	Description
	<ul style="list-style-type: none"> ▪ e - Beamformer
AID	802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.
PS_State	Powersave state, showing if the AP is in the awake or power-save state.
UAPSD	<p>Shows the U-APSD queue statuses in the following comma-separated format: (<VO>,< VI>,< BK>, <BE>,< Max SP>,<Q Len>).</p> <ul style="list-style-type: none"> ▪ VO: If 1, UAPSD is enabled for the VoIP access category. If UAPSD is disabled for this access category, this value is 0. ▪ VI: If 1, UAPSD is enabled for the Video access category. If UAPSD is disabled for this access category, this value is 0. ▪ BK: If 1, UAPSD is enabled for the Background access category. If UAPSD is disabled for this access category, this value is 0. ▪ BE: If 1, UAPSD is enabled for the Best Effort access category. If UAPSD is disabled for this access category, this value is 0. ▪ Max SP: The maximum service period is the number of frame sent per trigger packet. This value is value can be 0, 2, 4 or 8. ▪ Q Len: The number of frames currently queued for the client, from 0 to 16 frames.
Tx_Pkts	Number of packets transmitted from the AP to the client.
Rx_Pkts	Number of packets the AP received from the client.
PS_Qlen	Number of packets in the power-save queue length.
Tx_Retries	Number of packets that the AP had to resend to the client due to an initial transmission failure.
Tx_rate	Rate at which last packet was sent to the client (in Mbps).
Rx_rate	Rate at which last packet was received from the client (in Mbps).
Last_ACK_SNR	SNR of the last acknowledge packet sent by the client.
Last_Rx_SNR	SNR of the last data packet received from the client.
TX_Chains	The first digit in this value indicates the number of transmission chains on the radio currently in use and the number in brackets shows which of the chains are active.

Parameter	Description
	<p>The current status of each chain is indicated by a single-digit binary number; 1 if the chain is active, and 0 if it is inactive. In the example output above (2 [0x5]), two chains are active; chain one and chain three.</p> <ul style="list-style-type: none"> ▪ chain one: 1 (active) ▪ chain two: 0 (inactive) ▪ chain three: 1 (active) <p>In the example above, the chain would generate the value 101, which translates to the hexadecimal number 5. If all three chain were active, it would generate the value 111, (the hexadecimal number 7), and would appear in the CLI output as 3 [0x7].</p>
Tx_timestamp	Date and time the last packet was sent to the client.
Rx_timestamp	Date and time the last packet was received from the client.
MFP status	Client is 802.11W capable/802.11W is enabled on radio.
Idle Time	Number of seconds elapsed since a packet was received from the client.
Client Health	<p>Shows the health of the client and the AP radio in the format <client_health>/<AP-health>. These values report the quality of link between the client and the radio,</p> <p>An AP's client health is the efficiency at which that AP transmits downstream traffic to a particular client. This value is determined by comparing the amount of time the AP spends transmitting data to a client to the amount of time that would be required under ideal conditions, that is, at the maximum Rx rate supported by client, with no data retries. A client health metric of 100% means the actual airtime the AP spends transmitting data is equal to the ideal amount of time required to send data to the client. A client health metric of 50% means the AP is taking twice as long as is ideal, or is sending one extra transmission to that client for every packet. A metric of 25% means the AP is taking four times longer than the ideal transmission time, or sending 3 extra transmissions to that client for every packet.</p>

Related Commands

Command	Description
rf arm-profile	This command enables ClientMatch.
show ap arm client-match neighbors	This command displays the BSSID of other APs seen by clients in the select AP's RF neighborhood.

Command	Description
<u>show ap arm virtual-beacon-report</u>	This command displays the virtual beacon report for an AP with a specific IP or MAC address.
<u>show ap arm client-match unsupported</u>	This command displays a list of clients that failed to be steered to a more optimal AP, and the reason the initial steering request was triggered.
<u>show ap arm client-match summary</u>	This command shows the history of AP association changes triggered by the client match feature.
<u>show ap arm client-match history</u>	This command shows the history of AP association changes triggered by the client match feature.
<u>show ap arm client-match restriction-table</u>	This command displays the list of clients that ClientMatch has restricted from the specified AP.

show ap debug client-trace

```
show ap client-trace
  {ap-name <ap-name>|clients|ip-addr <ip-addr>}|ip6-addr <ip6-addr>}<mac>
```

Description

This command shows the counts of different types of management data frames traced from a client MAC address. You must issue the command only under the guidance of Aruba technical support. This command is supported on 100 Series, 120 Series, and 130 Series access points only.

Parameter	Description
ap-name <ap-name>	Shows counts for an AP with a specific name.
clients	Shows all registered clients in the AP.
ip-addr <ip-addr>	Shows counts for an AP with a specific IP address by entering an IP address in the dotted-decimal format.
ip6-addr <ip6-addr>	Shows counts for an AP with a specific IPv6 address by entering an IPv6 address in the dotted-decimal format.
<mac>	MAC address of the client.

Example

The following example shows an AP model that does not support the `show ap debug client-trace` command.

```
(host) #show ap debug client-trace ap-name ap-205
The AP platform does not support the command
```

Related Commands

Command	Description
ap debug client-trace start	Use this command to trace management packets from a client MAC address.
ap debug client-trace stop	Use this command to stop tracing management packets from a client MAC address.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show ap debug client-trace clients

```
show ap debug client-trace clients {ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows debug client trace for all registered clients in an AP.

Parameter	Description
ap-name <ap-name>	Shows debug client trace for all registered clients in an AP for specified AP name.
ip-addr <ip-addr>	Shows debug client trace for all registered clients in an AP for specified IP address.
ip6-addr <ip6-addr>	Shows debug client trace for all registered clients in an AP for specified IPv6 address.

Example

The following example shows an AP named ap-205 does not support the show ap debug client-trace clients command:

```
(host) [mynode] #show ap debug client-trace clients ap-name ap-205  
The AP platform do not support the command
```

Related Commands

Command	Description
ap deploy-profile	This command applies the AP deployment policy to the default AP group, and/or to the list of AP MAC addresses included in the UAP blacklist table, and/or to the specified IP address range. The AP deployment policy redirects the applicable APs to the Instant discovery process, ensuring that the APs run only in controller-less mode.

show ap debug counters

```
show ap debug counters {ap-name <ap-name>|bssid <bssid>|group <group>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command shows AP reboot/bootstrap counters and crash information for an individual AP or AP group, or all APs referenced on the controller.

Parameter	Description
ap-name <ap-name>	Shows debug counters for an AP with a specified name.
bssid <bssid>	Shows debug counters for a specific BSSID. The BSSID is usually the AP's MAC address.
group <group>	Shows debug counters for an AP group.
ip-addr <ip-addr>	Shows debug counters for an AP with a specified IP address by entering an IP address in the dotted-decimal format.
ip6-addr <ip6-addr>	Shows debug counters for an AP with a specified IPv6 address by entering an IPv6 address in the dotted-decimal format.

Example

The output of this command shows how many times each AP has rebooted (a hard boot) or bootstrapped (a soft boot), the number of configuration changes sent and acknowledged by that AP, and whether or not the AP rebooted due to a kernel crash.

In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual CLI, it will appear in a single, long table.

```
(host) #show ap debug counters group corp1
AP Counters
-----
Name   Group  IP Address  Configs Sent  Configs Acked  AP Boots Sent
-----
AL1    corp1  10.6.1.209  1597          1597           0
AL10   corp1  10.6.1.198  165           165            0
AL12   corp1  10.6.1.200  195           195            0
AL15   corp1  10.6.1.197  1580          1580           0
AL16   corp1  10.6.1.199  73            73             0
AL19   corp1  10.6.1.212  8             8              0

AP Boots Acked  Bootstraps (Total)  Reboots  Crash
-----
0             1                (1)      0      N
```

```

0          2          (2)          1          Y
0          1          (1)          0          N
0          1          (1)          0          N
0          1          (1)          0          N
0          1          (1)          0          N
Total APs :6

```

The output of this command includes the following information:

Column	Description
Name	Name of the AP.
Group	Name of the AP's group.
IP Address	IP address of the AP.
Configs sent	Number of times configuration changes have been sent to the AP.
Configs Acked	Number of times that the AP has acknowledged receiving a configuration change.
AP Boots Sent	Number of times reboot requests have been sent to the AP.
AP Boots Acked	Number of times that the AP has acknowledged receiving a reboot request.
Bootstraps	Number of times the AP bootstrapped since AP reboot. Bootstraps are also known as "soft" restarts.
Total Bootstraps	Total number of times the AP bootstrapped since AP image upgrade.
Reboots	Number of times power to the AP cycled off and then on again since image upgrade. Reboots also known as "hard" restarts.
Crash	Indicates whether or not the AP was rebooted due to a kernel crash. Use show ap debug crash-info command to view the crash signature.

show ap debug crash-info

```
show ap debug crash-info {ap-name <ap-name>|ip-addr <ip-addr>
ip6-addr <ip6-addr>}
```

Description

This command shows crash log information (if it exists) for an individual AP. The stored information is cleared from the flash after the AP reboots.

Parameter	Description
ap-name <ap-name>	Shows crash information for an AP with a specified name.
ip-addr <ip-addr>	Shows crash information for an AP with a specified IP address by entering an IP address in the dotted-decimal format.
ip6-addr <ip6-addr>	Shows crash information for an AP with a specified IPv6 address by entering an IPv6 address in the dotted-decimal format.

Example

The output of this command shows a partial sample crash log information for an AP named **MyAP**:

```
(host) #show ap debug crash-info ap-name MyAP

show ap debug crypto

```
show ap debug crypto
  ap-name <ap-name>
  detail {[ap-name <ap-name>]|[ip-addr <ip-addr>]|[ip6-addr <ip6-addr>]}
  history {[ap-name <ap-name>]|[ip-addr <ip-addr>]|[ip6-addr <ip6-addr>]}
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command shows the debug crypto logs for an AP.

Parameter	Description
ap-name <ap-name>	Shows debug crypto logs for the specified AP name.
detail	Shows detailed debug crypto logs for: <ul style="list-style-type: none">■ ap-name■ ip-addr■ ip6-addr
history	Shows historical debug crypto logs for: <ul style="list-style-type: none">■ ap-name■ ip-addr■ ip6-addr
ip-addr <ip-addr>	Shows debug crypto logs for the specified IP address of an AP.
ip6-addr <ip6-addr>	Shows debug crypto logs for the specified IPv6 address of an AP.

Example

The example shows the AP debug crypto logs of an AP named **MyAP**:

```
(host) [mynode] #show ap debug crypto ap-name MyAP

show ap debug datapath

```
show ap debug datapath {ap-group <ap-group>|ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

Show datapath tunnel parameters of an AP or AP group.

Parameter	Description
ap-group <ap-group>	Shows data path information for a specific AP group.
ap-name <ap-name>	Shows data path information for an AP with a specific name.
bssid <bssid>	Shows data path information for a specific BSSID. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Shows data path information for an AP with a specific IP address by entering an IP address in the dotted-decimal format.
ip6-addr <ip6-addr>	Shows data path information for an AP with a specific IPv6 address by entering an IP address in the dotted-decimal format.

Example

The output of the following command shows datapath tunnel parameters for an AP with the IP address 192.0.2.32.

```
(host) #show ap debug datapath ip-addr 192.0.2.32

Datapath Parameters Table
-----
essid   encr-alg      client-vlan-id  tunnel-id  gre-type  deny-bcast  num-clients
-----
-----
guest   Open          63              0x10f6    0x8300    disable     0
voip    WPA2 8021X AES 66              0x1103    0x8310    disable     7
corp    WPA2 PSK AES  66              0x10f1    0x8320    disable     0
guest   Open          63              0x10f7    0x8200    disable     1
wpa2    WPA2 8021X AES 65              0x10be    0x8210    enable      15
```

The output of this command includes the following information:

Column	Description
ESSID	The ESSID is a unique name that identifies a wireless network
encr-alg	Encryption algorithm used by the network
client-vlan-id	ID of the network VLAN
tunnel-id	Identification number of the AP's tunnel.
gre-type	GRE tunnel type.
deny-bcast	If enabled , the AP will respond to broadcast probe requests. If disabled , the AP will not respond to these requests.
num-clients	Number of clients currently using the network.

The output of the following command shows datapath tunnel parameters for an AP with the IPv6 address 11:12:11:11::2.

```
(host) #show ap debug datapath ip6-addr 11:12:11:11::2
Datapath Parameters Table

show ap debug dot11r efficiency

```
show ap debug dot11r efficiency <client-mac>
```

Description

This command displays all the r1 keys that are stored in an AP and the hit/miss rate of r1 keys cached on an AP before a Fast BSS Transition roaming.

Parameter	Description
efficiency <client-mac>	Shows the hit/miss rate of r1 keys cached on an AP before a Fast BSS Transition roaming for the specified client MAC address.

Examples

Use this command to view all the r1 keys that are stored in an AP.

```
(host) #show ap debug dot11r efficiency
Fast Roaming R1 Key Efficiency
-----
Client MAC          Hit (%)  Miss (%)

show ap debug dot11r state

```
show ap debug dot11r state [ap-name <ap-name> | ip-addr <ip-addr>]
```

Description

This command displays all the r1 keys that are stored in an AP.

Parameter	Description
ap-name <ap-name>	Shows debugging information for a specific AP.
ip-addr <ip-addr>	Shows debugging information for an AP with a specific IP address by entering its IP address in the dotted-decimal format.

Examples

Use this command to view all the r1 keys that are stored in an AP. You can filter the output based on the AP name or IP address.

```
(host) #show ap debug dot11r state ap-name MAcage-105-GL

Stored R1 Keys

show ap debug driver-log

```
show ap debug driver-log {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip-addr>}
```

Description

This command shows an AP's driver logs. Use this command to review configuration changes made since the AP was last reset.

Parameter	Description
ap-name <ap-name>	Shows log information for an AP with a specific name.
bssid <bssid>	Shows log information for a specific BSSID. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Shows log information for an AP with a specific IP address by entering an IP address in the dotted-decimal format.
ip6-addr <ip-addr>	Shows log information for an AP with a specific IPv6 address by entering an IPv6 address in the dotted-decimal format.

Example

The following example shows an AP's driver logs:

```
(host) #show ap debug driver-log ap-name AP_205_26

The command output shows information only applicable for the specified AP. The output of the previous command is only a representative information of the likely output.

The output parameters in the command output (NSS State) are explained in the following table:

Column	Description
NSS LAG	Corresponds to the AP lag. This means that link aggregation is enabled on the Ethernet ports in NSS. This is only for the IP acceleration rule, so that NSS can expect packets coming in on both ports to match an acceleration rule. It is not necessarily for LACP. It is applicable for active-standby as well.
NSS Jumbo	Meant for the AP ports. This corresponds to the NSS phy layer setting to receive jumbo (9 KB) frames.
LMS GRE redi	Indicates GRE tunnel in NSS. In the output, the if_num value (for example, if_num 24) is the NSS interface number for a specific GRE tunnel.
LMS GRE rule	Refers to the IP-GRE acceleration rule for client traffic from and to the controller.
Standby GRE redir	Same as the LMS GRE redir, but corresponds to that of the standby controller.
Standby GRE rule	Same as the LMS GRE rule, but corresponds to that for the standby controller.
<p>NOTE: NSS refers to the network subsystem. It is a flow acceleration chipset from Qualcomm used in AP-315, and AP-325 access points. The hardware has Ethernet, IP, and GRE flow acceleration modules, IP fragmentation/reassembly, IPsec encap/decap. NSS also has the corresponding driver software. Most of these functions were performed by the software in previous AP models.</p>

show ap debug gsm-counters

```
show ap debug gsm-counters
  verbose
```

Description

Displays the GSM counters of an AP or AP group.

Parameter	Description
verbose	Shows the event statistics in a tabular format.

Example

The output of the following command shows gsm counters of an AP:

```
(host) (config) #show ap debug gsm-counters verbose
STM GSM Counters
-----
Name                                     Value
----                                     -
AP Publish Events                       15

show ap debug hotspot statistics bssid

```
show ap debug hotspot statistics bssid <bssid_string>
```

Description

This command shows the statistics of ANQP/H2QP information.

Parameter	Description
bssid <bssid_string>	Shows statistics of ANQP/H2QP information for the specified BSSID.

Example

The following example shows the statistics of ANQP/H2QP information for the BSSID 00:1a:1e:aa:bb:cc:

```
(host) [mynode] #show ap debug hotspot statistics bssid 00:1a:1e:aa:bb:cc
```

show ap debug iot-sniffer

```
show ap debug iot sniffer {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip-addr>}  
radio {all|<radio-mac-addr>}
```

Description

This command shows IoT sniffer information on the AP.

Parameter	Description
ap-name <ap-name>	Shows IoT information for an AP with a specific name.
ip-addr <ip-addr>	Shows IoT information for an AP with a specific IP address.
ip6-addr <ip-addr>	Shows IoT information for an AP with a specific IPv6 address.
radio	Shows IoT information of the radio in an AP
all	Shows IoT information of all radios in an AP.
<radio-mac-addr>	Shows IoT information of a specific radio in an AP.

Example

The following example displays an AP's ipc forwarding statistics.

```
(host) [mynode] #show ap debug iot-sniffer ap-name AP-215 radio all

show ap debug lacp

```
show ap debug lacp {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr<ip6-addr>}
```

Description

This command shows the number of GRE packets sent and received on the two Ethernet ports. Use this command to know if LACP is active on an AP from the number of GRE packets sent and received on the two Ethernet ports. If a GRE striping IP address is configured in the **ap-lacp-striping-ap** profile, the output of this command displays the GRE striping IP address.

Parameter	Description
ap-name <ap-name>	Shows LACP information for an AP with a specific name.
bssid <bssid>	Shows LACP information for a specific BSSID. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Shows LACP information for an AP with a specific IPv4 address.
ip6-addr <ip6-addr>	Shows LACP information for an AP with a specific IPv6 address.

Example 1

The following example displays that the wireless GRE packets are being sent and received on different wired ports of the AP for the 5GHz and 2.4GHz bands, and is only applicable to 220 Series and 270 Series. It also shows that the interfaces eth0 and eth1 are part of the link aggregation group (LAG):

```
show ap debug lacp ap-name 3ap225

AP LACP GRE Striping IP: 10.65.30.50
AP LACP Status
-----
Link Status  LACP Rate  Num Ports  Actor Key  Partner Key  Partner MAC
-----
Up           slow       2          17         2           00:0b:86:61:7a:58
Slave/Member Interface Status
-----
Slave/Member I/f Name  Permanent MAC Addr  Link Status  Member of LAG  Link
Fail Count
-----
---
eth0                  6c:f3:7f:c6:72:82  Up           Yes            0
eth1                  6c:f3:7f:c6:72:83  Up           Yes            1
```

GRE Radio Traffic Received on Enet Ports

```
-----  
Radio Num  Enet 0 Rx Count  Enet 1 Rx Count  
-----  
0          5048          0

show ap debug lldp counters

```
show ap debug lldp counters {ap-name <ap-name>} {ip-addr <ip-addr>} {ip6-addr <ip6-addr>} [interface <port-string>]
```

Description

This command shows LLDP statistics of an AP.

Parameter	Description
ap-name <ap-name>	Shows LLDP statistics of an AP for specified AP name.
ip-addr <ip-addr>	Shows LLDP statistics of an AP for specified IP address.
ip6-addr <ip6-addr>	Shows LLDP statistics of an AP for specified IPv6 address.
interface <port-string>	Shows LLDP statistics for specified interface of an AP.

Example

The following example shows radio scanning of an AP named ap-205:

```
(host) [mynode] #show ap debug lldp counters ap-name ap-205

LLDP Counters
-----
Interface  Received  Unknown TLVs  Malformed  Overflow  Transmitted
-----
bond0      49937     0              0           0         49914
```

show ap debug lldp neighbors

```
show ap debug lldp neighbors {ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>} [interface <port-string> [detail]]
```

Description

This command shows LLDP peer information of an AP.

Parameter	Description
ap-name <ap-name>	Shows LLDP peer information of an AP for specified AP name.
ip-addr <ip-addr>	Shows LLDP peer information of an AP for specified IP address.
ip6-addr <ip6-addr>	Shows LLDP peer information of an AP for specified IPv6 address.
interface <port-string> [detail]	Shows LLDP peer information for specified interface of an AP. Detail parameter shows additional LLDP peer information.

Example

The following example shows LLDP peer information of an AP named ap-205:

```
(host) [mynode] #show ap debug lldp neighbors ap-name ap-205

Capability codes: (R)Router, (B)Bridge, (A)Access Point, (P)Phone, (O)Other
LLDP Neighbor Information
-----
Interface  Neighbor ID          Capabilities  Remote Interface  Expiry-Time
(SeCs)    -----
-----
bond0      00:0b:86:96:fe:f7   B:R          GE0/0/2           91

show ap debug log-config

```
show ap debug log-config {ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows AP log configuration.

Parameter	Description
ap-name <ap-name>	Shows AP log configuration for specified AP name.
ip-addr <ip-addr>	Shows AP log configuration for specified IP address.
ip6-addr <ip6-addr>	Shows AP log configuration for specified IPv6 address.

Example

The following example shows an AP named ap-205 is not registered with managed device:

```
(host) [mynode] #show ap debug log-config ap-name ap-205
AP is not registered with this switch
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show ap debug multizone

```
show ap debug multizone
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command shows the MultiZone configured for an AP.

Parameter	Description
ap-name <ap-name>	Name of AP.
ip-addr <ip-addr>	IP Address of AP.
ip6-addr <ip6-addr>	IPv6 address of AP.

Example

The following example shows the MultiZone configured for a particular AP:

```
(host) [mynode] (config) #show ap debug multizone ap-name RFCage05_AP214_2_
C_6_7031

Multizone Table
-----
Zone  Configured IP      Serving IP          Max Vaps Allowed  Nodes  Flags
----  -
0     10.16.84.10        10.16.84.10        13 (0~12)         1      2
1     2008::abc:90:90::4 2008::abc:90:90::4 3 (0-2)            1      V
Flags: C = Cluster; L = Limited nodes; N = Nodes in other zones; 2 = Using
IKE version 2; M = Image mismatch; V = IP version mismatch
Number of datazones:1
```

Command History

Release	Modification
ArubaOS 8.4.0.0	The output of the <code>show ap debug multizone</code> command was modified to include V flags that indicate the IP version mismatch between primary zone and data zone configuration.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode in managed devices.

show ap debug mu-status

```
show ap debug mu-status
  ap-name <ap-name>
  bssid <bssid>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command shows detailed MU status of the clients associated with an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	SA status data for an AP with a specific name.
bssid <bssid>	SA status data for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	SA status data for an AP with a specific IP address by entering an IP address in the dotted-decimal format.
ip6-addr <ip6-addr>	SA status data for an AP with a specific IPv6 address by entering an IPv6 address in the dotted-decimal format.

show ap debug openflow

```
show ap debug openflow
  flows {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
  state {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} detail
```

Description

This command shows the OpenFlow protocol.

Parameter	Description
<code>flows {ap-name <ap-name> ip-addr <ip-addr> ip6-addr <ip6-addr>}</code>	Shows OpenFlow protocol flows filtered by specified AP name, IP address of an AP, or IPv6 address of an IP.
<code>state {ap-name <ap-name> ip-addr <ip-addr> ip6-addr <ip6-addr>} detail</code>	Shows basic or detailed OpenFlow protocol state filtered by specified AP name, IP address of an AP, or IPv6 address of an AP.

Example

Access the CLI and use the following command to show basic OpenFlow protocol state of AP **test**:

```
(host) [mynode] #show ap debug openflow state ap-name test

Controller IP: 0.0.0.0, port:0, State: Init, Last Up:Thu Jan  1 05:30:00
1970, Last down:Thu Jan  1 05:30:00 1970
Openflow Interface List
  IF MAC:9c:1c:12:c0:95:c8, port_no:8453, name:bond0, oflow_index:0
OpenFlow MAC Bridge List
OpenFlow Dynamic Tunnel List
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show ap debug port status

```
show ap debug port status {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command shows the status of the AP's wired ports.

Parameter	Description
ap-name <ap-name>	Name of the AP.
bssid <bssid>	BSSID of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.

Examples

The output of the command displays the wired port status of an AP named **LocalAP1**. In this example, the output is divided into multiple sections to fit better on the pages of this document. In the actual CLI, it appears in a single long table.

```
(host) [mynode] #show ap debug port status ap-name LocalAP1

AP "LocalAP1" Port Status

show ap debug power-table

```
show ap debug power-table {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}  
{radio <radio id>}
```

Description

Displays the following information for a specific radio:

- Power limit table based on regulatory powers, user configured power, and override powers.
- Board limit table.
- A combination of all the above fields to calculate the actual transmit power of the packets.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows power table for an AP with a specific name.
ip-addr <ip-addr>	Shows power table for an AP with a specific IP address.
ip6-addr <ip6-addr>	Shows power table for an AP with a specific IPv6 address.
radio <radio id>	Radio ID (0, 1, or 2).

Examples

The output of this command displays power table from an AP-225.

```
(host) [mynode] #show ap debug power-table ap-name AP-225 radio 0
```

Command History

Release	Modification
ArubaOS 8.10.0.0	The command output was modified to include <code>Flash EIRP Limit</code> parameter for 6 GHz bands.
ArubaOS 8.6.0.0	Radio ID 2 was introduced for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

show ap debug radar-logs

```
show ap debug radar-logs
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command shows the latest four RADAR event logs from the AP. This command is useful for debugging false radar detection related issues.

This command is applicable for APs running the Broadcom chipset.

Parameter	Description
ap-name <ap-name>	Displays RADAR logs for an AP with a specific name.
ip-addr <ip-addr>	Displays RADAR logs for an AP with a specific IP address.
ip6-addr <ip6-addr>	Displays RADAR logs for an AP with a specific IPv6 address.

Example

The output of this command displays RADAR logs from an AP-225.

```
(host) #show ap debug radar-logs ap-name AP-225

show ap debug radio-diag-log status

```
show ap debug radio-diag-log <status>
```

Description

This command displays the current diagnostic logging status of an AP.

Parameter	Description
status	Displays the current diagnostic logging status.

Example

The following command displays the output after the `ap debug radio-diag-log start` command is executed:

```
(host) [mynode] #show ap debug radio-diag-log status ap-name ap555
Status: Started. radio-diag-log is in progress
Log size: 3145728 bytes
grep pattern: -e WMI -e WAL
Error: None
Dump server: 10.100.225.27
Transfer mode: scp
```

Related Commands

Command	Description
ap debug radio-diag-log	This command collects WLAN firmware diagnostic logs to facilitate firmware debugging.

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
AP-534, AP-535, AP-555 access points	Base operating system.	Enable mode on Mobility Conductor.

show ap debug radio-event-log status

```
show ap debug radio-event-log status {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

Show information about the radio event information captured in packet log files.

Parameter	Description
ap-name <ap-name>	Shows log information for an AP with a specific name.
ip-addr <ip-addr>	Shows log information for an AP with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows log information for an AP with a specific IPv6 address by entering its IPv6 address.

Example

```
Radio Event Logs
-----
Radio Index  Radio's Bssid      Radio's Band  Event Type  Log File Size
Status
-----
---
0           00:24:6c:bd:65:b0  80211a       N/A         N/A
start
1           00:24:6c:bd:65:a0  80211g       N/A         N/A
stop
```

The output of this command includes the following information:

Parameter	Description
radio Index	Index number of the AP radio (0 or 1).
Radio's BSSID	BSSID of the AP radio. This is typically the AP radio's MAC address.
Radio's Band	Band used by the AP radio.
Event Type	Type of events recorded. By default, all supported event types are recorded. <ul style="list-style-type: none">■ N/A: The default event type setting, which captures all

Parameter	Description
	<p>supported types of radio events.</p> <ul style="list-style-type: none"> ■ ani Adaptive Noise Immunity control events ■ rcfind: Transmission (Tx) control event ■ rcupdate: Transmission (Tx) rate update event ■ rx: Received (Rx) status register event ■ text: Text record event ■ tx: Transmission (Tx) control and Tx status register event
Log File Size	Size of the log file. A value of N/A indicates that the packet log feature uses the default log file size of 3145728 bytes (3MB).
Status	Shows if packet log capture was started or stopped on the AP radio.

Related Commands

Command	Description
ap debug radio-event-log	This command starts and stops packet log capture of radio events for debugging purposes, and sends a log file of the events to a dump server when logging stops.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug radio-info

```
show ap debug radio-info
  ap-name <ap-name> radio <radio id>
  ip-addr <ip-addr> radio <radio id>
  ip6-addr <ip6-addr> radio <radio id>
```

Description

This command shows the Wi-Fi radio debug logs from the AP driver.

This command is applicable for 200 Series, 210 Series, 220 Series, 270 Series, and 550 Series access points.

Parameter	Description
ap-name <ap-name>	Shows Wi-Fi radio debug logs for an AP with a specific name.
ip-addr <ip-addr>	Shows Wi-Fi radio debug logs for an AP with a specific IP address.
ip6-addr <ip6-addr>	Shows Wi-Fi radio debug logs for an AP with a specific IPv6 address.
radio <radio id>	Radio ID (0, 1, or 2)

Example

The output of this command displays the log information about Wi-Fi radio 0 for an AP-225:

```
(host) #show ap debug radio-info ap-name AP-225 radio 0

Radio Info Script
-----
aruba_dbg_radio_info_0 Start time: Fri Mar 27 14:33:21 IST 2015

show ap debug radio-registers

```
show ap debug radio-registers {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>} {radio 0|1|2}
```

Description

This command allows you to view radio register changes.

Parameter	Description
ap-name <ap-name>	Name of the AP for which you want to view register changes.
ip-addr <ip-addr>	IPv4 address of the AP for which you want to view register changes.
ip6-addr <ip6-addr>	IPv6 address of the AP for which you want to view register changes.
radio 0 1 2	Shows information for the specified radio on the AP.

This command displays radio register changes made under the supervision of Aruba technical support.

Command History

Release	Modification
ArubaOS 8.6.0.0	Radio 2 radio ID was introduced for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug radio-stats

```
show ap debug radio-stats {ap-name <ap-name>|ip-addr <ip-addr>} radio {0|1|2}
[advanced]
```

Description

This command shows aggregate radio debug statistics of an AP.

Parameter	Description
ap-name <ap-name>	Shows log information for an AP with a specific name.
ip-addr <ip-addr>	Shows log information for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	IPv6 address of the Access Point.
radio {0 1 2}	Specify the ID number of the radio for which you want to view statistics.
advanced	Include this parameter to display additional radio statistics.

Example

The output of this command displays general statistics for the radio, as well as statistics for transmitted and received frames.

```
(host) #show ap debug radio-stats ap-name AP12 radio 1

```

If you include the **advanced** option at the end of the `show ap debug radio-stats` command, the output of this command will include all the following parameters, as well as additional information for the SNR, frame counts, channel busy times, and data bytes for transmitted and received packets. If you omit the **advanced** option, the output will include less information, and the data will be displayed in a different order. The following table describes the output of this command when the **advanced** option is included.

Parameter	Description
Total Radio Resets	Total number of times the radio reset.
Resets Beacon Fail	Number of times the radio reset due to beacon failure.
BB check positives	Number of times the radio checked for a base-band hang condition
Resets BeacQ Stuck	An AP's radio typically sends a beacon every 100 milliseconds. If beacons are not sent at a regular interval or the radio experiences excessive noise, the beacon queue will reset. This parameter indicates the number of queue resets.
Resets Fatal Intr	Number of time the radio was reset because the AP hardware was unresponsive.
Resets RX Overrun	The number of radio resets due to Receive FIFO overruns.
Resets RF Gain	Number of radio resets due to gain changes.
Resets MTU Change	Number of times the radio reset due to a change in the Maximum Transmission Unit (MTU) value.
Resets TX Timeouts	Number of radio resets due to transmission timeouts (the radio doesn't transmit a signal within the required time frame.)
POE-Related Resets	If the radio power profile drops, an AP may not be able to support three transmit chains, and may drop to two chains only. This parameter displays the number of resets due to this type of power change.
External Reset	Number of times the AP has been reset because it was unplugged or its reset button was pressed.
PCI Fatal Intr Reset	Radio reset due to PCI fatal interrupt received from radio chip.
Chaimask Reset	Radio reset when new chain mask is configured.
TX stat Reset	Radio reset caused by inconsistent state of hardware transmit queue.
TX Power Changes	Number of times the radio's transmission power changed.
Channel Changes	Number of times the radio's channel changed.
Radio Band Changes	Number of time the radio's band changed.

Parameter	Description
Current Noise Floor	The residual background noise detected by an AP. Noise seen by an AP is reported as -dBm. Therefore, a noise floor of -100 dBm is smaller (lower) than a noise floor of -50 dBm. For most environments, the noise floor should be no greater than -80 dBm. Anything larger may indicate an interference problem which is drowning out good signals (data) in background noise.
Dummy NF pkts on home channel	Number of noise floor readings on the home channel.
Dummy NF pkts on scan channel	Number of noise floor readings on the scan channel.
Avail TX Buffers	An AP has a set number of buffers which it can use to buffer frames for non-responsive power save clients. The total number of buffer frames depends upon the AP model type.
11g Protection	This parameter shows whether 802.11g protection has been enabled or disabled.
Last TX Antenna	This parameter indicates whether the last frame transmitted was sent on antenna 1 or antenna 0. This parameter can be useful for troubleshooting external antennas.
Last RX Antenna	This parameter indicates whether the last frame received was via antenna 1 or antenna 0. This parameter can be useful for troubleshooting external antennas.
Scan Requests	Total number of scan requests received by the AP.
Scan Rejects	Total number of scan rejected by the AP.
Scan Rejects (Misc 1)	Number of scan rejects due to pending transmissions.
Load aware Scan Rejects	Load aware ARM preserves network resources during periods of high traffic by temporarily halting scanning if the load for the AP gets too high. The <code>load aware Scan Rejects</code> parameter shows the number of times the AP has rejected a scan because of the load aware scan feature.

Parameter	Description
PS aware Scan Rejects	If the ARM power-save aware scan feature is enabled, the AP will not scan a different channel if it has one or more clients and is in power save mode. The <code>ps aware Scan Rejects</code> parameter shows the number of times the AP has rejected a scan because of the power-save aware scan feature.
EAP Scan Rejects	If you enable the EAP-aware scanning feature in the AP's ARM profile, the AP will not attempt to scan a different channel if the Extensible Authentication Protocol over LAN (EAPOL) exchange is in progress with a client. This parameter shows the number of times the AP has rejected a scan because of the EAP aware scanning feature.
Voice aware Scan Rejects	If you enable the VoIP Aware Scan feature in the AP's ARM profile, the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This <code>Voice aware scan Rejects</code> parameter shows the number of times the AP has rejected a scan because of the Voip aware scan feature.
Video aware Scan Rejects	If you enable the Video Aware Scan feature in the AP's ARM profile, the AP will not attempt to scan a different channel if one of its clients has an active video session. This <code>Video aware scan Rejects</code> parameter shows the number of times the AP has rejected a scan because of the Video aware scan feature.
UAPSD Scan Rejects	Number of times the scan was rejected due to UAPSD-related transmissions.
Post radar related scan Rejects	Number of times the scan was rejected due to recent radar detection.
CABQ traffic Scan Rejects	Number of times the scan was rejected due to pending multicast transmissions.
Radio Reset Scan Rejects	Number of times the scan was rejected due to a recent radio reset.
Queue Drain Scan Rejects	This legacy statistic has been deprecated, and will not increment.
Scan Success	Number of successful scans. To view scan details, use the command show ap arm scan-times .

Parameter	Description
Scan Deferred	Number of times the scan was deferred due to pending beacon transmissions on the home channel.
EIRP	The value of this parameter is the transmission power level (in dBm) + the antenna gain value.
MAX EIRP	The max EIRP depends on AP capability and the regulatory domain constraint for the channel of operation. For example, in the US, Channels 36-48 have max EIRP of 23dBm
Dummy<number>	For internal use only.
UAPSD Flush STA Wake	Number of times a client wakes from power-save mode and flushes the UAPSD queue.
UAPSD SP Set	The number of unique UAPSD Scheduled Period is started in response to UAPSD trigger frames.
UAPSD Dup Trig	The number of times duplicate UAPSD trigger frames are received (i.e., retried UAPSD triggers that were received by the AP more than once).
UAPSD Recv frame for TX	The number of frames received for transmission over the air interface using UAPSD
UAPSD Ageout Drain	The number of time UAPSD queue is drained (i.e. frames are dropped) due to ageout.
UAPSD TX proc comp	The number of UAPSD frames that were successfully transmitted
UAPSD SP In prog	The number of times a trigger frame was received while a Scheduled Period (SP) was already in progress based on an earlier trigger frame.
UAPSD QOS NULL TX	The number of times the AP had to respond with a QoS Null Data frame in response to a UAPSD trigger because AP did not have Data frame queued for that client
UAPSD TX HW Queued	The number of frames (Data and Null Data) that were transferred to the radio HW for transmission, in response to UAPSD triggers.
UAPSD SP Reset	The number of times the UAPSD Scheduled Period (SP) in progress is reset or canceled.
Tx Time perct @ beacon intvl	Percentage of time spent transmitting Wi-Fi frames since the last beacon.

Parameter	Description
Tx Frames Rcvd	Number of transmitted frames that were received.
Tx Bcast Frames Rcvd	Number of transmitted broadcast frames that were received.
Tx Frames Dropped	Number of transmitted frames that were dropped.
Tx Bcast Frames Dropped	Number of transmitted broadcast frames that were dropped.
Tx Frames Transmitted	Number of frames successfully transmitted.
Tx Bytes Rcvd	Number of transmitted bytes received.
Tx Bytes Transmitted	Number of transmitted bytes
Tx Time Frames Rcvd	Number of times transmitted frames were received.
Tx Time Frames Dropped	Number of times transmitted frames were dropped.
Tx Time Frames Transmitted	Number of times frames were transmitted.
Tx PS Unicast	Number of power save unicast frames
Tx DTIM Broadcast	Number of broadcast frames with DTIM values.
Tx Success With Retry	Number of frames that were successfully transmitted after being retried.
Tx Multiple retries	Number of frames that were successfully transmitted after being retried multiple times.
Tx Mgmt Frames	Number of management frames transmitted.
Tx Mgmt Frames (PPS)	Rate of retransmitted frames, in packets per second.
Tx Beacons Transmitted	Number of beacons transmitted.
Tx Beacons Transmitted (PPS)	Rate of transmitted beacons, in packets per second.
Tx Probe Responses	Number of transmitted probe responses.
Tx Probe Responses (PPS)	Rate of transmitted probe responses, in packets per second.
Tx Data Transmitted Retried	Number of retried data frames.

Parameter	Description
Tx Data Transmitted	Number of transmitted data frames.
Tx Data Frames	Number of transmitted data frames.
Tx Broadcast Data Frames In	Number of broadcast data frames received by the AP from wired interface to be transmitted in the air.
Tx Data Bytes Transmitted	Total data bytes received by an AP from its wired interface to be transmitted over the air.
Tx Data Bytes	Total data bytes transmitted by the AP over the air.
Tx Time Data Transmitted	Total time on spent successfully transmitting frames (including the retried frames).
Tx Time BC/MC Data	Total time spent transmitting broadcast/multicast frames.
Tx Time Data dropped	Total time spent transmitting dropped frames.
Tx Time Data	Total time spent sending frames received for transmission, including the frames that were dropped after retrying.
Tx Broadcast Data Frames Sent	Broadcast data frames transmitted by the AP.
Tx Broadcast Data Frames Sent (PPS)	Rate of broadcast data frames transmitted by the AP, in packets per second.
Tx Multicast Data Frames	Multicast data frames transmitted by the AP.
Tx Multicast Data Frames (PPS)	Rate of multicast data frames transmitted by the AP, in packets per second.
Tx DMO Multicast	The number of multicast frames transmitted as multicast without converting to unicast.
Tx DMO Invalid	The number of multicast frames which should have been converted but were not as due to invalid format. (This value is typically normally 0.)
Tx DMO Converted	The number of multicast frames received as multicast which were then converted to unicast one or more times. This counter increments once per multicast frame.

Parameter	Description
Tx DMO Replicated	The number of frames transmitted as unicast frames. For each multicast frame the counter is incremented by the number of replications for that frame. (The number of replications is the number of clients associated to the BSSID, VLAN or group receiving these frames).
Tx DMO Dropped	The number of frames dropped as conversion was not consistent with state on the AP. (This value is typically normally 0.)
Tx DMO No Client	Number of times no client was found for an association-ID indicated by the frame. (This value is typically normally 0.)
Tx DMO No BSSID	Number of times the BSSID indicated by the frame was not found. (This value is typically normally 0.)
Tx Unicast Data Frames	Number of transmitted unicast data frames
Tx RTS Success	Number of Ready To Send (RTS) frames successfully transmitted.
Tx RTS Failed	Number of Ready To Send (RTS) frames that were not successfully transmitted
Tx CTS Frames	Number of Clear-to-Send (CTS) frames transmitted.
Tx CTS Frames (PPS)	Rate of CTS frames sent, in packets per second. (This parameter does not include CTS frames send in response to RTS).
Tx Powersave Queue Timeouts	Number of transmit frames discarded from the power save queue because the frames aged out
Tx Dropped After Retry	Number of frames dropped after an attempted retry.
Tx Dropped No Buffer	Number of frames dropped because the AP's buffer was full.
Tx Missed ACKs	Number of retries triggered because an acknowledgment was not received.
Tx Failed Beacons	Number of times a radio failed to transmit a beacon at the scheduled interval (100ms).
Tx Multi-Beacon Fail	Number of times multiple consecutive beacons failed to transmit.
Tx Long Preamble	Number of frames sent with a long preamble.
Tx Short Preamble	Number of frames sent with a short preamble.

Parameter	Description
Tx Beacon Interrupts	Number of broadcast beacons that were interrupted.
TX Interrupts	Number of transmission interrupts.
Tx FIFO Underrun	The number of transmitted FIFO overruns.
Tx Allocated Desc	Number of allocated transmit descriptors.
Tx Freed Desc	Number of freed transmit descriptors.
Tx EAPOL Frames	Number of EAPOL frames transmitted
TX STBC Frames	Number of transmitted frames with Space-time block coding (STBC) enabled.
TX LDPC Frames	Number of transmitted frames with Low Density Parity Check (LDPC) enabled.
Tx AGGR Good	Number of aggregated frames successfully transmitted.
Tx AGGR Unaggr	Number of non-aggregate frames transmitted due to unavailability of additional frames for aggregation at the time of transmission.
Tx data <number> Mbps	Number of frames transmitted at the specified rate (in Mbps).
Tx <number> Mbps [Long]	Number of frames with a long preamble transmitted at the specified rate.
Tx <number> Mbps [Short]	Number of frames with a short preamble transmitted at the specified rate.
Tx HT <number> Mbps	Number of high-throughput frames transmitted at the specified rate.
Tx WMM [category]	<p>Number of Wi-Fi Multimedia (WMM) packets transmitted for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <ul style="list-style-type: none"> ▪ Tx WMM [BE]: Best Effort ▪ Tx WMM [BK]: Background ▪ Tx WMM [VO]: VoIP ▪ Tx WMM [VI]: Video

Parameter	Description
Tx WMM [category] dropped	Number of dropped Wi-Fi Multimedia (WMM) packets in the following access categories . If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command. <ul style="list-style-type: none"> ▪ Tx WMM [BE]: Best Effort ▪ Tx WMM [BK]: Background ▪ Tx WMM [VO]: VoIP ▪ Tx WMM [VI]: Video
Tx UAPSD OverflowDrop	Number of packets dropped due to Unscheduled Automatic Power Save Delivery (U-APSD) overflow.
TX Timeouts	Number of transmission timeouts
Lost Carrier Events	Number of carrier sense timeouts.
Tx HT40 Hang Detected	Parameter deprecated.
Tx HT40 Hang Stuck	Parameter deprecated.
Tx HT40 Hang Possible	Parameter deprecated.
Tx HT40 Dfs IMM WAR	Number of times the HT 40 RX Clear Hang immunity workaround was employed.
Tx HT40 Dfs HT20 WAR	Number of times the HT 20 RX Clear Hang immunity workaround was employed.
Tx MAC/BB Hang Stuck	Number of times a workaround was employed for potential beacons stuck due to MAC or base-band stuck conditions.
Tx Mgmt Bytes	Total management frame bytes transmitted.
Tx Beacons Bytes	Total number of Beacon frame bytes transmitted.
Tx Data Frames/Bytes 24 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (12-24)
Tx Data Frames/Bytes 36 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (24-36)
Tx Data Frames/Bytes 54 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (36-54)
Tx Data Frames/Bytes 72 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (54-72)
Tx Data Frames/Bytes 108 Mbps (Mon)	Total number of data frames and corresponding bytes transmitted at rate (72-108)

Parameter	Description
Tx Data Frames MCS 0	Total number of data frames transmitted at rate of MCS 0
Tx Data Frames MCS 1	Total number of data frames transmitted at rate of MCS 1
Tx Data Frames MCS 2	Total number of data frames transmitted at rate of MCS 2
Tx Data Frames MCS 3	Total number of data frames transmitted at rate of MCS 3
Tx Data Frames MCS 4	Total number of data frames transmitted at rate of MCS 4
Tx Data Frames MCS 5	Total number of data frames transmitted at rate of MCS 5
Tx Data Frames MCS 6	Total number of data frames transmitted at rate of MCS 6
Tx Data Frames MCS 7	Total number of data frames transmitted at rate of MCS 7
Tx Data Frames MCS 8	Total number of data frames transmitted at rate of MCS 8
Tx Data Frames MCS 9	Total number of data frames transmitted at rate of MCS 9
Tx Data Frames Legacy	Total number of data frames transmitted at legacy rate
Tx Data Frames MCS	Total number of data frames transmitted at MCS rate
Tx Data Frames NSS1	Total number of data frames transmitted 1 spacial stream
Tx Data Frames NSS2	Total number of data frames transmitted with 2 spacial stream
Tx Data Frames NSS3	Total number of data frames transmitted with 3 spacial stream
Tx Data Frames Short-GI (HALF)	Total number of data frames transmitted with short GI
Tx Data Frames Long-GI (FULL)	Total number of data frames transmitted with long GI
Tx Data Frames BW20	Total number of data frames transmitted at 20 Mhz

Parameter	Description
Tx Data Frames BW40	Total number of data frames transmitted at 40 Mhz
Tx Data Frames BW80	Total number of data frames transmitted at 80 Mhz
Tx Data Frames BW160	Total number of data frames transmitted at 160 Mhz
Tx Data Frames Dropped	Number of transmitted data frames that were dropped.
Tx AMSDU pkt count	Total number of AMSDU bytes transmitted.
Rx Last SNR	The last recorded signal-to-noise ratio.
Rx Last SNR CTL0	The signal-to-noise ratio for the last received data packet on the primary (control) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR CTL1	The signal-to-noise ratio for the last received data packet on the secondary (control) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR CTL2	The signal-to-noise ratio for the last received data packet on the secondary (control) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR EXT0	Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR EXT1	Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last SNR EXT2	Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last ACK SNR EXT0	Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 0. This parameter is only displayed for APs operating in 40 Mhz mode.

Parameter	Description
Rx Last ACK SNR EXT1	Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 1. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Last ACK SNR EXT2	Signal-to-noise ratio for the last received ACK packet on the secondary (extension) channel 2. This parameter is only displayed for APs operating in 40 Mhz mode.
Rx Frames Received	Number of frames received.
Rx Good Frames	Number of frames received with no errors.
Rx Bad Frames	Number of bad or error frames received.
Rx Total Data Frames Recvd	Total number of data frames received.
Rx Total Mgmt Frames Recvd	Total number of management frames received.
Rx Total Control Frames Recvd	Total number of control frames received.
Rx Total Bytes Recvd	Total number of bytes received.
Rx Total Data Bytes Recvd	Total number of data bytes received.
Rx Total RTS Frames Recvd	Total number of Ready-To-Send (RTS) frames received.
Zx Total CTS Frames Recvd	Number of Clear-to-Send (CTS) frames received.
Rx Total ACK Frames	Number of acknowledgment frames received.
Rx Total Beacons Received	Number of beacons received.
Rx Total Probe Requests	Number of probe requests received.
Rx Total Probe Responses	Number of probe responses received.
Rx retry frames	Number of retried frames received.
Channel busy 1s	The percentage of time the radio channel was busy in the last 1 second.
Channel busy 4s	The percentage of time the radio channel was busy in the last 4 seconds.
Channel busy 64s	The percentage of time the radio channel was busy in the last 64 seconds.
Ch Busy perct @ beacon intvl	Percentage of time the channel was busy over the last 30 beacon intervals.

Parameter	Description
Rx Time perct @ beacon intvl	Percentage of time the AP was receiving data over the last 30 beacon intervals.
Rx Discarded Events	Number of non-802.11 events that were detected and discarded during normal operation.
Rx ARM Scan Frames	Number of scan frames sent for the adaptive radio management (ARM) feature.
Rx Data Frames	Number of data frames received.
Rx Data Frames (PPS)	Rate at which data frames were received, in packets per second.
Rx Data Bytes	Number of data bytes received.
Rx Time Data	Total time spent on frames successfully received.
Rx Duplicate Frames	Number of duplicate frames received.
Rx Broadcast Data Frames	Number of broadcast frames received.
Rx Multicast Data Frames	Number of multicast frames received.
Rx Unicast Data Frames	Number of unicast frames received.
Rx Null Data Frames	Number of null data frames received.
Rx Mgmt Frames	Number of management frames received.
Rx Mgmt Frames (PPS)	Rate at which management frames were received, in packets per second.
Rx Control Frames	Number of control frames received.
Rx Control Frames (PPS)	Rate at which control frames were received, in packets per second.
Rx Frames To Me	Number of frames received that are addressed to the specified BSSID.
Rx Bytes To Me	Number of bytes received that are addressed to the specified BSSID.
Rx Time To Me	Total time spent receiving frames sent to a specified BSSID.
Rx Broadcast Frames	Number of broadcast frames received.
Rx Probe Requests	Number of Probe requests received.

Parameter	Description
Rx Probe Requests (PPS)	Rate at which probe requests were received, in packets per second.
Rx RTS Frames	Ready To Send (RTS) frames received. These frames are sent when a computer has data to transmit.
Rx RTS Frames (PPS)	Rate at which RTS frames were received, in packets per second.
Rx CTS Frames	Clear To Send (CTS) frames received. This type of frame are used to verify that a client is ready to receive information.
Rx CTS Frames (PPS)	Rate at which CTS frames were received, in packets per second.
RX PS Poll Frames	Power-Save Poll (PS-Poll) frames received. When a client exits a power-saving mode, it transmits a PS-Poll frame to the AP to retrieve any frames buffered while it was in power-saving mode.
RX CRC Errors	Cyclic Redundancy Check (CRC) is a data sequence that is sent with a frame to help verify if all the data received correctly. Possible CRC error causes include: <ul style="list-style-type: none"> ▪ Hardware malfunction ▪ Loose or unconnected cables ▪ RF interference, such as overlapping access point coverage on a channel or interfering 2.4-GHz signals from devices like microwave ovens ▪ and wireless handset phones
RX PLCP Errors	Physical Layer Convergence Protocol (PLCP) errors.
Rx Frames Dropped	Number of received frames that were dropped.
Rx PHY Events	The number of Physical Layer Events, that are not 802.11 packets, detected by radio as part of its normal receive operation.
Rx RADAR Events	Number of times an AP detects a radar signature. Aruba APs are DFS-compliant detects a radar signature, it will change its channel.
RX Interrupts	The number of receive interrupts received by the CPU from the radio.
RX Overrun	The number of Receive FIFO overruns.
Rx undecryptable	Number of non-decryptable frames received.

Parameter	Description
RX STBC Frames	Number of received frames with STBC enabled.
RX LDPC Frames	Number of received frames with LDPC enabled.
Rx data <number> Mbps	Data packets received at the specified rate (in Mbps).
Rx <number> Mbps	Packets received at the specified rate (in Mbps).
Rx data <number> Mbps	Packets received at the specified rate (in Mbps).
Rx HT <number> Mbps	Number of high-throughput packets received at the specified rate.
Rx WMM [BE]	<p>Number of Wifi Multimedia (WMM) packets received for the following access categories. If the AP has not transmitted packets in a category type, this data row will not appear in the output of the command.</p> <ul style="list-style-type: none"> ▪ Rx WMM [BE]: Best Effort ▪ Rx WMM [BK]: Background ▪ Rx WMM [VO]: VoIP ▪ Rx WMM [VI]: Video
RX bad length	Number of frames received with incorrect length.
Rx Null Src MAC	Number of received frames with source MAC address as NULL.
Rx Managment Frames Dropped	Number of received management frames that were dropped.
Rx Data Frames Dropped	Number of received data frames that were dropped.
SNR from CTL0	Signal-to-noise ratio (SNR) on chain 0.
Throttle drops	Number of received frames dropped by AP due to throttling when AP is under high load.
Stop all but Mgmt	Number of data frames dropped because radar was detected on a channel. An AP is allowed to send management frames only and must drop all other frames when radar is detected on a channel.

Command History

Release	Modification
ArubaOS 8.6.0.0	Radio 2 radio ID was introduced for AP-555 access points.
ArubaOS 8.3.0.0	The output of this command was modified to include MCS bucket mapping information channel width, number of spatial streams, and guard interval information of 802.11ac APs.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug received-config

```
show ap debug received-config
  ap-name <ap-name> [essid <essid>]
  bssid <bssid> [essid <essid>]
  ip-addr <ip-addr> [essid <essid>]
  ip6-addr <ip6-addr> [essid <essid>]
```

Description

This command shows the configuration the AP downloaded from the managed device.

Parameter	Description
ap-name <ap-name>	Shows log information for an AP with a specific name.
bssid <bssid>	Shows log information for a specific BSSID. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Shows log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows log information for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.

Example

The output of this command displays configuration information for each interface. The example below shows only part of the output for this command. Additional parameters not shown in this example are described in the table below.

```
(host) #show ap debug received-config ap-name AP12

Downloaded Config for WIFI 0

```

The output of this command includes the following information:

Parameter	Description
BSSID	The BSSID of the AP.
LMS IP	The LMS IP is the IP address of the managed device used by the AP for client data processing.
Master/Conductor IP	IP address of Mobility Conductor, the central configuration and management point for all managed devices.
Mode	Shows the operating modes for the AP. <ul style="list-style-type: none"> ap-mode: Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN. am-mode: Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.
QBSS Probe Response	Quality-of-service BSS (QBSS).
Native VLAN ID	The ID number of the Native VLAN.
SAP MTU	The Maximum Transmission Unit (MTU) for the GRE tunnel.
Heartbeat DSCP	DSCP value for the heartbeat traffic between the AP and the managed device.

Parameter	Description
High throughput enable (radio)	Shows if high-throughput (802.11n) features on tare enabled or disabled on the radio.
Channel	Shows the channel number for the AP's 802.11a/802.11n physical layer.
Beacon Period	Shows the time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.
Transmit Power	Shows the current transmission power level.
Advertise TPC Capability	If enabled, the AP will advertise its Transmit Power Control (TPC) capability.
Enable CSA	Displays whether or not the AP has enabled channel switch announcements (CSAs) for 802.11h.
CSA Count	Number of channel switch announcements that must be sent before the AP will switch to a new channel.
Management Frame Throttle interval	Average interval that rate limiting management frames are sent from this radio, in seconds. If this column displays a zero (0), rate limiting is disabled for this AP.
Management Frame Throttle Limit	Maximum number of management frames that can come from this radio in each throttle interval.
Active Scan	Displays whether or not the active scan feature is enabled. This option elicits more information from nearby APs, but also creates additional management traffic on the network. Active Scan is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Aruba Support.
VoIP Aware Scan	Shows if VoIP aware scanning is enabled or disabled. If you use voice handsets in the WLAN, VoIP Aware Scan should be enabled in the ARM profile so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that Scanning is also enabled.
Power Save Aware Scan	Shows if the power save aware scan is enabled or disabled. If enabled, the AP will not scan a different channel if it has one or more clients and is in power save mode.

Parameter	Description
Load aware Scan Threshold	The Load Aware Scan Threshold is the traffic throughput level an AP must reach before it stops scanning. Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high.
40 MHz intolerance	The specified setting allows ARM to determine if 40 MHz mode of operation is allowed on the 5 GHz or 2.4 GHz frequency band only, on both frequency bands, or on neither frequency band.
Honor 40 MHz intolerance	Shows if 40 MHz intolerance is enabled or disabled. If enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.
Legacy station workaround	Shows if interoperability for misbehaving legacy stations is enabled or disabled.
Country Code	Display the country code for the AP. The country code specifies allowed channels for that country.
ESSID	An Extended Service Set Identifier (ESSID), for the AP.
Encryption	Encryption type used on this AP.
WPA2 Pre-Auth	802.11x settings are enabled or disabled .
DTIM Interval	Number of beacons that should elapse before an AP sends beacon broadcasts for power save clients.
802.11a Basic Rates	Minimum data rate required for a client to associate with the AP. For an 802.11a radio, this value can be 6, 12 and 24 802.11 data rates. 802.11b/g radios will report a value of 1 and 2 802.11 data rates.
802.11a Transmit Rates	802.11 data rate at which the AP will transmit data to its clients. This value can be 6-54 for 802.11a radios, and 1-54 for 802.11b/g radios.
Station Ageout Time	Number of seconds a station may be idle before it is deauthorized from an AP.
Max Transmit Attempts	maximum number of times the AP will attempt to retransmit data.
RTS Threshold	The minimum packet size at which the AP will issue a request-to-send (RTS) before sending the packet.

Parameter	Description
Max Associations	The maximum number of clients allowed to associated with the AP
Wireless Multimedia (WMM)	Shows if Wireless Multimedia (WMM) is enabled or disabled for this AP. WMM provides prioritization of specific traffic relative to other traffic in the network.
WMM TSPEC Min Inactivity Interval	Displays the minimum inactivity time-out threshold of WMM traffic for this AP.
DSCP mapping for WMM voice AC	Displays the DSCP value used to map WMM voice traffic.
DSCP mapping for WMM video AC	Displays the DSCP value used to map WMM video traffic.
DSCP mapping for WMM best-effort AC	Displays the DSCP value used to map WMM best-effort traffic
DSCP mapping for WMM background AC	Displays the DSCP value used to map WMM background traffic.
Hide SSID	Shows if the feature to hide a SSID name in beacon frames is enabled or disabled .
Deny_Broadcast Probes	When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID.
Local Probe Response	Shows if local probe response is enabled or disabled on the AP. If this option is enabled, the AP is responsible for sending 802.11 probe responses to wireless clients' probe requests. If this option is disabled, then the managed device sends the 802.11 probe responses
Disable Probe Retry	Shows if the AP has enabled or disabled MAC-level retries for probe response frames. By default this parameter is enabled, which mean that MAC level retries for probe response frames is disabled.
Maximum Transmit Failures	Display the maximum number of transmission failures allowed before the client gives up.

Parameter	Description
BC/MC Rate Optimization	Shows if the AP has enabled or disabled scanning of all active stations currently associated to that AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate.
High throughput enable (SSID)	Shows if the AP has enabled or disabled the use of its high-throughput SSID in 40 MHz mode.
40 MHz channel usage	Determines if this high-throughput SSID allows high-throughput (802.11n) stations to associate.
MPDU Aggregation	Shows if the AP has enabled or disabled MAC protocol data unit (MPDU) aggregation.
Max transmitted A-MPDU size	Shows the maximum size, in bytes, of an A-MPDU that can be sent on the AP's high-throughput SSID.
Max received A-MPDU size	Shows the maximum size, in bytes, of an Aggregated-MAC Packet Data Unit (A-MPDU) that can be received on the AP's high-throughput SSID.
Min MPDU start spacing	Displays the minimum time between the start of adjacent MDPU within an aggregate MPDU, in microseconds.
Supported MCS set	Comma-separated list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this high-throughput SSID.
Short guard interval in 40 MHz mode	Shows if the AP has enabled or disabled use of short guard interval in 40 MHz mode of operation.
VLAN	VLAN ID used by the SSID.
Forward mode	Shows the current forward mode (bridge, split-tunnel, or tunnel) for the virtual AP. This parameter controls whether 802.11 frames are tunneled to the managed device using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the managed device, and Internet access remains local). Only 802.1X authentication is supported when configuring bridge or split tunnel mode.
Band Steering	Shows if band-steering has been enabled or disabled for a virtual AP.

Parameter	Description
	<p>ARM's band steering feature encourages dual-band capable clients to stay on the 5 GHz band on dual-band APs. This frees up resources on the 2.4 GHz band for single band clients like VoIP phones.</p> <p>Band steering reduces co-channel interference and increases available bandwidth for dual-band clients, because there are more channels on the 5 GHz band than on the 2.4 GHz band. Dual-band 802.11n-capable clients may see even greater bandwidth improvements, because the band steering feature will automatically select between 40 MHz or 20 MHz channels in 802.11n networks. This feature is disabled by default, and must be enabled in a Virtual AP profile.</p>

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .
ArubaOS 8.6.0.0	The output will display details of Radio 2 for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug received-log-config

```
show ap debug received-log-config {ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows log of configuration received by an AP.

Parameter	Description
ap-name <ap-name>	Shows log of configuration received by specified AP name.
ip-addr <ip-addr>	Shows log of configuration received by an AP for specified IP address.
ip6-addr <ip6-addr>	Shows log of configuration received by an AP for specified IPv6 address.

Example

The following example shows log of configuration received by an AP named ap-205:

```
(host) [mynode] #show ap debug received-log-config ap-name ap-205

AP log level config
-----
Facility  Level      Sub Category  Level
-----  -
arm       warnings
network   warnings
security  warnings   ids           warnings
security  warnings   ids-ap        warnings
system    warnings
user      warnings
wireless  warnings
Log level config version :1

AP debug level config
-----
Facility  Level  Debug value  Sub Category
-----  -
Debug log config version :1
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap debug received-reg-table

```
show ap debug received-reg-table {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows downloaded regulatory table for an AP.

Parameter	Description
ap-name <ap-name>	Shows downloaded regulatory table for a specified AP name.
bssid <bssid>	Shows downloaded regulatory table for a specified BSSID.
ip-addr <ip-addr>	Shows downloaded regulatory table for a specified IP address.
ip6-addr <ip6-addr>	Shows downloaded regulatory table for a specified IPv6 address.

Example

The following example shows downloaded regulatory table for an AP named ap-205 (For versions prior to ArubaOS 8.9.0.0).

```
(host) [mynode] #show ap debug received-reg-table ap-name ap-205

Command History

Release	Modification
ArubaOS 8.9.0.0	The 6g value was introduced under <code>PHY Type</code> output parameter for Wi-Fi 6E APs.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap debug scan-settings

```
show ap debug scan-settings {ap-name <ap-name>}{{ip-addr <ip-addr>}}{ip6-addr <ip6-addr>}
```

Description

This command shows radio scanning of an AP.

Parameter	Description
ap-name <ap-name>	Shows radio scanning of an AP for specified AP name.
ip-addr <ip-addr>	Shows radio scanning of an AP for specified IP address.
ip6-addr <ip6-addr>	Shows radio scanning of an AP for specified IPv6 address.

Example

The following example shows radio scanning of an AP named ap-205:

```
(host) [mynode] #show ap debug scan-settings ap-name ap-205
```

```
Radios Scan-setting
```

```
-----  
Radio Index  Status  
-----
```

```
0             Enable  
1             Enable
```

The following example shows radio scanning of an AP-555 ,

```
(host) #show ap debug scan-settings ap-name AP555-0
```

```
Radios Scan-setting
```

```
-----  
Radio Index  Status  
-----
```

```
0             Enable  
1             Enable  
2             Enable
```

Command History

Release	Modification
ArubaOS 8.6.0.0	The output will display the status of Radio 2 for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap debug ses-esl-log

```
show ap debug ses-esl-log {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command displays the SES-Imagatog's ESL server logs for an AP.

Parameter	Description
ap-name <ap-name>	The name of the AP.
ip-addr <ip-addr>	The IP address of the AP.
ip6-addr <ip6-addr>	The IPv6 address of the AP.

Examples

The following example shows the SES-Imagatog's ESL server logs for an AP:

```
(Host) *[mynode] (config) #show ap debug ses-esl-log ap-name AP32x_03

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
AP-303H, 300 Series access points, 310 Series access points, 320 Series access points, 330 Series access points, 340 Series access points, and 510 Series access points	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug shaping-table

```
show ap debug shaping-table {ap-name <ap-name>|ip-addr <ip-addr>}
```

Description

This command shows shaping information for clients associated to an AP.

Parameter	Description
ap-name <ap-name>	Show shaping table information for a specific AP.
ip-addr <ip-addr>	Show shaping table information for a specific AP IP address by entering its IP address in dotted-decimal format.

Example

The following command shows the shaping table of an AP named ap22.

```
(host) #show ap debug shaping-table ap-name ap22

3	0	0	0	0	0	0	0	0	0

The output of this command includes the following information:

Column	Description
pktin	Number of packets received by the AP.
pktout	Number of packets sent by the AP.
pktdrop	Number of packets dropped by the AP.
pktqd	Number of packets queued.
drop	Number of CCK (802.11b) and OFDM (802.11a/g) packets dropped.
Numcl	Number of CCK (802.11b) and OFDM (802.11a/g) packets dropped.
TotCl	Total number of clients associated with the AP
Bwmgmt	This data column displays a 1 if the bandwidth management feature has been enabled. Otherwise, it displays a 0.
idx	Association ID.
tokens	This value represents the credits the station has to transmit tokens.
last-t	Number of tokens that were allocated to the station last time token allocation algorithm ran.
in	Number of packets received.
out	Number of packets sent.
drop	Number of dropped packets.
q	Number of queued packets
tx-t	Total time spent transmitting data.
rx-t	Total time spent receiving data.
al-t	Total time allocated for transmitting data to this station.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug spanning-tree

Syntax

```
show ap debug spanning-tree {ap-group <ap-group>|ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

Description

This command shows an AP's spanning tree statistics.

Parameter	Description
ap-name <ap-name>	Show log information for an AP with a specific name.
bssid <bssid>	Show log information for a specific BSSID. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show log information for an AP with a specific IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show log information for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.

Example

The following command shows the AP debug spanning tree state.

```
(host) [mynode] #show ap debug spanning-tree
```

Command History

show ap debug sta-msg-stats

Syntax

```
show ap debug sta-msg-stats {[ap-name <ap-name>] [bssid <bssid>]}
```

Description

This command shows AP-STM to STM message statistics.

Parameter	Description
ap-name <ap-name>	Shows AP-STM to STM message statistics for specified AP name.
bssid <bssid>	Shows AP-STM to STM message statistics for specified BSSID.

Example

The following example shows AP-STM to STM message statistics for BSSID d8:c7:c8:38:fc:f5:

```
(host) [mynode] #show ap debug sta-msg-stats bssid d8:c7:c8:38:fc:f5

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap debug switching

Syntax

```
show ap debug switching {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command shows an AP's switching statistics.

Parameter	Description
ap-name <ap-name>	Name of the access point.
ip-addr <ip-addr>	IP address of the access point.
ip6-addr <ip6-addr>	IPv6 address of the access point.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap debug system-status

```
show ap debug system-status
  ap-name <ap-name>
  bssid <bssid>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command shows detailed system status information for an AP.

Parameter	Description
ap-name <ap-name>	Show system status data for an AP with a specific name.
bssid <bssid>	Show system status data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the AP's MAC address.
ip-addr <ip-addr>	Show system status data for an AP with a specific IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show system status data for an AP with a specific IPv6 address by entering an IPv6 address in dotted-decimal format.

Issue this command under the guidance of Aruba technical support to troubleshoot network issues. The output of this command displays the following types of information (if it exists) for the selected AP:

■ Bootstrap information	■ Per-radio statistics	■ Ethernet duplex/speed settings
■ Descriptor Usage	■ Encryption statistics	■ Tunnel heartbeat stats
■ Interface counters	■ AP uptime	■ Boot version
■ MTU discovery	■ Memory usage	■ LMS information
■ ARP cache	■ Kernel slab statistics	■ Power status
■ Route table	■ Interrupts	■ CPU type
■ Interface Information	■ Crash Information	■ CPU usage statistics
■ System Status Script	■ Radio profile name	■ Dual 5 GHz mode
■ NSS CPU Usage		

Power Status

The following lines under power status indicate the power status of the AP:

- **Operational State** indicates the current state of the AP, that is, as seen with the power light on the AP. **Operational State** may be different from **Current HW State** as a result of LLDP negotiation.
- **Current HW State** indicates the result from POE negotiation in hardware.
- **LLDP Negotiated POE Power** indicates the LLDP negotiated power.

The following parameters are included in the output of this command, and can help troubleshoot problems on an AP or wireless network.

Parameter	Description
The Failed column in the Descriptor Usage section	This parameter can tell you if the AP is dropping packets.
Interface Information table	This parameter can tell you if the Ethernet network is working properly. This table should not show an excessive number of errors.
AP Uptime table	Low values in this table can indicate problems with the wired network, or with the AP itself.
Tunnel Heartbeat table	This table can indicate the health of the underlying wired network.
Rebootstrap Information table / Reboot Information table	A large number of reboots can mean that the AP has hardware problems.

Example

The following example shows the NSS CPU usage of an AP:

```
(host) [mynode] #show ap debug system-status ap-name XXX
NSS CPU usage
-----
CPU Utilization:
Note: Averaged over 1 second
Core 0:
Min      Avg      Max
3%       5%       8%
```

Command History

Release	Modification
ArubaOS 8.8.0.0	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ■ A new output parameter, <code>NSS CPU Usage</code> was introduced. The NSS CPU usage will be displayed only for AP-534, AP-535, and AP-555 access points. ■ The output of the command was modified to display Ethernet related details.
ArubaOS 8.0.0.0	Command introduced.

show ap debug trace-addr

show ap debug trace-addr

Description

This command shows MAC addresses in the trace buffer. Use this command to troubleshoot wireless clients that are being traced for 802.11 communication.

Examples

The output of the command shows the **Trace List** table. If no wireless clients are being traced, this table will be empty.

```
(host) #show ap debug trace-addr

Trace List
-----
MAC Address
-----
00:1a:1e:c5:ca:b4
00:1a:1e:c5:d6:46
00:1a:1e:c5:d7:40
00:1a:1e:c5:d7:64
00:1a:1e:c5:d9:56
00:1a:1e:c5:d9:b0

  log
```

Description

This command shows debugging information of USB devices managed on an AP.

Parameter	Description
ap-name <ap-name>	Show debugging information of USB devices managed on an AP that is specified by the AP name.
ip-addr <ip-addr>	Show debugging information of USB devices managed on an AP that is specified by the IP address.
ip6-addr <ip6-addr>	Show debugging information of USB devices managed on an AP that is specified by the IPv6 address.
log	Show debugging log of USB devices managed by an AP that is specified by AP name, IP address, or IPv6 address.
device all	Show device debugging information of all USB devices managed by an AP.
module all	Show module debugging information of USB devices managed by an AP.
plugin {all detail <plugin-name>}	Show plugin debugging information of USB devices managed by an AP.
rule all	Show rule debugging information of USB devices managed by an AP.
subscriber {all detail <service-type>}	Show subscriber debugging information of USB devices managed by an AP.

Example

The following command shows the debug statistics of USB devices managed on an AP that is specified by AP name:

```
(host) [mynode] #show ap debug usb-device-mgmt ap-name 325 device all

USB Device Table
-----
Device ID  Manufacturer  Product  Serial Number  Version  VendorID

show ap deploy-profile

```
show ap deploy-profile
```

Description

This command shows if the AP deploy profile is enabled or not. It also displays if the policy is applied on default AP group, status of the blacklist/denylist policy and the complete list of IPv4 and IPv6 address ranges to which the AP deployment policy is applied.

Example

The following command displays the status of the AP deploy profile and various configurations applied on the profile:

```
(host) [mynode] #show ap deploy-profile

Profile enabled: no
Apply to default ap group: no
Blacklist/Denylistenabled: yes

AP deploy policy IP range Table
-----
Starting IP   Ending IP
-----
1.1.1.1      1.1.1.10

AP deploy policy IPv6 range Table
-----
Starting IP   Ending IP
-----
::3          ::5
2016::1      2016::10
2016::15     2016::15
```

Related Commands

Command	Description
ap deploy-profile	This command applies the AP deployment policy to the default AP group, and/or to the list of AP MAC addresses included in the UAP blacklist/denylist table, and/or to the specified IP address range. The AP deployment policy redirects the applicable APs to the Instant discovery process, ensuring that the APs run only in controller-less mode.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.2.0.0	Command introduced.

show ap details

```
show ap details [advanced] {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>|wired-mac <wired-mac>}
```

Description

This command shows the detailed provisioning parameters, hardware, and operating information for a specific AP.

Parameter	Description
advanced	Shows additional information of specified AP. Include the following additional data in the output of this command: <ul style="list-style-type: none">■ Switch message counts■ AP group information■ Virtual AP operating information
ap-name <ap-name>	Show data for a specific AP by entering the name of the AP for which you want to display information.
ip-addr <ip-addr>	Show data for an AP with the specified IP address.
ip6-addr <ip6-addr>	Show data for an AP with the specified IPv6 address.
wired-mac <wired-mac>	Show mac address of an AP.

Examples

The following example shows part of the output for the command `show ap details advanced ap-name <ap-name>`.

```
(host)[node] #show ap details advanced ap-name ap-205
AP "ap-205" Basic Information
-----
Item                Value

Primary Channel     36       Configuration
80MHz Channel Group 36-48    Configuration
EIRP                10.0     Configuration
Fast recovery start 2017-03-09 11:57:56
Fast recovery end  2017-03-09 11:58:00
Fast recovery    1

```

The output of this command includes the following information:

Parameter	Description
AP IP Address	IP address of the AP
LMS IP Address	The IP address of the local management switch (LMS)—the Aruba controller which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network.
Group	Name of the AP's AP group.
Location Name	Location of the AP.
Status	Current status of the AP, either Up or Down .
Up time	Number of hours, minutes and seconds since the last controller reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .
AP Type	AP model
Serial #	Serial number for the AP
Wired MAC address	MAC address of the wired interface.
Radio 0 BSSID	Basic Service Set Identifier (BSSID) of the AP's radio 0. This is usually the radio's MAC address.
Radio 1 BSSID	Basic Service Set Identifier (BSSID) of the AP's radio 1. This is usually the radio's MAC address.
Radio 2 BSSID	Basic Service Set Identifier (BSSID) of the AP's radio 2. This is usually the radio's MAC address.

Parameter	Description
Enet 1 MAC address	MAC address of the Ethernet1 port of AP.
Enet 3 MAC address	MAC address of the Ethernet3 port of AP.
Enet 4 MAC address	MAC address of the Ethernet4 port of AP.
Enet 5 MAC address	MAC address of the Ethernet5 port of AP.
Enet 6 MAC address	MAC address of the Ethernet6 port of AP.
Enet 7 MAC address	MAC address of the Ethernet7 port of AP.
Fast recovery start	Start date and time of the AP Fast Recovery process.
Fast recovery end	End date and time of the AP Fast Recovery process.
Fast Recovery	Number of Fast Recoveries that happened in the AP.

The following example shows the output of the `show ap details advanced ip-addr <ip-addr>` command, where a controller ages out an AP:

```
(host)[node] #show ap details advanced ip-addr 10.3.90.17
AP "9c:1c:12:c0:86:5a" Basic Information

show ap enet-link-profile

```
show ap enet-link-profile [<profile>]
```

Description

This command shows a list of all Ethernet Link profiles. Include a profile name to display details for the specified Ethernet Link Profile, or omit the <profile> parameter to display a list of all Ethernet Link profiles.

Example

This command shows the speed of the Ethernet interface and the current duplex mode for the Ethernet Link profile "default":

```
(host) [mynode] #show ap enet-link-profile default

AP Ethernet Link profile "default"
-----
Parameter  Value
-----  -
Speed                auto
Duplex              auto
802.3az (EEE)       Disabled
802.3bz             Yes
Power over Ethernet Disabled
The output of this command includes the following parameters:
```

Parameter	Description
Speed	The speed of the Ethernet interface. This value can be either 10 Mbps , 100 Mbps , 1000Mbps (1 Gbps), or auto (auto-negotiated).
Duplex	The duplex mode of the AP's Ethernet interface. This value can be either full , half , or auto (auto-negotiated).
802.3az	This displays if the support for the 802.3az Energy Efficient Ethernet (EEE) standard is enabled.
802.3bz	This displays if the support for IEEE 802.3bz standard is enabled.
Power Over Ethernet	This displays if the physical port is Power over Ethernet (PoE) enabled.

Related Commands

Command	Description
ap enet-link-profile	This command configures an AP Ethernet link profile.

Command History

Release	Modification
ArubaOS 8.3.0.0	A new row 802.3bz displays if the standard is enabled or disabled for an AP.
ArubaOS 8.0.0.0	Command introduced.

show ap essid

```
show ap essid
```

Description

This command shows an ESSID summary for the controller, including the number of APs and clients associated with each ESSID.

Examples

The following example shows statistics for four configured ESSIDs (For versions prior to ArubaOS 8.9.0.0).

```
(host) [mynode] #show ap essid
ESSID Summary
-----
ESSID          APs  Clients  VLAN(s)  Encryption
-----
vocera  21   0         66      WPA2 PSK AES
voip    23   52        66,64   WPA2 8021X AES
guest   49   6         63      Open
wpa2    26   88        65,64   WPA2 8021X AES
Num ESSID:4
```

The following example shows statistics for two configured ESSIDs (ArubaOS 8.9.0.0 or later versions).

```
(host) [mynode] #show ap essid
ESSID Summary
-----
ESSID          APs  MBSSID Tx BSS  Clients  VLAN(s)  Encryption
-----
8@hbm-635-psk  1    1             0         1         WPA3 SAE AES
9@hbm-535-rtp  1    0             0         1         WPA2 PSK AES
Num ESSID:2
```

The output of this command includes the following information:

Parameter	Description
ESSID	An Extended Service Set Identifier (ESSID) is the identifying name of an 802.11 wireless network.
APs	Number of APs associated with the ESSID.

Parameter	Description
MBSSID Tx BSS (ArubaOS 8.9.0.0 or later versions)	Number of APs that have the specific BSSID or virtual AP as the transmitted virtual AP.
Clients	Number of clients associated with the ESSID.
VLAN(s)	VLAN IDs of the VLANs for the ESSID.
Encryption	The layer-2 authentication and encryption used on this ESSID to protect access and ensure the privacy of the data transmitted to and from the network.

Related Commands

show ap est-status

```
show ap est-status ap-name <ap-name> | ip-addr <ip-addr>
```

Description

Shows the EST status of APs terminated on the controller.

Parameter	Description
ap-name <ap-name>	Show data for a specific AP by entering the name of the AP for which you want to display information.
ip-addr <ip-addr>	Show data for an AP with the specified IP address.

Example

The following example shows the EST status of an AP:

```
(host) [mynode] #show ap est-status ap-name b4:5d:50:ce:18:36
Server Host           : 10.15.100.142
Server Port          : 443
EST Status            : Enabled
Enrollment Status    : Enrolled
Local time           : Thu Sep 12 15:25:49 2019 IST
Cert beg             : Thu Sep 12 15:05:59 2019 IST
Cert end             : Sat Oct 12 15:35:59 2019 IST
Reenrollment due     : Sat Oct 5 03:28:29 2019 IST
Reenrolled           : No
Reenroll periodic timer : Running, 604815 Sec
```

Related Command

Command	Description

show ap get-crash-dumps-status

```
show ap get-crash-dumps-status ap-name <apname>
```

Description

This command displays the status of the crash dump file transfers to a controller.

Example

The following output is displayed when crash dumps are successfully transferred:

```
Starting command execution, Time: Wed Apr 29 14:59:42 2020

Uploading to controller 10.3.51.100
- nssimem.myap555.0000.2020-04-26_18-52-45.gz, Status: Success(3)
- q6mem.myap555.0000.2020-04-26_18-52-45.gz, Status: Success(3)
- nssddr.myap555.0000.2020-04-26_18-52-45.gz, Status: Success(3)
- imem.myap555.0000.2020-04-26_18-52-45.gz, Status: Success(3)
Finished Command execution

All transfers Successful. Use 'tar crash' to create a crash.tar which can
be extracted via the usual methods from the controller flash directory
```

The following output is displayed when no crash dumps are present in the AP's flash memory:

```
No crash dumps found stored in the AP flash
```

Related Commands

Command	Description
ap get-crash-dumps	This command allows AP coredump files to be transferred to the controller flash memory on demand from the AP flash memory.

Command History

show ap global

```
show ap global ace-table [ace <acenum>| acl <aclnum> | all][acl-table]
```

Description

This command shows the central database of an AP.

Parameter	Description
ace-table	Show ACE table from AP's central database .
ace <acenum>	Dump single ace entry.
acl <aclnum>	Dump ACE entries for a single ACL.
all	Dump all ACE entries.
acl-table	Show ACL table of STM.

Example

The following example shows the ACL table of STM:

```
(host) [mynode] #show ap global acl-table

STM ACL Table
-----
ACL  Type      ACE Index  Ace Count  Name
---  ---
1    session    7680      1          global-sacl
2    role       8132      33         logon

show ap gps

```

advanced
  ap-name
  ip-addr
  ip6-addr
summary
  ap-name
  ip-addr
  ip6-addr

```

Description

This command displays the status of GPS profile of an AP.

Parameter	Description
advanced	Display the raw information of the GPS. NOTE: This parameter is only used for advanced debugging and should only be issued under the direct supervision of Aruba technical support.
ap-name	Display the raw GPS information of an AP specified by its name.
ip-addr	Display the raw GPS information of an AP specified by its IP address.

Parameter	Description
ip6-addr	Display the raw GPS information of an AP specified by its IPv6 address.
summary	Display the summary information of the GPS profile.
ap-name	Display the summary GPS information of an AP specified by its name.
ip-addr	Display the summary GPS information of an AP specified by its IP address.
ip6-addr	Display the summary GPS information of an AP specified by its IPv6 address.

Example

The output of the `show ap gps summary` command displays the summary of the GPS profile in an AP with name AP635.

```
(host) #show ap gps summary ap-name AP635

GPS Information
-----
Type      Position(Latitude, Longitude)  Altitude
-----
$GNRMC    39.4777853, 116.1905834          N/A
$GNGGA    39.4777853, 116.1905834          40.7 M
$GNGLL    39.4777853, 116.1905834          N/A
```

Related Commands

show ap greenap

```
show ap greenap
amon pending-ap {all | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
counters{ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr> | wired-mac
<wired-mac>}
request pending-ap {all | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command displays all the pending APs in the per-md list, sends the AP_INFO AMON message for a particular AP, and track Green AP related counters.

Parameter	Description
amon	AMON message. When AP is in deep-sleep mode, the managed device sends the AP_INFO AMON message for a particular AP. NOTE: The amon command can only be run in the managed device
pending-ap	Displays the pending AP list.
all	Displays the pending AP list for the managed device.
ip-addr	Displays the pending AP list for a particular IP address of the managed device.
ip6-addr	Displays the pending AP list for a particular IPv6 address of the managed device.
counters	Displays all the counters for Green AP. This command is used to track green AP related counters, for example, how many deep-sleep or wake-up requests are received from Netinsight and how many requests are dropped, and so on.
ap-name	Displays the counters for a particular AP name.
ip-addr	Displays the counters for a particular IP address of the managed device.
ip6-addr	Displays the counters for a particular IPv6 address of the managed device.
request	Displays the power-save or wakeup requests for a Green AP. This command is used to display all the pending APs in the per-md list.

Example

The following command helps in debugging and tracking all the requests using counters:

```
show ap greenap counters ap-name <ap-name>
Counters for greenap
-----
Item                                     Value

show ap he-rates

```
show ap he-rates bssid <bssid>
```

Description

This command shows high-efficiency rate information for a BSS.

Parameter	Description
bssid <bssid>	Show data for a specific BSSID on an AP. An AP's BSSID is usually the AP's MAC address.

Examples

The output of this command shows high-efficiency rates for each supported MCS value.

```
(host) [mynode] #show ap he-rates bssid 00:12:6d:03:1c:f1
```

show ap ht-rates

```
show ap ht-rates bssid <bssid>
```

Description

This command shows high-throughput rate information for a BSS.

Parameter	Description
bssid <bssid>	Show data for a specific BSSID on an AP. An AP's BSSID is usually the AP's MAC address.

Examples

The output of this command shows high-throughput rates for each supported MCS value. These values are applicable to high-throughput (802.11n-capable) APs only.

```
(host) [mynode] #show ap ht-rates bssid 00:1a:1e:1e:5a:10
AP "AL12" Radio 0 BSSID 00:1a:1e:1e:5a:10 High-throughput Rates (Mbps)
-----

show ap image version

```
show ap image version [ap-name <ap-name>|ip-addr <ip-addr>]
```

Description

This command shows an AP's image version information. By default, this command displays image version information for all APs associated with the controller. To view image version information for a single AP, specify an AP using the `ap-name` or `ip-addr` parameters.

Parameter	Description
<code>ap-name <ap-name></code>	View image version information for an AP with a specific name.
<code>ip-addr <ip-addr></code>	View image version information for an AP with a specific IP address. Enter the address of the AP in dotted-decimal format.

Example

The output in the example below shows the current running image version as well as the image version stored in the controller's flash memory.

```
(host) [mynode] #show ap image version ip-addr 192.0.2.45
Access Points Image Version
-----
AP                               Running Image Version String
--                               -----
192.0.2.45                       6.4.0.0 Wed Nov 27 10:46:42 PDT 2013

Flash Image Version String      Matches   Num Matches
-----
6.4.0.0 Wed Nov 27 10:46:42 PDT 2013  Yes      3

Num Mismatches   Bad Checksums   Image Load Status
-----
0                -----          Done
```

The output of this command includes the following information:

Parameter	Description
AP	Name or IP address of an AP.

Parameter	Description
Running Image Version String	String identifying the number of the image version currently running on the AP, as well as the date on which that version was created.
Flash Image Version String	String identifying the number of the image version in the AP's flash memory, as well as the date on which that version was created.
Matches	If yes , the running image version matches the image version currently in the AP's flash memory. If no , the two image versions do not match.
Num Matches	Number of times the running image version matched the flash image version after a reboot.
Num Mismatches	Number of times the running image version did not match the flash image version after a reboot. If the images do not match, the AP will upgrade to the flash image.
Bad Checksums	Number of bad checksum calculations due to an invalid or corrupted image file.
Image Load Status	Current status of the AP following an upgrade. <ul style="list-style-type: none"> ■ Done: This status indicates that the controller reset after the upgrade was performed, or the upgrade was performed after the AP first registered with the controller. ■ Completed: The AP was updated after it was registered to the controller, and after the controller's last reset. If AP shows a status of completed, it will also display the time it took it update that AP. ■ In progress: The AP is currently updating its image.

show ap ip health-check

```
show ap ip health-check {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows health of an access point.

Parameter	Description
ap-name <ap-name>	Shows health of an access point specified by AP name.
ip-addr <ip-addr>	Shows health of an access point specified by IP address.
ip6-addr <ip6-addr>	Shows health of an access point specified by IPv6 address.

Example

Access the CLI and use the following command to show health of an access point with IP address 192.0.2.1:

```
(host) [mynode] #show ap ip health-check ip-addr 192.0.2.1

AP Health-Check Status

show ap license-usage

show ap license-usage

Description

This command shows AP license usage information.

Examples

The output of the command below shows that controller has 13 associated campus APs using licenses, with 3 unused campus AP licenses remaining.

```
(host) [mynode] #show ap license-usage

AP Licenses
-----
Type                Number
-----
AP Licenses         512
MM Licenses          500
MC-VA Licenses      0
Controller License  True
Overall AP License Limit 0
AP Usage [Note: THIS CONTROLLER DOES NOT TERMINATE ANY AP]
-----
Type                Count
-----
Active CAPs         0
Active RAPs         0
Remote-node APs     0
Tunneled nodes     0
Total APs           0
Remaining AP Capacity
-----
Type  Number
-----
CAPs  0
RAPs  0
```

The output of this command includes the following information:

Parameter	Description
AP Licenses	Number of AP licenses currently available on the managed device.
RF Protect Licenses	Number of RF Protect licenses currently available on the managed device.

Parameter	Description
PEF Licenses	Number of PEF licenses currently available on the managed device.
Overall AP Licenses	Total number of APs supported by licenses on the managed device.
CAPs	Number of campus APs currently using a license on the managed device.
RAPs	Number of remote APs currently using a license on the managed device.
Remote-Node APs	Number of APs currently using a license on the managed device.
Tunneled Nodes	Number of tunneled nodes currently using a license on the managed device.
CAPs	Number of unused campus APs licenses remaining on the managed device.
RAPs	Number of unused remote APs licenses remaining on the managed device.

Description

Display a list of LLDP-MED Network Policy profiles, or display the current configuration settings of an individual profile.

Parameter	Description
<profile>	Specify a LLDP profile name to view configuration settings for that profile.

Examples

The following example lists all LLDP profiles. The References column lists the number of other profiles with references to that LLDP-MED Network policy profile, and the ProfileStatus column indicates whether the profile is predefined.

The output of the command below shows that the controller has two LLDP profiles.

```
(host) #show ap lldp med-network-policy-profile
AP LLDP Profile List
-----
Name      References  Profile Status
-----
default   0
video     2
Total:2
The following command displays configuration details for the LLDP profile
named default.

(host) [mynode] #show ap lldp med-network-policy-profile video
AP LLDP Profile "new"
-----
Parameter                               Value
-----
PDU transmission                         Enabled
Reception of LLDP PDUs                  Enabled
Transmit interval (seconds)              30
Transmit hold multiplier                  4
Optional TLVs                            port-description system-description system-
name capabilities management-address
802.1 TLVs                               port-vlan vlan-name
802.3 TLVs                               mac link-aggregation mfs power
LLDP-MED TLVs
LLDP-MED network policy profile         N/A
```

The output of this command includes the following information:

Parameter	Description
PDU transmission	Shows if LLDP PDU transmission is enabled on the AP.
Reception of LLDP PDUs	Shows if LLDP PDU reception is enabled on the AP.
Transmit interval (seconds)	The interval between LLDP TLV transmission seconds. The supported range is 1-3600 seconds and the default value is 30 seconds.
Transmit hold multiplier	This value is multiplied by the transmit interval to determine the number of seconds to cache learned LLDP information before that information is cleared. If the transmit-hold value is at the default value of 4, and the transmit interval is at its default value of 30 seconds, then learned LLDP information will be cached for 4 x 30 seconds, or 120 seconds.
Optional TLVs	The AP sends the listed optional TLVs in LLDP PDUs.
802.1 TLVs	The AP sends the listed 802.1 TLVs in LLDP PDUs. By default, the AP will send all 802.1 TLVs.
802.3 TLVs	The AP sends the listed 802.3 TLVs in LLDP PDUs. By default, the AP will send all 802.3 TLVs.
LLDP-MED TLVs	Lists the LLDP-MED TLVs the AP will send in LLDP PDUs. By default, the AP will not send any LLDP-MED TLVs
LLDP-MED network policy profile	Specifies the LLDP MED Network Policy profile to be associated with this LLDP profile.

show ap lldp counters

```
show ap lldp counters
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr (ipv6-addr)
```

Description

This command shows LLDP counters for a specific AP, or all APs sending or receiving LLDP Protocol Data Units (PDUs).

Parameter	Description
ap-name <ap-name>	Show counter statistics for an AP with a specific name.
ip-addr <ip-addr>	View counter statistics for an AP with a specific IP address. Enter the IP address of the AP in dotted-decimal format.
ip6-addr <ip-addr>	View counter statistics for an AP with a specific IPv6 address.

Examples

The output of the command below shows LLDP counter information for two interfaces.

```
(host) [mynode] #show ap lldp counters
AP LLDP Counters (Updated every 60 seconds)
-----
AP          Interface  Received  Unknown TLVs  Malformed  Overflow
Transmitted
--          -
-----
00:1a:1e:ce:fb:bf bond0      0          0              0          0
68159
00:24:6c:c0:00:86 bond0      0          0              0          0
68153
```

The output of this command includes the following information:

Parameter	Description
AP	Name of the AP sending or receiving LLDP PDUs.
Interface	Name of the AP interface sending or receiving LLDP PDUs.
Received	Number of packets received on the specified interface.

Parameter	Description
Unknown TLVs	Number of LLDP Protocol Data Units (PDUs) with an unknown type-length-value (TLV).
Number of Malformed packets	Number of malformed packets received on that interface.
Overflow	Number of times that an LLDP neighbor could not be added to the neighbor table (there is a limit of 8 per port).
Transmitted	Number of packets transmitted from that interface.

show ap lldp med-network-policy-profile

show ap lldp med-network-policy-profile [<profile>]

Description

This command shows a list of LLDP-MED Network Policy profiles, or display the current configuration settings of an individual profile. The LLDP-MED Network policy profile allows you to configure an extension to LLDP that supports interoperability between VoIP devices and other networking clients. LLDP-MED network policy discovery lets end-points and network devices advertise their VLAN IDs (e.g. voice VLAN), priority levels, and DSCP values. allows you to define a set of provisioning parameters to an AP group.

Issue this command without the **<profile-name>** option to display the entire LLDP-MED Network policy profile list, including profile status and the number of references to each profile. Include a profile name to display the configuration settings for that profile.

Parameter	Description
<profile>	Specify a LLDP-MED Network Policy profile name to view configuration settings for that profile.

Examples

The following example lists all LLDP-MED Network policy profile profiles. The **References** column lists the number of other profiles with references to that LLDP-MED Network policy profile, and the **Profile Status** column indicates whether the profile is predefined.

The output of the command below shows that the controller has three LLDP-MED network profiles.

```
(host) [mynode] #show ap lldp med-network-policy-profile

AP LLDP-MED Network Policy Profile List
-----
Name      References  Profile Status
----      -
default   0
video     2
voice     1
Total:2
The following command displays configuration details for the LLDP-MED
Network Policy profile named video.

(host) #show ap lldp med-network-policy-profile video
AP LLDP-MED Network Policy Profile "default"
-----
Parameter                                     Value
```

```

-----
LLDP-MED application type                streaming-video
LLDP-MED application VLAN                16
LLDP-MED application VLAN tagging        Tagged
LLDP-MED application Layer-2 priority    0
LLDP-MED application Differentiated Services Code Point 0

```

The output of this command includes the following information:

Parameter	Description
LLDP-MED application type	<p>Type of application that this profile manages. This profile supports the following options:</p> <ul style="list-style-type: none"> ■ guest-voice: The AP services a separate voice network for guest users and visitors. ■ guest-voice-signaling: The AP is part of a network that requires a different policy for guest voice signaling than for guest voice media. Do not use this application type if both the same network policies apply to both guest voice and guest voice signaling traffic. ■ softphone-voice : The AP supports voice services using softphone software applications on devices such as PCs or laptops. ■ streaming-video: T The AP supports broadcast or multicast video or other streaming video services that require specific network policy treatment. This application type is not recommended for video applications that rely on TCP with buffering. ■ video-conferencing: T The AP supports video conferencing equipment that provides real-time,

Parameter	Description
	<p>interactive video/audio services.</p> <ul style="list-style-type: none"> ■ video-signaling: T The AP is part of a network that requires a different policy for video signaling than for the video media. Do not use this application type if both the same network policies apply to both video and video signaling traffic. ■ voice: The AP services IP telephones and other appliances that support interactive voice services. This is the default application type. ■ voice-signaling: The AP is part of a network that requires a different policy for voice signaling than for the voice media. Do not use this application type if both the same network policies apply to both voice and voice signaling traffic.
LLDP-MED application VLAN	Indicates the VLAN ID (0-4094) or VLAN name of the VLAN used by the application.
LLDP-MED application VLAN tagging	<p>Indicates if the policy applies to a to a VLAN that is tagged with a VLAN ID or untagged. The default value is untagged.</p> <p>NOTE: When an LLDP-MED network policy is defined for use with an untagged VLAN, then the L2 priority field is ignored and only the DSCP value is used.</p>

Parameter	Description
LLDP-MED application Layer-2 priority	Displays a configured 802.1p priority level for the specified application type, where 0 is the lowest priority level and 7 is the highest priority.
LLDP-MED application Differentiated Services Code Point	Displays a configured Differentiated Services Code Point (DSCP) priority value for the specified application type, where 0 is the lowest priority level and 63 is the highest priority.

Related Commands

Command	Description

show ap lldp neighbors

```
show ap lldp neighbors
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr (ipv6-addr)
```

Description

This command shows LLDP neighbors for a specific AP, or all APs sending or receiving LLDP Protocol Data Units (PDUs). The LLDP protocol allows switches, routers, and WLAN access points to advertise information about themselves such as identity, capabilities, and neighbors to other nodes on the network. Use this command to display information about the AP's LLDP peers.

By default, this command displays LLDP neighbors for the entire list of LLDP interfaces. Include a the name of IP address of an AP to display neighbor information only for that one device.

Parameter	Description
ap-name <ap-name>	Show LLDP neighbor statistics for an AP with a specific name.
ip-addr <ip-addr>	View LLDP neighbor statistics for an AP with a specific IP address. Enter the IP address of the AP in dotted-decimal format.
ip6-addr <ip-addr>	View LLDP neighbor statistics for an AP with a specific IPv6 address.

Examples

The output of the command below shows the LLDP neighbor list for an AP named **ap12**.

```
(host) [mynode] #show ap lldp neighbors ap-name ap12
AP LLDP Neighbors (Updated every 60 seconds)
-----
AP Interface Neighbor Chassis Name/ID Port Name/ID Mgmt. Address
Capabilities
--
-----
uc bond0 0 d8:c7:c8:c4:4f:4e bond0 10.3.44.193
Capability codes: (R)Router, (B)Bridge, (A)Access Point, (P)Phone, (O)Other
```

The output of this command includes the following information:

Parameter	Description
AP	Name of the LLDP neighbor
Interface	Interface on the AP sending or receiving LLDP PDUs.
Neighbor	LLDP neighbor number
Chassis Name/ID	The name of the LLDP neighbor AP
Port Name/ID	Port name or ID if the interface sending LLDP PDUs.
Mgmt. Address	Management address of the LLDP neighbor
Capabilities	This data column can list any of the following data codes to indicate LLDP neighbor capabilities. <ul style="list-style-type: none"> ■ R: Router ■ B: Bridge ■ A: Access Point ■ P: Phone ■ O: Other

show ap load-balancing

```
show ap load balancing
```

Description

This command shows the load-balancing information for each AP with load balancing enabled.

Examples

The output of the command in the example below shows details for a single AP enabled with the load-balancing feature.

```
(host) [mynode] #show ap load-balancing
Load Balance Enabled Access Point Table
-----
bss          ess          name    s/p  ip          phy    chan  cur-cl  util (kbps)
---          ---          ----    --  --          ---    ----  -
00:0b:86:cc:8e:4e Wireless_1  mp22    2/24  10.3.148.12 a-HT   413   3       14
```

The output of this command includes the following information:

Column	Description
BSS	The BSS Identifier for the AP. This is usually the APs MAC address.
ESS	The ESS Identifier is the user-defined name of an 802.11 wireless network.
s/p	The controller slot and port used by the AP, in the format <slot>/<module>/<port>.
ip	IP address of the AP.
phy (For versions prior to ArubaOS 8.9.0.0)	Displays one of the following 802.11 radio types: <ul style="list-style-type: none">■ a■ a-HT (high-throughput)■ g■ g-HT (high-throughput)
Phy-type (ArubaOS 8.9.0.0 or later versions)	Displays one of the following 802.11 radio types: <ul style="list-style-type: none">■ 2.4GHz■ 5GHz■ 6GHz

Column	Description
chan	Channel number for the AP 802.11a/802.11n physical layer. The available channels depend on the AP's regulatory domain (country).
cur-cl	Current number of clients on the AP.
util (kbps)	Current bandwidth utilization, in kbps.

Related Commands

Command	Description

show ap mesh active

```
show ap mesh active [<mesh-cluster>|{page <page>}|{start <start>}]
```

Description

This command shows active mesh cluster APs currently registered on this Mobility Conductor.

Parameter	Description
<mesh-cluster>	Name of a mesh cluster profile.
page <page>	Limit the output of this command to a specific number of entries by entering the number of entries you want to display.
start <start>	Start displaying the index of mesh APs at a chosen index number by entering the index number of the AP at which command output should start.

Example

The following example displays a list of all active mesh points and mesh portals (For versions prior to ArubaOS 8.9.0.0).

```
(host)[mynode] #show ap mesh active
Mesh Cluster Name: mesh-515
-----
Name      Group      IP Address      AP Type  Uptime          Mesh Role  MTU

Off/Bridge ap635-3 0
          6GHz/169S/20.0/21.5

Total APs :2
```

The output of this command includes the following information:

Column	Description
Name	Name of an AP.
Group	AP group which includes the specified AP.
IP Address	IP address of the AP.
AP type	The AP model type.
Uptime	Number of hours, minutes and seconds since the last Mobility Conductor reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .
Mesh Role	An AP operating as a mesh node can have one of two roles: mesh portal or mesh point.
MTU	MTU size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.

Column	Description
Enet Ports	Shows one of the following current modes of each wired interface: <ul style="list-style-type: none"> ■ Bridge: 802.11 frames are bridged into the local Ethernet LAN. ■ Tunnel: 802.11 frames are tunneled to the Mobility Conductor using GRE. ■ Split-tunnel: 802.11 frames are either bridged into the local Ethernet LAN or tunneled to the Mobility Conductor, depending upon their destination. ■ Off: Interface is not available for serving clients. If an AP has only one wired interface, the output of this command will display a dash (-) for the unavailable port.
Parent	If the AP is operating as a mesh point, this parameter displays the name of its parent mesh portal. Mesh portals will display a dash (-).
#Children	If the AP is operating as a mesh portal, this parameter shows the number of mesh point children associated with that mesh portal.
Band/Ch/EIRP/MaxEIRP	The RF band in which the AP should operate (a or g)/radio channel used by the AP/current EIRP /maximum EIRP. <p>NOTE: For Wi-Fi 6E APs in ArubaOS 8.9.0.0 or later versions, the RF band displays one of the following values:</p> <ul style="list-style-type: none"> ■ 2.4 GHz ■ 5 GHz ■ 6 GHz

All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap mesh debug counters

```
show ap mesh debug counters {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

Description

This command shows counters statistics for a mesh node.

Parameter	Description
ap-name <ap-name>	Show counter statistics for an AP with a specific name.
bssid <bssid>	Show counter statistics for a specific BSSID on an AP. An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	View counter statistics for an AP with a specific IP address. Enter the IP address of the AP in dotted-decimal format.

Example

The example below shows the Mesh Packet Counters table for an AP named meshpoint1. The **Probe Resp**, **Assoc Req**, and **Assoc Resp** data columns show both the total number of counters and, in parenthesis, the number of requests or responses with high-throughput information elements (HE IEs).

```
(host) [mynode] #show ap mesh debug counters ap-name meshpoint1
Mesh Packet Counters
-----
Interface  Echo Sent  Echo Recv  Probe Req  Probe Resp  Assoc Req  Assoc

```

The output of this command includes the following information:

Column	Description
Interface	Indicates whether the mesh interface connects to a Parent AP or a Child AP. Each row of data in the <i>Mesh Packet Counters</i> table shows counter values for an individual interface.
Echo Sent	Number of echo packets sent.
Echo Recv	Number of echo packets received.
Probe Req	Number of probe request packets sent from the interface specified in the Mesh-IF parameter.
Probe Resp	Number of probe response packets sent to the interface specified in the Interface parameter.
Assoc Req	Number of association request packets from the interface specified in the <i>Interface</i> parameter.
Assoc Resp	Number of association response packets from the interface specified in the Interface parameter. This number includes valid responses and fail responses.
Assoc Fail	Number of fail responses received from the interface specified in the Interface parameter.
Link up/down	Number of times the link up or link down state has changed.
Resel.	Number of times a mesh point attempted to reselect a different mesh portal.
Switch	Number of times a mesh point successfully switched to a different mesh portal.
Other Mgmt	Management frames of any type other than association and probe frames, either received on child interface, or sent on parent interface.

show ap mesh debug current-cluster

```
show ap mesh debug current-cluster
  ap-name <ap-name>
  bssid <bssid>
  ip-addr <ip-addr>
```

Description

This command shows the AP mesh debug information for the mesh cluster currently used by a mesh point or mesh portal.

Parameter	Description
ap-name <ap-name>	Shows AP mesh debug information for the specified AP name.
bssid <bssid>	Shows AP mesh debug information for the specified BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Shows AP mesh debug information for the specified IP address.

Examples

The example shows the AP mesh debug information of an AP named **mp2**.

```
(host) [mynode] #show ap mesh debug current-cluster ap-name mp2

AP "mp2" Current Cluster Profile: default
-----
Item                Value
----                -
Cluster Name       smettu-mesh
RF Band            a
Encryption         opensystem
WPA Hexkey         N/A
WPA Passphrase     *****
```

The output of this command includes the following information:

Column	Description
Cluster Name	Name of the mesh cluster using this profile
RF band	The RF band in which the mesh point or mesh portal operates: <ul style="list-style-type: none">■ g = 2.4 GHz

Column	Description
	<ul style="list-style-type: none"> ■ a = 5 GHz
Encryption	Data encryption setting for the mesh cluster profile. <ul style="list-style-type: none"> ■ opensystem—No authentication and encryption. ■ wpa2-psk-aes—WPA2 with AES encryption using a preshared key.
WPA Hexkey	The WPA pre-shared key (only for mesh cluster profiles using WPA2 with AES encryption).
WPA Passphrase	The WPA password that generates the preshared key (only for mesh cluster profiles using WPA2 with AES encryption).

show ap mesh debug forwarding-table

```
show ap mesh forwarding-table [ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>]
```

Description

This command displays the forwarding table for a remote mesh point or remote mesh portal. This is an internal technical support command. Aruba technical support may request that you issue this command to help analyze and troubleshoot problems with your mesh network.

Parameter	Description
ap-name <ap-name>	Show data for a remote mesh node with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for a remote mesh node with a specific IP address by entering its IP address in dotted-decimal format.

show ap mesh debug meshd-log

```
show ap mesh debug meshd-log {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>} [<page>]
```

Description

Show the debug log messages for the **meshd** process. This is an internal technical support command. Aruba technical support may request that you issue this command to help analyze and troubleshoot problems with the **meshd** process or your mesh network.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address by entering an IP address in dotted-decimal format.
<page>	Display page number 0, 1, or 2, where page 0 has the newest information and page 2 has the oldest. If this parameter is omitted, this command will display all meshd log information, oldest first.

show ap mesh debug provisioned-clusters

```
show ap mesh debug provisioned-clusters
  ap-name <ap-name>
  bssid <bssid>
  ip-addr <ip-addr>
```

Description

This command shows the cluster profiles provisioned on a mesh portal or mesh point.

Parameter	Description
ap-name <ap-name>	Shows AP mesh debug log messages for the specified AP name.
bssid <bssid>	Shows AP mesh debug log messages for the specified BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Shows AP mesh debug log messages for the specified IP address.

Example

The example shows the statistics for the APs mesh cluster profile and recovery cluster profile on an AP mesh point named portal2.

```
(host) [mynode] #show ap mesh debug provisioned-clusters ap-name portal2

AP Portal Cluster Profile: mesh-cluster-profile
-----
Parameter      Value
-----
Cluster Name   sw-ad-GB32
RF Band        a
Encryption     opensystem
WPA Hexkey     N/A
WPA Passphrase *****

AP "Portal" Cluster Profile: Recovery Cluster Profile
-----
Item           Value
-----
Cluster Name   Recovery-ZF-xAP15z-g15VN
RF Band        a
Encryption     pa2-psk-aes
WPA Hexkey     *****
WPA Passphrase N/A
```

The output of this command displays the following information for the AP's mesh cluster profile and recovery cluster profiles:

Column	Description
Cluster Name	Name of the mesh cluster using this profile
RF band	The RF band in which the AP should operate: <ul style="list-style-type: none"> ■ g = 2.4 GHz ■ a = 5 GHz
Encryption	Data encryption setting for the mesh cluster profile. <ul style="list-style-type: none"> ■ opensystem—No authentication and encryption. ■ wpa2-psk-aes—WPA2 with AES encryption using a preshared key.
WPA Hexkey	The WPA pre-shared key (only for mesh cluster profiles using WPA2 with AES encryption).
WPA Passphrase	The WPA password that generates the preshared key (only for mesh cluster profiles using WPA2 with AES encryption).

show ap mesh debug status

```
show ap mesh debug status
  ap-name <ap-name>
  bssid <bssid>
  ip-addr <ip-addr>
```

Description

This command shows mesh internal status of a mesh node.

Parameter	Description
ap-name <ap-name>	Shows AP mesh debug log messages for the specified AP name.
bssid <bssid>	Shows AP mesh debug log messages for the specified BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Shows AP mesh debug log messages for the specified IP address.

Example

The following example displays the mesh internal status of a mesh node:

```
(host) [mynode] #show ap mesh debug status ap-name ap225

show ap mesh monitor

```
show ap mesh monitor
  info [ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>]
  stats [ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>]
```

Description

This command shows the mesh monitor information of APs.

Parameter	Description
info	Shows topology info of a mesh node.
stats	Shows statistics of a mesh link.
ap-name <ap-name>	Shows AP mesh log messages for the specified AP name.
bssid <bssid>	Shows AP mesh log messages for the specified BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Shows AP mesh log messages for the specified IP address.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Configuration mode on Mobility Conductor.

show ap mesh neighbors

```
show ap mesh neighbors {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
[names]
```

Description

This command shows all mesh neighbors for an AP.

Parameter	Description
ap-name <ap-name>	Show mesh neighbors for an AP with a specific name.
bssid <bssid>	Show mesh neighbors for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show mesh neighbors for an AP with a specific IP address by entering its IP address in dotted-decimal format.
names	If you include this optional parameter, the Portal column in the output of this command will translate the BSSIDs of mesh parent and child APs to AP names (where available).

Example

In the example below, the output has been split into two tables to better fit on the page. In the actual CLI, the output appears in a single, wide table.

The **Flags** column in the output of this command indicates the high-throughput (HT) properties of the mesh node. In the example below, the string "HT-40MHzsgi-2ss" indicates that the node uses a 40MHz channel with a short guard interval (sgi) and sends 2 spatial streams (ss) (For versions prior to ArubaOS 8.9.0.0).

```
(host) [mynode] #show ap mesh neighbors ap-name portal

Neighbor list

```

The output of this command includes the following information:

Column	Description
Radio	Identifies which radio the mesh neighbor belongs to.
MAC	MAC address of the mesh node.
AP Name (ArubaOS 8.9.0.0 or later versions)	Name of the mesh AP.
Portal	By default, this column displays the BSSID of the mesh point. If you include the optional <code>names</code> parameter, this column will display AP names, if available. The AP names will include [p] (parent), or [c] (child) suffixes to indicate the role of the mesh BSSID.
Channel	Number of a radio channel used by the AP.
Band (ArubaOS 8.9.0.0 or later versions)	The radio band for the mesh AP.
Age	Number of seconds elapsed since the AP heard from the neighbor.
Hops	Indicates the number of hops it takes traffic from the mesh node to get to the mesh portal. The mesh portal advertises a hop count of 0, while all other mesh nodes advertise a cumulative count based on the parent mesh node
Cost	A relative measure of the quality of the path from the AP to the controller. A lower number indicates a better quality path, where a higher number indicates a less favorable path (e.g, a path which may be longer or more congested than a path with a lower value.) For a mesh point, the path cost is the sum of the (parent path cost) + (the parent node cost) + (the link cost).
Relation	Shows the relationship between the specified AP and the AP on the neighbor list and the amount of time that relationship has existed. <ul style="list-style-type: none"> ▪ P = Parent ▪ C = Child ▪ N = Neighbor ▪ B = Blacklisted-neighbor/Denylisted-neighbor
Flags	This parameter shows additional information about the mesh neighbor. The key describing each flag appears at the bottom of the neighbor list.

Column	Description
RSSI	The RSSI value displayed in the output of this command represents signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.
Rate Tx/Rx	The rate, in Mbps, that a neighbor transmits data to or receives data from the mesh-node specified by the command.
A-Req	Number of association requests from clients
A-Resp	Number of association responses from the mesh node
A-Fail	Number of association failures
Cluster	Name of the Mesh cluster that includes the specified AP or BSSID.

Related Commands

Command	Description
ap mesh-radio-profile	This command configures a mesh radio profile used by mesh nodes.

Command History

Release	Modification
ArubaOS 8.9.0.0	The following changes were made: <ul style="list-style-type: none"> All instances of <code>Blacklisted-neighbour</code> have been replaced with <code>Denylisted-neighbour</code>. The output of the command was modified to display the <code>AP Name</code> and <code>Band</code> parameters.
ArubaOS 8.8.0.0	The output of the command was modified to display the <code>m</code> flag.
ArubaOS 8.7.0.0	The output was modified to include the <code>Radio</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap mesh tech-support

```
show ap mesh tech-support ap-name <ap-name> <filename>
```

Description

This command shows all information for an AP, and saves that information in a file on the controller. This command displays the output of the multiple mesh and debug CLI commands, then saves that data into a report file on the controller's flash drive, where it can be analyzed for debugging purposes. The information in this report includes the output of the following commands:

- [show ap mesh neighbors](#)
- [show ap mesh debug current-cluster](#)
- [show ap mesh debug provisioned-clusters](#)
- [show ap mesh debug counters](#)
- [show ap mesh debug forwarding-table](#)
- [show ap mesh debug meshd-log](#)
- [show ap mesh debug hostapd-log](#)

Parameter	Description
<ap-name>	Name of an AP for which you want to create a report.
<filename>	Filename for the report created by this command. The file can only be saved in the flash directory. If desired, you can use FTP or TFTP to copy the file to another destination.

Related Commands

show ap mesh topology

```
show ap mesh topology [long] [page <page>] [start <start>]
```

Description

This command shows the mesh topology tree.

Parameter	Description
long	Include the names of a mesh portal's children in the output of this command.
page <page>	Limit the output of this command to a specific number of entries by entering the number of entries you want to display.
start <start>	Start displaying the mesh topology tree at a chosen index number by entering the index number of the AP at which command output should start.

Examples

An **(N)** in the **Mesh Role** column indicates the node is 11N capable. An **(N)** beside the parent name in the **Parent** column indicates that the mesh node's the parent is also 11N capable.

```
(Aruba9012_DA_90_B0) [mynode] # show ap mesh topology

(HE): 11AX Enabled. For Portals 'Uplink Age' equals uptime.
ACTV: Active on controller, REPL: Replicated on controller.
```

The output of this command includes the following information:

Column	Description
Name	Name of the mesh node.
State	State of the mesh node.
IP Address	IP address of the mesh node.
Switch IP	IP address of the controller.
Mesh Role	An AP operating as a mesh node can have one of two roles: mesh portal or mesh point.
Radio	Mesh radio number of the AP.
BSSID	BSSID for the AP. This is usually the AP's MAC address.
Parent	If the AP is operating as a mesh point, this parameter displays the name of its parent mesh portal.
Path Cost	A relative measure of the quality of the path from the AP to the controller. A lower number indicates a better quality path, where a higher number indicates a less favorable path (e.g, a path which may be longer or more congested than a path with a lower value.) For a mesh point, the path cost is the sum of the (parent path cost) + (the parent node cost) + (the link cost).
Node Cost	A relative measure of the quality of the node, where a lower number of is more favorable than a higher number. This cost is related to the number of children on the specified node.
Link Cost	A relative measure of the quality of the link. For example, a more congested link will have a higher link cost than a similar, less-congested link.
Hop Count	Number of hops to the mesh portal.
RSSI	The RSSI value displayed in the output of this command represents signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.
Rate Tx/Rx	The rate, in Mbps, that a mesh point transmits and receives at on its uplink. Note that the rate information is only as current as indicated in the Last Update column.
Last Update	Time elapsed since the mesh node last updated its statistics.
Uplink Age	Time elapsed since the mesh node became active in the mesh topology.
#Children	Number of children associated with a parent mesh point.

show ap mesh-cluster-profile

```
show ap mesh-cluster-profile [<profile>]
```

Description

This command shows configuration settings for a mesh cluster profile. The command **show ap mesh-cluster-profile** displays a list of all mesh cluster profiles configured on the Mobility Conductor, including the number of references to each profile and each profile's status. Include the optional <profile> parameter to show detailed settings for an individual mesh cluster profile.

Parameter	Description
<profile>	Name of a mesh cluster profile

Examples

The example below shows the configuration settings for the mesh cluster profile "meshcluster2".

```
(host)[mynode] #show ap mesh-cluster-profile meshcluster2

Mesh Cluster profile "meshcluster2"
-----
Parameter      Value
-----
Cluster Name   company-mesh
RF Band        a
Encryption     opensystem
WPA Hexkey     N/A
WPA Passphrase N/A
```

The output of this command includes the following information:

Parameter	Description
Cluster Name	Name of the mesh cluster using this profile
RF band	The RF band in which the AP should operate: <ul style="list-style-type: none">■ g = 2.4 GHz■ a = 5 GHz
Encryption	Data encryption setting for the mesh cluster profile. <ul style="list-style-type: none">■ opensystem—No authentication and encryption.■ wpa2-psk-aes—WPA2 with AES encryption using a preshared key.

Parameter	Description
WPA Hexkey	The WPA PSK (only for mesh cluster profiles using WPA2 with AES encryption).
WPA Passphrase	The WPA password that generates the preshared key (only for mesh cluster profiles using WPA2 with AES encryption).

show ap mesh-ht-ssid-profile

show ap mesh-ht-ssid-profile [<profile>]

Description

This command shows configuration settings for a mesh high-throughput Service Set Identifier (SSID) profile. High-throughput APs support additional settings not available in legacy APs. A mesh high-throughput SSID profile can enable or disable high-throughput (802.11n) features and 40 Mhz channel usage, and define values for aggregated MAC protocol data units (MDPUs) and Modulation and Coding Scheme (MCS) ranges.

This command shows a list of all mesh high-throughput SSID profiles configured on the Mobility Conductor, including the number of references to each profile and each profile's status. Include the optional <profile> parameter to show detailed settings for an individual mesh high-throughput SSID profile.

Parameter	Description
<profile>	Name of a mesh high-throughput SSID profile.

Examples

The example below shows the configuration settings for the mesh high-throughput radio profile "default".

```
(host) [mynode] #show ap mesh-ht-ssid-profile default

Mesh High-throughput SSID profile "default"
-----
Parameter                                     Value
-----
40 MHz channel usage                           Enabled
BA AMSDU Enable                                Enabled
Temporal Diversity Enable                       Disabled
High throughput enable (SSID)                  Enabled
Legacy stations                                 Allowed
Low-density Parity Check                       Enabled
Maximum number of spatial streams usable for STBC reception 1
Maximum number of spatial streams usable for STBC transmission 1
MPDU Aggregation                               Enabled
Max received A-MPDU size                        65535 bytes
Max transmitted A-MPDU size                     65535 bytes
Min MPDU start spacing                          8 usec
Short guard interval in 20 MHz mode             Enabled
Short guard interval in 40 MHz mode             Enabled
Supported MCS set                               0-23
Explicit Transmit Beamforming                   Disabled
```

Transmit Beamforming Compressed Steering	Enabled
Transmit Beamforming non Compressed Steering	Enabled
Transmit Beamforming delayed feedback support	Enabled
Transmit Beamforming immediate feedback support	Enabled
Transmit Beamforming Sounding Interval	1800 sec

The output of this command includes the following information:

Column	Description
40 MHz channel usage	This parameter shows if the profile enables or disables the use of 40 MHz channels.
BA AMSDU Enable	Shows if the AP has enabled or disabled the ability to receive AMSDU in BA negotiation.
Temporal Diversity Enable	Shows if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries.
High throughput enable (SSID)	Shows if 802.11n high-throughput features are enabled or disabled for this profile. By default, high-throughput features are enabled.
Legacy stations	Allow or disallow associations from legacy (non-HT) stations. By default, this parameter is enabled (legacy stations are allowed).
Low-density Parity Check	If enabled, the AP will advertise LDPC support. LDPC improves data transmission over radio channels with high levels of background noise.
Maximum number of spatial streams usable for STBC reception	Shows the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the 130 Series, 170 Series, and AP-105 only. The configured value will be adjusted based on AP capabilities.) NOTE: If transmit beamforming is

Column	Description
	enabled, STBC will be disabled for beamformed frames.
Maximum number of spatial streams usable for STBC transmission	Shows the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on 170 Series, 130 Series, and AP-105 only. The configured value will be adjusted based on AP capabilities.) NOTE: If transmit beamforming is enabled, STBC will be disabled for beamformed frames.
MPDU Aggregation	Shows if the profile enables or disables MPDU aggregation.
Max received A-MPDU size	Configured maximum size of a received aggregate MPDU, in bytes.
Max transmitted A-MPDU size	Configured maximum size of a transmitted aggregate MPDU, in bytes.
Min MPDU start spacing	Configured minimum time between the start of adjacent MPDUs within an aggregate MPDU, in microseconds.
Supported MCS set	Displays a list of MCS values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20MHz vs. 40MHz) and the number of spatial streams used by the mesh node.
Short guard interval in 20 MHz mode	Shows if the profile enables or disables use of short (400ns) guard interval in 20 MHz mode.
Short guard interval in 40 MHz mode	Shows if the profile enables or disables use of short (400ns) guard interval in 40 MHz mode.
Explicit Transmit Beamforming	Shows if Explicit Transmit Beamforming is enabled or disabled for 130 Series APs.

Column	Description
	NOTE: If this parameter is disabled, the other transmit beamforming configuration settings have no effect.
Transmit Beamforming Compressed Steering	When enabled, the AP can use explicit compressed feedback from clients to obtain a steering matrix. (For 130 Series APs only.)
Transmit Beamforming non Compressed Steering	When enabled, the AP can use explicit noncompressed feedback from clients to obtain a steering matrix. (For 130 Series only)
Transmit Beamforming delayed feedback support	Shows if the AP has enabled or disabled delayed feedback/report support in Transmit Beamforming. (For 130 Series only)
Transmit Beamforming immediate feedback support	Shows if the AP has enabled or disabled immediate feedback/report support in Transmit Beamforming. (For 130 Series only)
Transmit Beamforming Sounding Interval	Time interval in seconds between updates of Transmit Beamforming channel estimation. (For 130 Series only)

show ap mesh-radio-profile

show ap mesh-radio-profile [<profile>]

Description

This command shows configuration settings for a mesh radio profile. The radio profile determines the radio frequency/channel used only by mesh nodes to establish mesh links. Mesh nodes operating in different cluster profiles can share the same radio profile. Conversely, mesh portals using the same cluster profile can be assigned different mesh radio profiles to achieve frequency separation.

This command shows a list of all mesh radio profiles configured on the controller, including the number of references to each profile and each profile's status. Include the optional <profile> parameter to show detailed settings for an individual mesh radio profile.

Parameter	Description
<profile>	Name of a mesh radio profile.

Example

The example below shows the configuration settings for the mesh cluster profile "default".

```
(host) [mynode] #show ap mesh-radio-profile default
Mesh Radio profile "default"
-----
Parameter                                     Value
-----
802.11a Transmit Rates                        6 9 12 18 24
36 48 54
802.11g Transmit Rates                        1 2 5 6 9 11
12 18 24 36 48 54
Allowed VLANs on mesh link                    1-4094
BC/MC Rate Optimization                       Enabled
Heartbeat threshold                           10
Link Threshold                                12
Maximum Children                              64
Maximum Hop Count                             8
Mesh Private Vlan                             0
Mesh High-throughput SSID Profile             default
Mesh Survivability                           Disabled
Metric algorithm                              distributed-
tree-rssi
Rate Optimization for delivering EAPOL frames and mesh echoes Disabled
Reselection mode                              startup-
subthreshold
Retry Limit                                   8
RTS Threshold                                 2333 bytes
```

Mesh Mobility	Disabled
Mobility RSSI Threshold	15
Mobility Beacon Miss Number	16

The output of this command includes the following information:

Parameter	Description
802.11a Transmit Rates	Indicates the transmit rates for the 802.11a radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.
802.11g Transmit Rates	Indicates the transmit rates for the 802.11g radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.
Allowed VLANs on mesh link	Specify a list of VLAN IDs that can be used by a mesh link on APs associated with this mesh radio profile
BC/MC Rate Optimization	If enabled, the mesh node will use the slowest associated mesh-point rate for broadcast/multicast data (rather than minimum).
Heartbeat Threshold	Indicates the maximum number of heartbeat messages that can be lost between neighboring mesh nodes before the mesh node is considered inactive and is dropped as a mesh neighbor.
Link Threshold	Indicates the threshold for the lowest acceptable RSSI value. Links that drop below this threshold will have an increased link cost. Default: 12.

Parameter	Description
Maximum Children	The maximum number of children a mesh portal can accept.
Maximum Hop Count	The maximum number of hops allowed between a mesh point and a mesh portal.
Mesh Private Vlan	This parameter is experimental and reserved for future use.
Mesh High-throughput SSID Profile	The High-throughput SSID Profile associated with this mesh radio profile.
Mesh Survivability	This parameter shows if mesh points and portals can become active even if the controller cannot be reached by bridging LAN traffic. This is a beta feature that is disabled by default; it should not be enabled unless you are instructed to do so by Aruba technical support.
Metric algorithm	Algorithm used by a mesh node to select its parent.
Rate Optimization for delivering EAPOL frames and mesh echoes	If this option is enabled, mesh APs will use a more conservative rate for more reliable delivery of EAPOL frames.
Reselection Mode	<p>Specifies one of the following methods used to find a better mesh link.</p> <ul style="list-style-type: none"> startup-sub-threshold: When bringing up the mesh network, mesh nodes have 3 minutes to find a better uplink. After that time, each mesh node evaluates alternative links only if the existing uplink falls below the configured threshold level (the link becomes a sub-threshold link). The reselection process is canceled if the average RSSI rises on the existing uplink rises above the configured link threshold.

Parameter	Description
	<ul style="list-style-type: none"> ■ reselect-any-time: Connected mesh nodes evaluate alternative mesh links every 30 seconds. If a mesh node finds a better uplink, the mesh node connects to the new parent to create an improved path to the mesh portal. ■ reselect-never: Connected mesh nodes do not evaluate other mesh links to create an improved path to the mesh portal. ■ subthreshold-only: Connected mesh nodes evaluate alternative links only if the existing uplink becomes a sub-threshold link.
Retry Limit	Maximum number of times a mesh node can re-send a packet.
RTS Threshold	The packet size sent by mesh nodes. Mesh nodes transmitting frames larger than this threshold must issue RTS and wait for other mesh nodes to respond with CTS to begin transmission. This helps prevent mid-air collisions.
Mesh Mobility	Displays if fast roaming on a mobility mesh point is enabled or disabled based on low RSSI or missed beacon frames.
Mobility RSSI Threshold	Displays the RSSI threshold value of the parent to indicate fast roaming on a mobility mesh point.
Mobility Beacon Miss Number	Displays the number of consecutive missed beacon frames to indicate fast roaming on a mobility mesh point.

  wired-mac
```

Description

This command shows information for Aruba Air Monitors.

Parameter	Description
active-laser-beams	Show active laser beam generators. The output of this command shows a list of all APs that are actively performing policy enforcement containment such as rogue containment. This command can tell us which AP is sending out deauthorization frames, although it does not specify which AP is being contained.
ap-list	Show list of APs being monitored.
arp-cache	Show ARP cache of learned IP to MAC binding.
association	Show association table for an AP.
channel	Show state and stats of a specific channel.
client-list	Show list of client being monitored.
containment-info	Show containment events and counters triggered by the wired containment and wireless containment features configured in the ids general-profile . The output of this command shows device and target data for wired containment activity.

Parameter	Description
debug	Show the Air Monitor debugging information.
ids-state	Show IDS state.
mesh-list	Show list of mesh APs being monitored.
pot-ap-list	Display the potential AP table.
pot-client-list	Display the potential client table.
routers	Show Router MAC Addresses learned. The output of this command includes the router's MAC address, IP address and uptime.
scan-info	Show AP scanning information.
stats	Shows statistics for an AP or a client.
wired-mac	Show Wired MAC Addresses learned.

show ap monitor active-laser-beams

```
show ap monitor active-laser-beams {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows the active laser beam generators.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.
band <band>	Shows the radio band. Possible values are 2.4GHz, 5GHz, or 6GHz. NOTE: The 6GHz value is applicable to Wi-Fi 6E APs only.
channel <channel>	Shows the AP channel.

Example

The following example lists the active laser beam sources for a specific BSSID:

```
(host)[mynode] (config) #show ap monitor active-laser-beams bssid
f4:2e:7f:0b:a8:80
Active Laser Beam Sources
-----
bssid  channel  rssi  ap name  lms ip  master/ conductor ip  inactive time
-----
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The 6GHz value was added to <code>band <band></code> parameter for Wi-Fi 6E APs.
ArubaOS 8.0.0.0	Command introduced.

show ap monitor ap-list

```
show ap monitor ap-list
  ap-name <ap-name> {containment-exclusion} | {wifi-direct [ all ]} | {verbose}
  bssid <bssid>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command shows the list of APs being monitored.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
containment-exclusion	Shows details of vendor specific IE information for containment exclusion.
verbose	Shows additional information about flags and the flag, W is displayed to identify the Wi-Fi direct devices. This flag will be displayed only if the detection of WIFI-Direct P2P groups is enabled in the IDS unauthorized device profile.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example displays the Monitored AP table, which lists all the APs monitored by a specified AP or BSSID (For versions prior to ArubaOS 8.9.0.0).

```
(host) #show ap monitor ap-list ap-name all2

(*): Non-transmitted BSSID

```

The output of this command includes the following parameters:

Parameter	Description
bssid	BSSID of an AP. This is usually the AP's MAC address.
ssid	ESSID that names a wireless network.
chan (For versions prior to ArubaOS 8.9.0.0)	Radio channel used by the BSSID.
band/chan/ch-width/ht-type (ArubaOS 8.9.0.0 or later versions)	The AP radio type displayed as radio band/channel number/channel bandwidth/throughput type.
6Ghz capable (ArubaOS 8.9.0.0 or later versions)	Shows whether the AP supports 6 GHz radio band.

Parameter	Description
ap-type	Shows classification of the AP.
phy-type (For versions prior to ArubaOS 8.9.0.0)	Radio PHY type. Possible types include: <ul style="list-style-type: none"> ■802.11a ■802.11a-HT-40 ■802.11b/g ■802.11b/g-HT-20
dos	Shows if the feature to contain DoS attacks has been enabled or disabled.
dt/mt	dt: Detected time: the number of timer ticks since the AP was last detected. mt: Monitor time; the number of elapsed timer ticks since the AP first recognized the monitored AP.
ut/it	ut: Unseen time: the number elapsed timer ticks the monitored AP was not seen when scanning a channel of the device. it: AP idle time, the number of timer ticks since the AP last saw any frames from the monitored AP.
encr	Shows the encryption type of the BSSID. If there are multiple encryption types, this command shows the lowest encryption type.
nstas	Shows the number of stations connected to the AP (as seen by the monitoring AP).

Parameter	Description
avg-snr	Shows the average SNR.
curr-snr	Shows the current SNR.
avg-rssi	Shows the average RSSI for the device. NOTE: RSSI is an indication of the power level being received by the antenna. Therefore, the higher the RSSI number, the stronger the signal.
curr-rssi	Shows the current RSSI for the device.
wmacs	Shows the number of unique wireless MAC addresses seen on the Wi-Fi network from the AP's BSSID.
ibss	Shows all the monitored APs (BSSIDs).
cl-delay	Shows the delay in classification of each device. NOTE: The maximum delay for clients is not displayed if the <code>unclass_sta_update</code> parameter is not enabled.
bss-color	Shows the bss color selected. Range: 1-63
partial bss color	Shows if it is partial bss enabled.
bss color disabled	Shows if the bss color configuration is disabled.

The following example displays all the WIFI-Direct devices detected by a specified AP.

```
(host) #show ap monitor ap-list ap-name 635-ac wifi-direct all

Related Command

Command	Description
show ap monitor debug	This command shows information for an Air Monitor's current status, message counters, or profile settings.

Command History

Release	Modification
ArubaOS 8.11.1.0	A new sub-parameter, verbose was added to the show ap monitor ap-list ap-name <ap-name> command.
ArubaOS 8.11.0.0	The <code>containment-exclusion</code> and <code>wifi-direct[all]</code> sub-parameters were introduced.
ArubaOS 8.9.0.0	The command output was modified to include the following: <ul style="list-style-type: none"> Removed <code>chan</code> and <code>phy-type</code> parameters. Added <code>band/chan/ch-width/ht-type</code> and <code>6Ghz capable</code> parameters.
ArubaOS 8.0.0.0	Command introduced.

show ap monitor arp-cache

```
show ap monitor arp-cache {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|  
{ip6-addr <ip6-addr>}
```

Description

This command shows the ARP/NDP cache of learned IP to MAC bindings.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Examples

The following example shows the ARP/NDP cache table of learned IPv4 address:

```
(host) [mynode] (config) #show ap monitor arp-cache ip-addr 10.65.47.250  
  
br0:10.65.47.250

show ap monitor association

```
show ap monitor association {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows the association table for an Air Monitor (AM).

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example lists the MAC addresses associated with the Air Monitor BSSID (For versions prior to ArubaOS 8.9.0.0).

```
(host) #show ap monitor association ap-name ap9 00:1a:1e:11:74:a1
Association Table
-----
mac                rsta-type  auth  phy-type
---                -
00:1d:d9:01:c4:50  valid      yes   80211a
00:17:f2:4d:01:e2  valid      yes   80211a
00:1f:3b:8c:28:89  valid      yes   80211a
00:1d:d9:05:05:d0  valid      yes   80211a
00:14:a4:25:72:6d  valid      yes   80211a
00:19:7d:d6:74:8d  valid      yes   80211a
```

The output of this command includes the following parameters:

Column	Description
mac	MAC address associated with the Air Monitor BSSID

Column	Description
<pre>rsta-type</pre>	Rogue station type: <ul style="list-style-type: none"> ■ interfering: Interfering station. ■ valid: Station is not a rogue station. ■ DoS: Station may have attempted a DoS attack.
<pre>auth</pre>	Displays a yes if the client has been authenticated.
<pre>phy-type</pre> (For versions prior to ArubaOS 8.9.0.0)	The RF band in which the AP should operate: <ul style="list-style-type: none"> ■ 802.11g = 2.4 GHz ■ 802.11a = 5 GHz
<pre>band</pre> (For ArubaOS 8.9.0.0 or later versions)	The RF band in which the AP should operate. Displays one of the following values: <ul style="list-style-type: none"> ■ 2.4GHz ■ 5GHz ■ 6GHz(For Wi-Fi 6E APs)

Related Command

Command	Description
am	The <code>scan</code> sub-command enables channel scanning for the specified air monitor. In addition, the <code>test</code> sub-command enables the client to test an air monitor.

Command History

Release	Modification
ArubaOS 8.9.0.0	<p>The command output was modified to display the following changes (For ArubaOS 8.9.0.0 or later versions):</p> <ul style="list-style-type: none"> ■ Replaced <code>phy-type</code> with <code>band</code> ■ Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values for <code>band</code> output parameter respectively. ■ Introduced 6GHz value for <code>band</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

show ap monitor containment-info

```
show ap monitor containment-info {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows the AP containment activity.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The output of the command lists the wired containment counters for a BSSID:

```
(host) *[mynode] (config) #show ap monitor containment-info bssid ac:a3:1e:57:82:40
```

```
wifi0: Wireless Containment Counters

```

Description

This command shows information for an Air Monitor's current status, message counters, or profile settings.

Parameter	Description
counters	Shows the maximum classification delay that was observed in monitored APs and clients, the number of Unclassified Device messages that were sent to the WMS, and the number of monitored APs/clients that were present in those messages. This parameter also shows the number of monitored APs/clients that were created and removed by the AP. This information is captured on an hourly basis for the last 24 hours. NOTE: The maximum delay for clients is not displayed if the unclass_sta_update parameter is not enabled.
profile-config	Shows the configuration received by the AP for each profile.
status	Shows general AP status information and the maximum classification delay that was observed in monitored APs and clients, in the WLAN Interface option. NOTE: The maximum delay for clients is not displayed if the unclass_sta_update parameter is not enabled.
ap-name <ap-name>	Show data for an AM with a specific name.
bssid <bssid>	Show data for an AM with a specific BSSID. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AM with a specific IP address by entering its IPv4 address in dotted-decimal format.

Parameter	Description
ip6-addr <ip6-addr>	Show data for an AM with a specific IP address by entering its IPv6 address in dotted-decimal format.
am-scan	Show Air Monitor active scanning configuration.
ap-radio	Show the Air Monitor radio configuration parameters, as defined in the AM's 802.11a, 802.11b, or high-throughput radio profiles.
ap-system	Show an Air Monitor's system configuration settings, as defined in its AP System profile.
arm	Show an Air Monitor's ARM settings, as defined in its current ARM profile
event-thresholds	Show an Air Monitor Event Thresholds settings, as defined in its current RF Event Thresholds profile
ids-dos	Show an Air Monitor IDS DoS settings, as defined in its current IDS DoS profile.
ids-general	Show an Air Monitor IDS General Configuration settings, as defined in its IDS General profile.
ids-impersonation	Show an Air Monitor IDS Impersonation Configuration settings, as defined in its IDS Impersonation profile.
ids-signature-matching	Show an Air Monitor IDS Signature Matching configuration settings, as defined in its IDS Signature Matching profile
ids-unauthorized-device	Show an Air Monitor IDS Unauthorized Device configuration settings, as defined in its IDS Unauthorized Device profile.
interference	Show an Air Monitor's interference configuration settings, as defined in its current RF Optimization profile.
regulatory-domain	Show an Air Monitor's Regulatory Domain configuration settings, as defined in its Regulatory Domain profile.
rf-behavior	Show an Air Monitor RF Behavior Configuration

Examples

The output of the following command includes the *WLAN Interface*, *Data Structures*, *WLAN InterfaceSwitch Status* and *RTLS Configuration* tables for the specified AP.

The output of this command includes the following parameters:

Column	Description
bssid	BSSID for the AP. This is usually the AP's MAC address.
scan	Indicates whether or not if active scanning is enabled on this AP.
monitor	Indicates whether the AP radio is currently enabled or disabled.
probe-type	This parameter displays one of the following options to show the AP is configured. <ul style="list-style-type: none"> ■ sap: Default AP setting. ■ am: AP is configured as an Air Monitor. ■ m-portal: AP is configured as a Mesh portal. ■ m-point: AP is configured as a Mesh point. ■ airmatch-am: AP is configured in AP monitoring mode.
task	This parameter displays one of the following options to show the radio's current task: <ul style="list-style-type: none"> ■ scan: AP is scanning other channels. ■ tuned: AP is tuned on one channel. ■ locate: AP has been asked to locate a specific AP or client. ■ pcap: The AP is enabled with the Packet Capture feature.
channel	The radio channel currently used by an AP's WLAN interface.
pkts	Number of packets seen on the interface.

Column	Description
mac	MAC address for the AP's wired interface.
ip	The AP's IP address.
gw-ip	IP address for the AP's gateway.
gw-mac	MAC address for the AP's gateway.
status	Shows if the interface is currently enabled or disabled.
pkts	Number of packets seen on the AP's wired interface.
macs	Number of MAC addresses in the Wired MAC table for that interface.
gw-macs	Number of MAC addresses in the Wired MAC table for that interface.
tagged-pkts	Number VLAN-tagged packets sent to that interface.
vlan	The VLAN ID for the packets sent to that interface.
Packets read	Number of packets read by the AP since it was last reset.
Bytes read	Number of bytes read by the AP since it was last reset.
Num Intercepts	Number of interrupts from the AP's driver.
Num Buffer Overflows	Number of times excessive traffic has filled the AP's buffers.
Max PPS	Maximum throughput rate seen on the interface, in packets per second.
Cur PPS	Current throughput rate seen on the interface, in packets per second.
Max PPI	Maximum interrupt rate seen on the interface, in interrupts per second.
Cur PPI	Current interrupt rate seen on the interface, in interrupts per second.
Uptime	Number of seconds since the AP was last reset.
LMS IP	IP address of the AP's managed device
Master/Conductor IP	IP address of the AP's Mobility Conductor.
AP type	AP model type.

Column	Description
Country Code	The AP's country code. Valid radio channels for your wireless network are based on your country code. If you change the AP's country code, the valid channels will be reset to the defaults for the new country.
ap	Number of other APs monitored by this AP.
sta	Number of clients and APs seen by this AP.
pap	Number of potential APs; APs which have transmitted a beacon, but have not yet been registered.
psta	Number of potential stations; AP has seen a MAC address from the station but hasn't yet received traffic from it.
ch	Number of channel entries in the channel table.
msg-hash	Number of different message types seen on the interface.
ap-1	(For internal use only)
WMS on Master/Conductor	Indicates if the AP communicates to the wms process on Mobility Conductor or a managed device. enabled: Communicates with Mobility Conductor. disabled: Communicates with a managed device only.
Stats Update Interval	If the AP is collecting statistics, this value is the interval in seconds in which the AP sends statistics to the WMS process.
Poll Interval	Interval, in milliseconds, that the AP sends RSSI updates to the WMS process.
Num Switches	Number of controllers to which this AP has access. If the value is 1, the AP has access to Mobility Conductor <i>or</i> a managed device. If the value is 2, the AP has access to Mobility Conductor <i>and</i> a managed device.
Collect Stats	If enabled, the AP will collect statistics to send to the WMS process.
Bssid	BSSID of the radio.
Type	Indicates whether the controller type is master (Mobility Conductor) or local (managed device).
Status	If up , the AP can reach the managed device. If down , the AP cannot reach the managed device.
Last-reg	The time the AP last registered with the WMS process.
N-reg	Number of times the AP has registered with the WMS process.

Column	Description
Last-update	The last timer tick time the AP updated the WMS process.
Next-update	Interval between the last update and the next scheduled update.
N-updates	Number of updates sent to the WMS process.
Last-ack	Number of timer ticks since the AP received an acknowledgment from the WMS process.
Type	Type of RTLS server used by the AP, such as MMS or Aeroscout.
Server IP	IP address of the RTLS server.
Port	Port used by the RTLS server.
Frequency	Rate, in seconds, at which RTLS messages are sent to the server.
Active	Indicates if the server is active on the AP.
Rpt-Tags	Displays whether tag reporting is enabled or not.
Tag-Mcast-Addr	Displays MAC OUI of the tags that are forwarded to the server.
Tags-Sent	Displays the cumulative count of the tag reports sent to server.
Rpt-Sta	Displays whether station reporting is enabled or not.
Incl-Unassoc-Sta	Displays whether unassociated stations are included in station reporting or not.
Sta-Sent	Displays cumulative count of station reports sent to server.
Cmpd-Msgs-Sent	Displays cumulative count of compound messages containing station reports sent to server.

Starting from ArubaOS 8.11.0.0, the output of the `show ap monitor debug status` command includes new counters that list discarded and detected Apple Wireless Direct Link (AWDL) frames.

```

AM AWDL Counters (wifi0)
-----
Parameter                Value
-----
Dropped AWDL frames      0
Detected AWDL frames     1171

```

The output of this command includes the following parameters:

Column	Description
Parameter	Type of Apple Wireless Direct Link frame.
Value	Number of Apple Wireless Direct Link frames that are dropped or detected.

show ap monitor ids-state

```
show ap monitor ids-state {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|  
{ip6-addr <ip6-addr>}  
    block-ack|dsta|events|general|mac-oui|mitm|omerta|ps-  
    dos|rate|sequence|signature|spoofed-frames|valid-ssid|wpa-ft
```

Description

This command shows the IDS state for AP monitor.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
block-ack	Show current sequence number windows for block ACKs.
dsta	Show deauth station monitoring state.
events	Show most recent IDS events.
general	Show general IDS configuration.
mac-oui	Show MAC OUI tables.
mitm	Show statistics that are being monitored to detect channel based Man in the Middle.
omerta	Show statistics that are being monitored to detect Omerta attack.
ps-dos	Show statistics that are being monitored to detect Power Save DoS attack.
rate	Show rate check state.
sequence	Show sequence analysis state.
signature	Show signature state.
spoofed-frames	Show count of frames that were spoofed to look as if they were from VAPs on this AP.
valid-ssid	Show valid and protected SSIDs.
wpa-ft	Show WPA FT Attack Detection state.

Example

The following example shows the deauth station monitoring state table:

```
(host) [mynode] (config) #show ap monitor ids-state bssid ac:a3:1e:57:82:52
dsta

 35   3   disable  31   64
```

The output of this command includes the following information:

Column	Description
bssid	The Basic Service Set Identifier of the AP.
channel (For versions prior to ArubaOS 8.9.0.0)	The current radio channel of the AP.
phy (For versions prior to ArubaOS 8.9.0.0)	The radio's PHY type. Possible values are 802.11a, 802.11a-HT-40, 802.11b/g, 802.11b/g-HT-20.
band/chan (For ArubaOS 8.9.0.0 or later versions)	The current radio channel and RF band type.
num-beacons	Number of beacons seen during a 10-second scan.
tot-beacons	Total number of beacons seen since the last reset.
num-frames	Total number of frames seen since the last rest.
mt	Monitor time; the number of timer ticks elapsed since the controller first recognized the AP.
it	Idle time - expressed as a number of timer ticks.

Column	Description
at	Active time, in timer ticks.
ibss	Shows if adhoc BSS is enabled or disabled. It will be enabled if the BSSID has detected an adhoc BSS (an ibss bit in an 802.11 frame).
snr	Signal-to-Noise ratio.
rssi	The Receive Signal Strength Indicator (RSSI) value that represents signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.

Command History

Release	Modification
ArubaOS 8.9.0.0	The command output was modified to display the following changes (For ArubaOS 8.9.0.0 or later versions): <ul style="list-style-type: none"> ■ Replaced <code>channel</code> and <code>phy</code> with <code>band/chan</code> parameter. ■ Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values for <code>band/chan</code> output parameter respectively. ■ Introduced 6GHz value for <code>band/chan</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

show ap monitor pot-client-list

```
show ap monitor pot-client-list {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows potential client list being monitored.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example shows the potential client table (For versions prior to ArubaOS 8.9.0.0):

```
(host) [mynode] (config) #show ap monitor pot-client-list bssid
1d:b3:1e:57:17:20

show ap monitor routers

```
show ap monitor routers {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|  
{ip6-addr <ip6-addr>}
```

Description

This command shows the router MAC addresses learned.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example lists the wired MAC addresses or potential wireless devices:

```
(host) [mynode] (config) #show ap monitor routers bssid cd:a9:1e:57:28:98  
  
Wired MAC of Potential Wireless Devices

show ap monitor scan-info

```
show ap monitor scan-info {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|  
{ip6-addr <ip6-addr>}
```

Description

This command shows the AP scanning information.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example lists the AP scanning information:

show ap monitor stats

```
show ap monitor stats {advanced}|{ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows packet, signal, and channel statistics for an AP or a client.

Parameter	Description
advanced	Show advanced statistics for an AP or client.
ap-name <ap-name>	Show statistics for an AP with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show data for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example shows monitoring statistics for the AP ap305, and a client with the MAC address d8:6c:02:99:bc:7a:

```
(host) #show ap monitor stats ap-name ap305 mac d8:6c:02:99:bc:7a verbose

```

The output of this command includes the following parameters:

Column	Description
retry	Percent of 802.11 retry frames sent because a client failed to send an ACK.
Low-speed	Percent of frames sent at a data rate of 18 Mbps or slower.
non-unicast	Percent of non-unicast frames
recev-error	Percent of error frames of all frames seen in the last second.
frag	Rate of fragmented packets, in frames per second

Column	Description
bwth	Current bandwidth, in bps.
avg-signal	Average signal-to-noise ratio over the interval since the AP's last reset.
low-signal	Lowest signal-to-noise ratio over the interval since the AP's last reset.
high-signal	Highest signal-to-noise ratio over the interval since the AP's last reset.
count	Number of packets seen on the AP over the interval since the AP's last reset.
Duration	Time over which the AP has measured RSSI values.
tx	The total number of deauthorization frames sent to this MAC address for containment in the interval from the AP's last reset until the current timer tick.
old-tx	The total number of deauthorization frames sent to this MAC address for containment until the previous timer tick.
rx	The total number of deauthorization frames spoofing the MAC address in the interval from the AP's last reset until the current timer tick.
old-rx	The total number of deauthorization frames sent to this MAC address for containment until the previous timer tick.
FRR	Frame retry rate, in frames per second.
FRER	Frame error retry rate, in frames per second.
rss-index	This value indicates the number of consecutive timer ticks over which the value of the RSSI of the client has reduced by more than 3 units. NOTE: This value is updated only if 'handoff-assist' is enabled in the AP's RF Optimization profile.
cur-signal	The RSSI of the most recent frame received from the specified MAC address.
old-cur-signal	The most recent RSSI of the MAC which is 3 lower or 5 higher than the current RSSI. NOTE: This value is updated only if 'handoff-assist' is enabled in the AP's RF Optimization profile
ht-type	This parameter indicates support for the following HT types:

Column	Description
	no : No support for high-throughput. HT-20 : Support for 20 Mhz high-throughput only. HT-40 : Support for 40 Mhz high-throughput.
primary-channel	Primary radio channel.
sec-channel	Secondary radio channel
gf-supported	If 1 , this AP supports greenfield mode. If 0 , greenfield is not supported.
40mhz-intolerance	Indicates whether the specified MAC address is 40 Mhz intolerant.

Related Commands

Command	Description
show ap monitor debug	This command shows information for an Air Monitor's current status, message counters, or profile settings.
show ap monitor	This command shows information for Aruba Air Monitors.

Command History

Release	Modification
ArubaOS 8.4.0.0	The output of the <code>show ap monitor stats</code> command was modified to display the additional debug counter information.
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

show ap monitor wired-mac

```
show ap monitor wired-mac {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|  
{ip6-addr <ip6-addr>}  
ap-bssid|config|enet-mac|gw-mac|oui-prop|system-gw-mac|system-wired-mac
```

Description

This command shows the wired MAC addresses learned.

Parameter	Description
ap-name <ap-name>	Shows data for an AM with a specific name.
bssid <bssid>	Shows data for an AM with a specific BSSID. The BSSID is usually the AM's MAC address.
ip-addr <ip-addr>	Shows data for an AM with a specific IPv4 address by entering its IPv4 address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AM with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.
ap-bssid	Specify BSSID of monitored AP.
config	Display Configured Wired MACs.
enet-mac	Display wired MACs learned at AM ENET Interface.
gw-mac	Display Gateway MACs learned at AM ENET Interface.
oui-prop	Display OUI propagation information.
system-gw-mac	Display gateway MACs learned at the controller.
system-wired-mac	Display wired MACs learned at the controller.

Example

The following example shows the wired MAC address table:

```
(host) [mynode] (config) #show ap monitor wired-mac bssid ac:a3:1e:57:82:52  
ap-bssid ac:a3:1e:57:82:52
```

Related Command

Command	Description
ap multizone-profile	MultiZone feature allows AP to terminate to multiple managed devices that reside in different zones. A zone is a collection of managed devices under a single administration domain. The zone can have a single managed device or a cluster. This command allows you to create an AP MultiZone profile, set the data zone index, and controller-ip.

Command History

Release	Modification
ArubaOS 8.4.0.0	The output of the <code>show ap multizone-profile</code> command was modified to display the IPv6 Address and Description columns.
ArubaOS 8.0.1.0	The <code>num-nodes</code> sub-parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on managed devices.

show ap owe-tm-info

```
show ap owe-tm-info
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
  wired-mac <wired-mac>
```

Description

This command shows information about OWE Transition VAPs generated.

Parameter	Description
ap-name <ap-name>	Shows OWE Transition VAPs generated on the AP with this name.
ip-addr <ip-addr>	Shows OWE Transition VAPs generated on the AP with IPv4 address.
ip6-addr <ip6-addr>	Shows OWE Transition VAPs generated on the AP with IPv6 address.
wired-mac <wired-mac>	Shows OWE Transition VAPs generated on the AP with MAC address.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Configuration mode on Mobility Conductor.

show ap packet-capture

```
show ap packet-capture status {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

Description

This command shows the status of outstanding packet capture (pcap) sessions. The Packet Capture (pcap) feature copies control path packets from the Aruba Control Processor, providing visibility for packets to or from the controller. This provides a useful troubleshooting tool for diagnosing communication problems with elements such as a Radius server. You can retrieve these packets by issuing the command `tar logs`, and then viewing the file `filter.pcap` on the controller's flash drive.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.

Example

The following example shows the Packet Capture Sessions table for an AP named **AP16**:

```
(host) #show ap packet-capture status ap-name AP16
Packet Capture Sessions
-----
pcap-id  filter  type  intf          channel max-pkt-size  num-pkts
status   url    target
-----  -
1         raw    00:1a:1e:82:ab:b0  161
```

The output of this command includes the following parameters:

Column	Description
pcap-id	ID number of the packet capture session.
filter	Packet Capture filter specification.

Column	Description
type	A raw packet capture type indicates that the controller is streaming raw packets to an external viewer.
intf	BSSID of the interface for the PCAP session.
channel	Channel used by AP to capture packets.
max-pkt-size	Maximum size of all captured packets.
num-pkts	Number of packets captured during the session.
status	Shows the current status of the packet-capture session.
url	Packet capture data can be downloaded to this URL.
target	IP address of the client station running Wildpacket's AiroPeek monitoring application.

Related Command

Command	Description
packet-capture	Use this command to enable or disable packet capturing and set packet capturing options for a single packet capture session.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show ap papi-err

```
show ap papi-err {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command shows the PAPI error messages.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show data for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following example displays the status of PAPI send error messages:

```
(host) #show ap papi-err
STM SAP PAPI Send Error
-----
Name  bssid  ip   Tunnel Add  Tunnel Remove  Arp Req  Vlan Req  Sta Req
Mcast Req
-----
-----
```

Related Command

Command	Description
papi-security	This command enforces advanced security options and provides an enhanced level of security. It allows to enable or disable the PAPI Enhanced Security configuration and to configure a new security key if required.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show ap port status

```
show ap port status {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>|wired-mac <wired-mac>}
```

Description

This command shows the status of the AP's wired ports. The status is updated every 60 seconds.

Parameter	Description
ap-name <ap-name>	Name of the AP.
bssid <bssid>	BSSID of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
wired-mac <wired-mac>	MAC address of the AP.

Example

The following example shows the wired port status of an AP named **LocalAP1**. In this example, the output is divided into multiple sections to fit better on the pages of this document. In the actual CLI, it appears in a single long table.

```
(host) #show ap port status ap-name LocalAP1

AP "LocalAP1" Port Status (updated every 60 seconds)

show ap profile-usage

```
show ap profile-usage {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>}
```

Description

This command shows a complete list of all profiles referenced by an individual AP or an AP BSSID. Use this command to monitor the configuration profiles in use by an AP or a specific BSSID. The output of this command shows the name of each profile type that is associated with the AP or BSSID, as well as the source that associates the profile with the AP.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. The BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address by entering its IP address in dotted-decimal format.

Example

The following example shows the list of all profiles associated with the AP or BSSID:

show ap provisioning

```
show ap provisioning {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}|{wired-mac <wired-mac>}
```

Description

This command shows provisioning parameters currently used by an AP.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific BSSID on an AP. An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IPv4 address.
ip6-addr <ip6-addr>	Show data for an AP with a specific IPv6 address.
wired-mac <wired-mac>	Show data for an AP with a specific MAC address.

Example

The following example shows that the AP named AP8 has mostly default parameters. These appear with the value N/A.

```

The output of this command includes the following parameters:

Column	Description
AP Name	Name of the AP.
AP Group	AP group to which the AP belongs.
Location name	FQLN for the AP.
SNMP sysLocation	User-defined description of the location of the AP, as defined with the command provision-ap syslocation.
Master/Conductor	Name or IP address for Mobility Conductor.
Gateway	IP address of the default gateway for the AP.
Netmask	Netmask for the AP's IP address.
IP Addr	IP address for the AP.
IPv6	The static IP6 address of the AP.6

Column	Description
IPv6 Prefix	The prefix of static IPv6 address of the AP.
Dns IP	IP address of the DNS server.
DNS IPv6	The prefix of static IPv6 address of the AP.
Domain Name	Domain name used by the AP.
Server Name	DNS name of the managed device from which the AP boots.
Server IP	IP address of the managed device from which the AP boots
Antenna gain for 802.11a	Antenna gain for 802.11a (5GHz) antenna.
Antenna gain for 802.11g	Antenna gain for 802.11g (2.4GHz) antenna.
Antenna for 802.11a	Antenna use for 5 GHz (802.11a) frequency band. <ul style="list-style-type: none"> ■ 1: AP uses antenna 1 ■ 2: AP uses antenna 2 ■ both: AP uses both antennas
Antenna for 802.11g	Antenna use for 2.4 GHz (802.11g) frequency band. <ul style="list-style-type: none"> ■ 1: AP uses antenna 1 ■ 2: AP uses antenna 2 ■ both: AP uses both antennas
Single chain mode for Radio 0	If this parameter is set to 1 for an 802.11n-capable radio, the radio will operate in single-chain mode, and will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This parameter is set to 0 (disabled) by default.
Single chain mode for Radio 1	If this parameter is set to 1 for an 802.11n-capable radio, the radio will operate in single-chain mode, and will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This parameter is set to 0 (disabled) by default.
IKE PSK	IKE PSK The IKE pre-shared key.
PAP password	Password Authentication Protocol (PAP) password for the AP.
PAP User Name	PAP username for the AP.
PPPOE User Name	Point-to-Point Protocol over Ethernet (PPPoE) user name for the AP.
PPPOE Password	PPPoE password for the AP.
PPPOE Service Name	PPPoE service name for the AP.

Column	Description
PPPOE CHAP secret	PPPoE CHAP secret key for the AP.
USB User Name	The PPP username provided by the cellular service provider
USB Password	A PPP password, if provided by the cellular service provider
USB Type	The USB driver type.
USB Device Identifier	The USB device identifier.
USB Dial String	The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.
USB Initialization String	The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct.
USB TTY device data path	The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.
USB TTY device control path	The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.
Uplink VLAN	If you configured an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink. By default, an AP has an uplink vlan of 0, which disables this feature.
Link Priority Ethernet	Set the priority of the wired uplink, from 0-255. Each uplink type has an associated priority; wired ports having the highest priority by default.
Link Priority Cellular	The priority of the cellular uplink, from 0-255. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link.
Mesh Role	If the mesh role is "none," the AP is operating as a thin AP. An AP operating as a mesh node can have one of two roles: mesh portal or mesh point.
Installation	Indicates the type of installation (indoor or outdoor). The <code>default</code> parameter indicates that the installation mode is determined by the AP model type.
Latitude	Latitude coordinates of the AP, in the <i>Degrees Minutes Seconds</i> (DMS) format.
Longitude	Longitude coordinates of the AP, in the <i>Degrees Minutes Seconds</i> (DMS) format.

Column	Description
Altitude	Altitude, in meters, of the AP. This parameter is supported on outdoor APs only.
Antenna bearing for 802.11a	Horizontal coverage distance of the 802.11a (5GHz) antenna from true north, from 0-360 degrees. NOTE: This parameter is supported on outdoor APs only. The horizontal coverage pattern does not consider the elevation or vertical antenna pattern.
Antenna bearing for 802.11g	Horizontal coverage distance of the 802.11g (2.4GHz) antenna from true north, from 0-360 degrees. NOTE: This parameter is supported on outdoor APs only. The horizontal coverage pattern does not consider the elevation or vertical antenna pattern.
Antenna tilt angle for 802.11a	The angle of the 802.11a (5GHz) antenna. This parameter can range from between -90 degrees and 0 degrees for downtilt, and between +90 degrees and 0 degrees for uptilt.
Antenna tilt angle for 802.11g	The angle of the 802.11g (2.4GHz) antenna. This parameter can range from between -90 degrees and 0 degrees for downtilt, and between +90 degrees and 0 degrees for uptilt.
Mesh SAE	Shows if the AP has enabled or disabled Secure Attribute Exchange (SAE) on a mesh network.

Related Commands

Command	Description
provision-ap	Change provisioning parameters for an individual AP. This command does not save the provisioning parameters settings in a reusable profile.

show ap provisioning-profile

```
show ap provisioning-profile [<profile-name>]
```

Description

This command shows information for AP provisioning profiles. The AP provisioning profile allows you to define a set of provisioning parameters to an AP group. These settings can be saved or assigned to an AP group via the command `ap-group <group> provisioning-profile <profile>`.

Issue this command without the **<profile-name>** option to display the entire AP provisioning profile list, including profile status and the number of references to each profile. Include a profile name to display the authorization group defined for that profile.

Parameter	Description
<profile-name>	The name of an existing AP provisioning profile.

Examples

The following example lists all AP provisioning profiles. The **References** column lists the number of other profiles with references to that provisioning profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined AP provisioning profiles will not have an entry in the **Profile Status** column.

```
(host) [mynode] #show ap provisioning-profile

Provisioning profile List
-----
Name       References  Profile Status
----       -
default    12
outdoor    3
```

To display the configuration settings for an individual profile, include the <profile> parameter. The following example shows the profile details for the AP provisioning profile **Default**:

```
(host) [mynode] #show ap provisioning-profile default

Provisioning profile "default"
-----
Parameter                                     Value
-----
Remote-AP                                     No
```

```

Master/Conductor IP/FQDN

AP POE Power optimization false
Master/Conductor Preference
IPv4

```

The output of this command includes the following parameters:

Parameter	Description
Remote-AP	Indicates that the profile is associated with a remote AP using certificates.
Master/Conductor IP/FQDN	The FQDN or IP address for Mobility Conductor.
PPPOE User Name	PPPoE username for the AP.
PPPOE Password	PPPoE password for the AP.
PPPOE Service Name	PPPoE service name for the AP.

Parameter	Description
USB User Name	The PPP username provided by the cellular service provider
USB Password	A PPP password, if provided by the cellular service provider
USB Device Type	The USB driver type.
USB Device Identifier	The USB device identifier.
USB Dial String	The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.
USB Initialization String	The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct.
USB TTY device data path	The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.
USB TTY device control path	The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.

Parameter	Description
USB modeswitch parameters	All the parameters that is required to be passed to the USB mode switch utility.
Link Priority Ethernet	Set the priority of the wired uplink, from 0-255. Each uplink type has an associated priority; wired ports having the highest priority by default.
Link Priority Cellular	The priority of the cellular uplink, from 0-255. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link.
Cellular modem network preference	Multi-mode cellular modem network preference type.
Username of AP so that AP can authenticate to 802.1X using PEAP	If your AP uses PEAP authentication, this field displays the AP username.
Password of AP so that AP can authenticate to 802.1X using PEAP	If your AP uses PEAP authentication, this field displays the AP password.
Enable AP to 802.1x using EAP-TLS	Enables AP to perform 802.1x authentication using EAP-TLS.

Parameter	Description
Enable AP to use factory certificates when doing 802.1x EAP-TLS	Enables AP to use the factory certificates to perform 802.1x EAP-TLS authentication.
AP dot1x EAP-TLS username suffix	Enables AP to use EAP-TLS username suffix.
AP dot1x EAP-TLS username suffix domain	Sets the suffix domain for AP dot1x EAP-TLS username. If defined, use EAP-TLS username as suffix, else use aruba.ap .
Uplink VLAN	If you configured an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink. By default, an AP has an uplink vlan of 0, which disables this feature.
USB power mode	The USB power mode to control the power to the USB port.
AP POE Power optimization	Displays the AP POE power optimization status.
Master/Conductor Preference	Displays the preferred IP protocol for AP master /conductor discovery.

Related Command

Command	Description
provision-ap	Change provisioning parameters for an individual AP. This command does not save the provisioning parameters settings in a reusable profile.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .
ArubaOS 8.7.0.0	The <code>Master Preference</code> parameter was added to the output of the <code>show ap-provisioning profile</code> command.
ArubaOS 8.4.0.0	The following parameters were added to the output of the <code>show ap-provisioning profile</code> command: <ul style="list-style-type: none">■ <code>AP dot1x EAP-TLS username suffix</code>■ <code>AP dot1x EAP-TLS username suffix domain</code>■ <code>USB power mode</code>
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap provisioning-rule

```
show ap provisioning-rule [<profile-name>]
```

Description

This command displays information for an AP provisioning rule. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
<profile-name>	The name of an existing AP provisioning rule.

Example

The following example shows the details of the conditions and actions for the AP provisioning rule: **test**:

```
(host) [mm] (config) #show ap provisioning-rule test

ap provisioning rule "test"
-----
Parameter                               Value
-----
ip range                                 N/A
network                                 3.3.3.3/1
any AP                                   false
AP Type                                  AP-UNKNOWN
ap group                                  N/A
Antenna gain for 802.11g                 N/A
Antenna gain for 802.11a                 N/A
Radio 0 5GHz Antenna gain for APs support Dual 5GHz mode N/A
Radio 1 5GHz Antenna gain for APs support Dual 5GHz mode N/A
```

The output of this command includes the following parameters:

Parameter	Description
ip range	Indicates the IPv4 or IPv6 address range to check if the IP address of the AP is within this range.

Parameter	Description
network	Specifies the IPv4 or IPv6 network address to check if the IP address of the AP is within this network address.
any AP	Indicates if you want to apply the provisioning rule's condition to any AP.
AP Type	Indicates the AP model to apply the rule to this particular AP.
ap group	Indicates the AP group that you want to assign to the AP.
Antenna gain for 802.11g	Indicates the antenna gain for 802.11g (2.4 GHz) antenna.
Antenna gain for 802.11a	Indicates the antenna gain for 802.11a (5 GHz) antenna.
Radio 0 5GHz Antenna gain for APs support Dual 5GHz mode	Antenna gain for radio 0 (5 GHz) antenna. This parameter is only displayed for APs that support dual 5 GHz mode.
Radio 1 5GHz Antenna gain for APs support Dual 5GHz mode	Antenna gain for radio 1 (5 GHz) antenna. This parameter is only displayed for APs that support dual 5 GHz mode.

Related Command

show ap radio-database

```
show ap radio-database
  band [a|g] (For versions prior to ArubaOS 8.9.0.0)
  band [2.4GHz|5GHz|6GHz] (ArubaOS 8.9.0.0 or later versions)
  group <group>
  mode [access-point|air-monitor|disabled|ht|ht-40mhz|legacy|sap-monitor]
  page <page>
  sort-by [ap-group|ap-ip|ap-name|ap-type|switch-ip]
  sort-direction [ascending|descending]
  start <start>
  switch <switch-ip-addr>
```

Description

Show radio information for Access Points visible to this controller.

Parameter	Description
band	Show only APs with a radio operating in the specified band.
a (For versions prior to ArubaOS 8.9.0.0)	Show only APs with a radio operating in the 802.11a band (5 GHz).
g (For versions prior to ArubaOS 8.9.0.0)	Show only APs with a radio operating in the 802.11g band (2.4 GHz).
2.4GHz (ArubaOS 8.9.0.0 or later versions)	Show only APs with a radio operating in the 2.4 GHz band.
5GHz (ArubaOS 8.9.0.0 or later versions)	Show only APs with a radio operating in the 5 GHz band.
6GHz (ArubaOS 8.9.0.0 or later versions)	Show only APs with a radio operating in the 6 GHz band.
group <group>	Show only APs associated with the specified AP group.
mode	Show only APs with a radio operating in the specified mode.
access-point	Show only APs operating as access points.
air-monitor	Show only APs operating as air monitors.
disabled	Show only disabled APs.
ht	Show only high-throughput APs.

Parameter	Description
ht-40mhz	Show only 40 Mhz high-throughput APs.
legacy	Show only legacy (not high-throughput) APs.
sap-monitor	Show only APs operating as SAP monitors.
page <page>	Shows the number of APs.
sort-by	Sort the output of this command by a specific data column.
ap-group	Sort the output of this command by AP group name.
ap-ip	Sort the output of this command by AP IP address.
ap-name	Sort the output of this command by AP name.
ap-type	Sort the output of this command by AP model type.
switch-ip	Sort the output of this command by controller ip address.
sort-direction	Select a sort direction for the output of this command.
ascending	Sort the output in ascending order.
descending	Sort the output in descending order.
start	Start displaying the output of this command at a chosen index number by entering the index number of the AP at which command output should start.
switch <switch-ip-addr>	Display information for APs associated with a specific controller by entering the IP address of that controller.

Example

The following example shows the radio information for APs (For versions prior to ArubaOS 8.9.0.0).

```
(host) #show ap radio-database
AP Radio Database
```

```

-----
Name          Group      AP Type  IP Address  Status      Flags  Switch

Total APs:11

```

The output of this command includes the following parameters:

Column	Description
Name	Name of the AP.
Group	AP group to which the AP is associated.
AP Type	AP model type.
IP address	IP address of the AP.
Status	Current AP status. If the AP is currently up, this data column also shows the amount of time for which the AP has been active.
Flags	This column displays a letter that corresponds to some type of additional information for the AP. The key to the list of possible flags appears at the bottom of the output of this command.
Switch IP	IP address of the AP's controller.
Standby IP (ArubaOS 8.9.0.0 or later versions)	Standby IP address of the AP's controller.
Radio 0 Band Ch/EIRP/MaxEIRP/Clients 8.9.0.0) (For versions prior to ArubaOS	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 0.

Column	Description
Radio 1 Band Ch/EIRP/MaxEIRP/Clients 8.9.0.0) (For versions prior to ArubaOS	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 1.
Radio 2 Band Ch/EIRP/MaxEIRP/Clients 8.9.0.0) (For versions prior to ArubaOS	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 2.
Radio 0 Band/Chan/HT-Type/EIRP (ArubaOS 8.9.0.0 or later versions)	Radio ID, band, channel, high-throughput traffic type, and EIRP of Radio 0.
Radio 1 Band/Chan/HT-Type/EIRP (ArubaOS 8.9.0.0 or later versions)	Radio ID, band, channel, high-throughput traffic type, and EIRP of Radio 1.
Radio 2 Band/Chan/HT-Type/EIRP (ArubaOS 8.9.0.0 or later versions)	Radio ID, band, channel, high-throughput traffic type, and EIRP of Radio 2.

Command History

Command	Description
ArubaOS 8.9.0.0	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ■ Replaced <code>band [a g]</code> with <code>band [2.4GHz 5GHz 6GHz]</code> parameters (ArubaOS 8.9.0.0 or later versions). ■ Replaced <code>Radio 0 Band Ch/EIRP/MaxEIRP/Clients</code> with <code>Radio 0 Band/Chan/HT-Type/EIRP</code> in the output parameter (ArubaOS 8.9.0.0 or later versions). ■ Replaced <code>Radio 1 Band Ch/EIRP/MaxEIRP/Clients</code> with <code>Radio 1</code>

Command	Description
	<p>Band/Chan/HT-Type/EIRP in the output parameter (ArubaOS 8.9.0.0 or later versions).</p> <ul style="list-style-type: none"> ■ Replaced Radio 2 Band <p>Ch/EIRP/MaxEIRP/Clients with Radio 2</p> <p>Band/Chan/HT-Type/EIRP in the output parameter (ArubaOS 8.9.0.0 or later versions).</p>
ArubaOS 8.6.0.0	<p>A new output parameter Radio 2 Band</p> <p>Ch/EIRP/MaxEIRP/Clients was introduced for AP-555 access points.</p>
ArubaOS 8.0.0.0	Command introduced.

  5GHz (ArubaOS 8.9.0.0 or later versions)
  6GHz (ArubaOS 8.9.0.0 or later versions)
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

Show AP radios registered to this controller.

Parameter	Description
ap-group	Allows you to filter radio information by AP group.
ap-name <ap-name>	Allows you to filter radio information by AP name.
dot11a (For versions prior to ArubaOS 8.9.0.0)	Allows you to filter 802.11a radio information.
dot11g (For versions prior to ArubaOS 8.9.0.0)	Allows you to filter 802.11g radio information.
2.4GHz (ArubaOS 8.9.0.0 or later versions)	Allows you to filter 2.4 GHz radio information.
5GHz (ArubaOS 8.9.0.0 or later versions)	Allows you to filter 5 GHz radio information.
6GHz (ArubaOS 8.9.0.0 or later versions)	Allows you to filter 6 GHz radio information.
ip-addr <ip-addr>	Allows you to filter radio information by IP address.
ip6-addr <ip6-addr>	Allows you to filter radio information by IPv6 address.

Example

The output of the command in the following example displays statistics for the AP's radio, as well as statistics for transmitted and received frames.

In the actual CLI, it will appear in a single, long table.

```
(host) [mynode] #show ap radio-summary
APs Radios information
-----
Name                Group                AP Type  IP Address          Band  Mode

NF: Noise Floor(dBm); U: Utilization(%); I: Interference(%)
TD: Time used by data frames (%); TM: time used by mgnt frames(%); time used
by ctrl frames (%)
Total Radios:6
```

The output of this command includes the following information:

Parameter	Description
Name	Name of the AP.
Group	Group to which AP radio is assigned.
AP Type	AP model.
IP Address	Radio IP address.
Band	Band on which radio is operating on (2.4 GHz or 5 GHz) (For versions prior to ArubaOS 8.9.0.0)/2.4 GHz, 5 GHz, or 6 GHz (ArubaOS 8.9.0.0 or later versions).
Mode	Mode on which radio is operating; AP: AP Mode; AM: Air Monitor Mode, Spectrum: Spectrum Monitor Mode. Optionally, you can also specify the channel number.
EIRP/Max EIRP	Current EIRP output and maximum EIRP allowed for this radio (dBm).
NF/U/I	Noise Floor (dBm) / Utilization (%) / Interference (%).

Parameter	Description
TD	Time used by data frames (%).
TM	Time used by mgmt frames(%).
TC	Time used by ctrl frames (%).

Command History

Version	Modification
ArubaOS 8.9.0.0	<p>The following changes were made:</p> <ul style="list-style-type: none"> ■ Replaced <code>dot11a</code> and <code>dot11g</code> with <code>5GHz</code> and <code>2.4GHz</code> parameters respectively (ArubaOS 8.9.0.0 or later versions).. ■ Introduced <code>6GHz</code> parameter for Wi-Fi 6E APs (ArubaOS 8.9.0.0 or later versions). ■ Introduced 6GHz value for <code>Band</code> output parameter (ArubaOS 8.9.0.0 or later versions).
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap regulatory

show ap regulatory

Description

Shows the currently active Regulatory Cert.

Example

The example below shows the version of Regulatory Cert currently active on the controller.

```
(host) [mynode] #show ap regulatory
Regulatory Version :1.0_43859
```

Related Commands

Command	Description
ap regulatory-domain-profile	This command configures an AP regulatory domain profile.

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap regulatory-domain-profile

show ap regulatory-domain-profile [<profile-name>]

Description

Show the list of regulatory domain profiles or the settings in an individual regulatory domain profile. Issue this command without the <profile> parameter to display the entire regulatory domain profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Show data for a specific regulatory domain profile.

Examples

The following example shows that the controller has three regulatory domain profiles. The **References** column lists the number of other profiles with references to the regulatory domain profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) [mynode] # show ap regulatory-domain-profile
Regulatory Domain profile List
-----
Name                               References  Profile Status
----                               -
corp-channel-profile                8
default                             10
channel-test                          1.
```

The following example displays the configuration settings for the profile **corp-channel-profile**. The output of this command shows the profile's country code and the valid channel and channel pairs for that profile (For versions prior to ArubaOS 8.9.0.0).

```
host) [mynode] #show ap regulatory-domain-profile corp-channel-profile
Regulatory Domain profile "corp-channel-profile"
-----
Parameter                           Value
-----
Country Code                          US

```

The output of this command includes the following information:

Column	Description
Country Code	Code that represents the country in which the APs will operate. The country code determines the 802.11 wireless transmission spectrum.

Column	Description
<p>UTB Filter Blocking Selection (For ArubaOS 8.9.0.0 or later versions)</p>	<p>This parameter displays the band on which the UTB limitation is applied in the regulatory-domainprofile. The utb filter supports channel band on both 5 GHz and 6 GHz. This parameter displays one of the following values:</p> <ul style="list-style-type: none"> ■ 5GHz—5 GHz for upper band blocking. ■ 6GHz—6 GHz for lower band blocking.
<p>OOB 6GHz scanning for AP-615</p>	<p>If enabled, OOB scanning on 6 GHz band is allowed. If disabled, OOB scanning on 6 GHz band is blocked. This switch is valid only for AP-615 access points in the 5GHz-and-2.4GHz operation mode. Disable the switch to enable the use of UNII-4 band. Default: Enabled.</p>

Column	Description
Valid 802.11g channel	Selected 802.11b/g channel available for use by an AP using the specified regulatory domain profile. These channels are limited to those valid for the profile's country code.
Valid 802.11a channel	Selected 802.11a channel available for use by an AP using the specified regulatory domain profile. These channels are limited to those valid for the country code.
Valid 802.11g 40MHz channel pair	Selected 802.11b/g 40 MHz channel pair available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.
Valid 802.11a 40MHz channel pair	Selected 802.11a 40 MHz channel pair available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.

Column	Description
Valid 802.11a 80MHz channel group	Selected 802.11a 80 MHz channel group available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.
Valid 6GHz channel (For ArubaOS 8.9.0.0 or later versions)	Selected 6 GHz channel available for use by an AP using the specified regulatory domain profile. These channels are limited to those valid for the profile's country code.
Valid 6GHz 40MHz channel pair (For ArubaOS 8.9.0.0 or later versions)	Selected 6 GHz 40 MHz channel pair available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.
Valid 6GHz 80MHz channel group (For ArubaOS 8.9.0.0 or later versions)	Selected 6 GHz 80 MHz channel group available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.

Column	Description
Valid 6GHz 160MHz channel group (For ArubaOS 8.9.0.0 or later versions)	Selected 6 GHz 160 MHz channel group available for use by an AP using the specified domain profile. These channels are limited to those valid for the profile's country code.

Related Commands

Command	Description
ap regulatory-domain-profile	This command configures an AP regulatory domain profile.

Command History

Version	Modification
ArubaOS 8.11.0.0	The command output was modified to display OOB 6GHz scanning for AP-615 settings.
ArubaOS 8.9.0.0	The command output was modified to display the following new parameters (For ArubaOS 8.9.0.0 or later versions): <ul style="list-style-type: none"> ■ UTB Filter Blocking Selection ■ Valid 6GHz channel ■ Valid 6GHz 40MHz channel pair ■ Valid 6GHz 80MHz channel group ■ Valid 6GHz 160MHz channel group
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap remote auth-trace-buf

```
show ap remote auth-trace-buf {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}
```

Description

This command shows authentication trace buffer on an AP.

Parameter	Description
ap-name <ap-name>	Shows authentication trace buffer on an AP for specified AP name.
bssid <bssid>	Shows authentication trace buffer on an AP for specified BSSID.
ip-addr <ip-addr>	Shows authentication trace buffer on an AP for specified IP address.
ip6-addr <ip6-addr>	Shows authentication trace buffer on an AP for specified IPv6 address.

Example

The following example shows authentication trace buffer on an AP named ap-205:

```
(host) [mynode] #show ap remote auth-trace-buf ap-name ap-205  
  
Auth Trace Buffer  
-----
```

Related Commands

Command	Description
aaa auth-trace	This command sets parameters for debug tracing in AUTH (light weight tracing).

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap remote blacklist-clients/show ap remote denylist -clients

```
show ap remote blacklist-clients/show ap remote denylist -clients [ap-name <ap-name>] [bssid <bssid>] [ip-addr <ip-addr>]
```

Description

This command shows all clients blacklisted/denylisted.

Parameter	Description
ap-name <ap-name>	Shows all blacklisted/denylisted clients filtered by AP name.
bssid <bssid>	Shows all blacklisted/denylisted clients filtered by BSSID.
ip-addr <ip-addr>	Shows all blacklisted/denylisted clients filtered by IP address.

Example

The following example shows all blacklisted/denylisted clients:

```
(host) [mynode] #show ap remote blacklist-clients ap-name ap-205

Blacklisted Clients
-----
STA  reason  block-time(sec)  remaining time(sec)  Flags
---  -
Flags: R: reject associations
```

Starting from ArubaOS 8.9.0.0, the output of the command is displayed as follows:

```
(host) [mynode] #show ap remote denylist-clients ap-name ap-205

Denylisted Clients
-----
STA  reason  block-time(sec)  remaining time(sec)  Flags
---  -
Flags: R: reject associations
```

Related Commands

Command	Description
stm add-blacklist-client /add-denylist-client	Manually add clients from a blacklist/denylist.
stm remove-blacklist-client/remove-denylist-client <macaddr>	Manually remove clients from a blacklist/denylist.

show ap remote blacklist-clients-driver / show ap remote denylist-clients-driver  
[ap-name <ap-name>] [bssid <bssid>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>]
```

Description

This command shows all clients blacklisted/denylisted in the driver.

Parameter	Description
ap-name <ap-name>	Shows all clients blacklisted/denylisted in the driver filtered by AP name.
bssid <bssid>	Shows all clients blacklisted/denylisted in the driver filtered by BSSID.
ip-addr <ip-addr>	Shows all clients blacklisted/denylisted in the driver filtered by IP address.
ip6-addr <ip6-addr>	Shows all clients blacklisted/denylisted in the driver filtered by IPv6 address.

Example

The following example shows all clients blacklisted/denylisted in the driver:

```
(host) [mynode] #show ap remote blacklist-clients-driver ap-name ap-205  
  
Clients Blacklisted in Driver  
-----  
STA  
---
```

Starting from ArubaOS 8.9.0.0, the output of the command is displayed as follows:

```
(host) [mynode] # show ap remote denylist ap-name ap-205  
  
Clients Denylisted in Driver  
-----  
STA  
---
```

Related Commands

Command	Description
stm	This command is used to manually disconnect a client from an AP or control the denylisting of clients.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show ap remote bss-table

```
show ap remote bss-table [ap-name <ap-name>] [bssid <bssid>] [ip-addr <ip-addr>]  
[ip6-addr <ip6-addr>]
```

Description

This command shows BSSIDs of all APs registered on the managed device. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows BSSIDs of all APs registered on the managed device filtered by AP name.
bssid <bssid>	Shows BSSIDs of all APs registered on the managed device filtered by BSSID.
ip-addr <ip-addr>	Shows BSSIDs of all APs registered on the managed device filtered by IP address.
ip6-addr <ip6-addr>	Shows BSSIDs of all APs registered on the managed device filtered by IPv6 address.

Example

The following example shows the BSSID of an AP registered on the managed device (For versions prior to ArubaOS 8.9.0.0).

```
(host) [mynode] #show ap remote bss-table ap-name ap-205

```

The output of this command includes the following information:

Column	Description
bss	The AP Basic Service Set Identifier (BSSID). This is usually the MAC address of the AP
ess	The AP Extended Service Set Identifier (ESSID).
port	The slot and port used by the controller, in the format <slot>/<module>/<port>.
ip	IP address of an AP.

Column	Description
phy (For versions prior to ArubaOS 8.9.0.0)	The radio's PHY type. Possible values are 802.11a, 802.11a-HT-40, 802.11b or 802.11g, 802.11b or 802.11g-HT-20.
band/ht-mode/bandwidth (ArubaOS 8.9.0.0 or later versions)	The AP radio type displayed as radio band/throughput type/channel bandwidth. Possible values for each type are as follows: <ul style="list-style-type: none"> band—2.4GHz, 5GHz, or 6GHz ht-mode—HT, VHT, or HE bandwidth—20MHz, 40MHz, 80MHz, 80+80MHz, or 160MHz
ch/EIRP/max-EIRP	Radio channel used by the AP/current effective Isotropic Radiated Power (EIRP) /maximum EIRP.
type	Shows whether the AP is working as an access point (AP) or air monitor (AM).
cur-cl	Current number of clients on the AP.
ap name	Name of the AP.
in-t (s)	Number of seconds that an AP has been inactive.
tot-t	An AP's total active time, in seconds.
flags	The type of flags available for the AP.

Command History

Release	Modification
ArubaOS 8.9.0.0	The command output was modified to include the following: <ul style="list-style-type: none"> Replaced <code>phy</code> parameter with <code>band/ht-mode/bandwidth</code>. Added x and 3 flags.
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show ap remote client status

```
show ap remote client status [ap-name <ap-name>] [bssid <bssid>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>] <client-mac>
```

Description

This command shows association state of clients. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows association state of clients filtered by AP name.
bssid <bssid>	Shows association state of clients filtered by BSSID.
ip-addr <ip-addr>	Shows association state of clients filtered by IP address.
ip6-addr <ip6-addr>	Shows association state of clients filtered by IPv6 address.
<client-mac>	MAC address of client.

Example

The following example shows association state of clients:

```
(host) [mynode] #show ap remote client status ap-name ap-205  
00:1a:1e:aa:bb:cc
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The ip6-addr parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show ap remote counters

```
show ap remote counters {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

Description

Show the numbers of message counters for Remote APs.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific Basic Service Set Identifier (BSSID) on an AP. You must specify an AP's BSSID, which is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address.

Example

Use this command to determine the number of message counters recorded for each counter type seen by the remote AP. The output of the command in the example below shows counters for Remote AP State and VoIP CAC State Announcements:

```
(host) [mynode] #show ap remote counters ap-name a122

Counters
-----
Name                               Value
----                               -
Remote AP State                     62851
VoIP CAC State Announcement         13605
```

The output of this command includes the following information:

Column	Description
Name	Name of the counter type.
Value	Number of counters recorded since the AP was last reset.

show ap remote-debug-pkt

```
show ap remote-debug-pkt [logs|status] {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command displays the packet debugging details of an AP.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
logs {ap-name <ap-name> ip-addr <ip-addr> ip6-addr <ip6-addr>}	Shows packet debugging logs.
status {ap-name <ap-name> ip-addr <ip-addr> ip6-addr <ip6-addr>}	Shows packet debugging status.

Example

The following command displays the packet debugging status of an AP.

```
(host) [mynode] #show ap remote-debug-pkt status ip-addr 10.82.113.45
Debug pkt status at AP655
-----
Dump is not started, run 'ap remote-debug-pkt dump start' to enable
Mirror is not started, run 'ap remote-debug-pkt mirror' to mirror them
```

```
Run 'ap remote-debug-pkt type' to config debug types
```

Command History

Version	Modification
ArubaOS 8.11.0.0	Command introduced.

Command Information

show ap remote debug anul-sta-entries

```
show ap remote debug anul-sta-entries {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

Displays a list of VAPs and stations stored in the AP's datapath. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Show LACP information for an AP with a specific name.
radio <radio>	Shows the radio ID. Valid values are 0 and 1.
ip-addr <ip-addr>	Show LACP information for an AP with a specific IPv4 address.
ip6-addr <ip6-addr>	Show LACP information for an AP with a specific IPv6 address.

Example

Using the following example, for 320 Series, check the LAG columns to see if any packets are dropped.

```
(host) [mynode] #show ap remote debug anul-sta-entries ap-name ap325
ANUL BSS Table for Radio 0
-----
bssid                num_stas  data ready drops
-----
AC:A3:1E:53:5C:F0    2          0
ANUL STA State
-----
mac                  bssid                aid  data ready  bss  Drops  LAG  LAG
drops
---                  ---                  ---  -----  ---  -----  ---  ----
-----
3C:A9:F4:24:B2:54    AC:A3:1E:53:5C:F0    2    Yes         B    0      Yes  0
78:31:C1:BC:D6:12    AC:A3:1E:53:5C:F0    1    Yes         B    0      Yes  0
```

The following parameters appear in the output of the `show ap remote debug anul-sta-entries` command and are useful for debugging purposes.

Parameter	Description
bssid	The BSSID of the VAP.
num_stas	Indicates the number of stations associated to a VAP.
data ready drops	Indicates the total packets received and dropped before clients were ready to receive data packets.
ANUL STA State	
mac	The MAC address of a client.
bssid	The BSSID of the VAP that the client is associated to.
aid	The association ID of the station.
data ready	Indicates if the client has completed authentication.
bss	Indicates if a client is associated to a BSS or not. The B flag indicates that the client is associated to a BSS. The F flag indicates that the entry is free and not attached to any BSS.
Drops	Indicates the number of data packets received and dropped before data ready is set to yes.
LAG	Indicates if link aggregation is used to achieve HT by transmitting the packets on both Ethernet ports, for a given station. This field is displayed only in 320 Series access points.
LAG drops	Indicates the number of packets dropped by the AP due to packets reordered in the network by link aggregation. This field is displayed only in 320 Series access points.

Command History

Version	Modification
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on managed devices.

show ap remote debug association

```
show ap remote debug association
  {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>} [uac
  <uac>]
```

Description

This command shows the association table of the AP to identify the clients associated to each AP. Use this command to verify if a remote user is connected to an AP and to validate the AP to which is connected. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows client associations for the specified AP name.
bssid <bssid>	Show client associations for an specific BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Shows client associations for the specified IP address.
ip6-addr <ip6-addr>	Shows client associations for the specified IPv6 address.

Example

The output of this command displays information about the remote clients associated with an AP with the IP address 192.0.2.32:

```
(host) [mynode] #show ap remote debug association ip-addr 192.0.2.32

Flags: W: WMM client, A: Active, R: RRM client

PHY Details: HT: High throughput; 20: 20MHz; 40: 40MHz
             <n>ss: <n> spatial streams

Association Table
-----
Name  bssid                mac                auth  assoc  aid  l-int  essid
----  -
AP71  00:0a:23:c1:d4:11    00:16:6d:08:1s:f1  y     y     1   10     t-lab

vlan-id  tunnel-id  phy  assoc. time  num assoc  Flags
-----  -
111      0x108e    a

Num Clients:1
```

The output of this command includes the following information:

Column	Description
Name	Name of an AP.
bssid	The AP BSSID.
mac	MAC address of the client.
auth	This column displays a y if the AP has been configured for 802.11 authorization frame types. Otherwise, it displays an n .
assoc	This column displays a y if the AP has been configured for 802.11 association frame types. Otherwise, it displays an n .
aid	802.11 association ID. A client receives a unique 802.11 association ID when it associates to an AP.
l-int	Number of beacons in the 802.11 listen interval. There are ten beacons sent per second, so a ten-beacon listen interval indicates a listen interval time of 1 second.
essid	Name that uniquely identifies the AP's ESSID.
vlan-id	Identification number of the AP's VLAN.
tunnel-id	Identification number of the AP's tunnel.
phy	The RF band in which the AP operates: <ul style="list-style-type: none"> ■ a = 5 GHz ■ b, g = 2.4 GHz From ArubaOS 8.9.0.0 or later versions, the following values are displayed: <ul style="list-style-type: none"> ■ 2.4GHz ■ 5GHz ■ 6GHz (For Wi-Fi 6E APs)
assoc. time	Amount of time the client has associated with the AP, in the format hours:minutes:seconds.
num assoc	Number of clients associated with the AP.
flags	This column displays any flags for this AP. The list of flag abbreviations is included in the output of the <code>show ap association</code> command.

Command History:

Release	Modification
ArubaOS 8.9.0.0	The command output was modified to display the following values for <code>phy</code> parameter (For ArubaOS 8.9.0.0 or later versions): <ul style="list-style-type: none"> ■ 2.4GHz ■ 5GHz ■ 6GHz (For Wi-Fi 6E APs)
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show ap remote debug association-failure

```
show ap remote debug association-failure
  {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}[client-
  mac <client-mac>|ssid <ssid>]
```

Description

This command shows the association failure information.

Parameter	Description
ap-name <ap-name>	Shows AP association failure for the specified AP name. You may include the client-mac or ssid to filter the output.
bssid <bssid>	Shows AP associations for the specified BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Shows AP associations for the specified IP address. You may include the client-mac or ssid to filter the output.
ip6-addr <ip6-addr>	Shows AP associations for the specified IPv6 address. You may include the client-mac or ssid to filter the output.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The output of this command displays information about the association failure for an AP named **ap-205**:

```
(host) [mynode] #show ap remote debug association-failure ap-name ap-205

Association Failure Table
-----
MAC Address  AP Name  BSSID  ESSID  State  Radio  Idle Time  Reason
-----
Num Association Failures:0
```

Command History:

Release	Modification
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Configuration mode on managed devices.

show ap remote debug association-failure

```
show ap remote debug association-failure [{ap-name <ap-name>}|{bssid <bssid>}|{essid <essid>}]
```

Description

Display association failure information that can be used to troubleshoot problems on an AP. Use this command to determine whether the client is associated and identify the last AP to which it was connected.

Parameter	Description
ap-name <ap-name>	Filter the Association Failure Table by AP name.
bssid <bssid>	Filter the Association Failure Table by BSSID. The BSSID is usually the AP's MAC address.
essid <essid>	Filter the Association Failure Table by ESSID of an AP.

Example

The output of the command `show ap remote debug association-failure` displays the Association Failure Table. If the **Idle time** column in the output of this command is a low value, the **reason** column will describe why the association failed.

```
(host) [mynode] #show ap remote debug association-failure ap-name AP-65-
port3
Association Failure Table
-----
MAC Address      AP Name  BSSID                ESSID  State  Radio  Idle
Time    Reason
-----
---
00:16:6f:09:54:3e AL29      00:1a:1e:11:6f:00  guest                802.11g
20h:39m:33s Denied; AP Going Down
00:16:6f:09:54:3e AL33      00:1a:1e:11:6e:60  guest  auth    802.11g
20h:39m:33s Unspecified Failure
00:16:6f:09:54:3e AL40      00:1a:1e:8d:5b:20  guest                802.11g
20h:39m:33s Denied; Ageout
Num Association Failures:3
```

The output of this command includes the following parameters:

Column	Description
MAC address	MAC address of the client that failed to associate with an AP.
AP Name	Name of an AP to which the client attempted to associate.
BSSID	BSSID of an AP.
ESSID	ESSID of an AP.
State	This data column shows if the client is currently authorized or both authorized and ESSID associated with an AP.
Radio	The AP radio type.
Idle Time	Amount of time that the client has been idle, in the format <i>hours:minutes:seconds</i> .
Reason	A brief description of the reason why the client failed to associate.

Command History

Command	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode

show ap remote debug bss-config

```
show ap remote debug bss-config {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

Shows the configuration for each BSSID of an AP. This information can be used to troubleshoot problems on an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Filter the AP Config Table by AP name.
bssid <bssid>	Shows AP associations for the specified BSSID. A BSSID is usually the MAC address of an AP.
ip-addr <ip-addr>	Filter the AP Config Table by IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Filter the AP Config Table by IPv6 address by entering an IPv6 address in dotted-decimal format.

Example

The following example shows the AP configuration table for a specific BSSID (For versions prior to ArubaOS 8.9.0.0):

```
(host) [mynode] #show ap remote debug bss-config ap-name ap93-3
Aruba AP Config Table
bssid      ess      vlan ip      phy  type  fw-mode

```

The output of this command includes the following information:

Column	Description
bss	BSS identifier, which is usually the AP's MAC address.
ess	ESS identifier; a user-defined name for a wireless network.
vlan	The BSSID VLAN number.
IP	The AP IP address.
phy	One of the following 802.11 types

Column	Description
(For versions prior to ArubaOS 8.9.0.0)	<ul style="list-style-type: none"> ■ a ■ a-HT ■ g ■ g-HT
band/ht-mode/bandwidth (ArubaOS 8.9.0.0 or later versions)	<p>The AP radio type displayed by radio band/throughput type/channel bandwidth. Possible values for each type are as follows:</p> <ul style="list-style-type: none"> ■ band—2.4GHz, 5GHz, or 6GHz ■ ht-mode—HT, VHT, or HE ■ bandwidth—20MHz, 40MHz, 80MHz, 80+80MHz, or 160MHz
type	This column shows if the BSSID is for an AP or an AM.
fw-mode	<p>The configured forward mode for the AP's virtual AP profile.</p> <ul style="list-style-type: none"> ■ bridge: Bridge locally ■ split-tunnel: Tunnel to controller or NAT locally ■ tunnel: Tunnel to controller
max-cl	The maximum number of clients allowed for this BSSID.
preamble	Shows if short preambles are enabled for 802.11b or 802.11g radios. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using a short preamble.
MTU	MTU size, in bytes. This value describes the greatest amount of data that can be transferred in one physical frame.
status	Shows if this BSSID is enabled or disabled.
wmm	Shows if the BSSID has enabled or disabled WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF) WMM provides prioritization of specific traffic relative to other traffic in the network.

Command History

Release	Modification
ArubaOS 8.9.0.0	The command output was modified to include the following: <ul style="list-style-type: none"> Replaced <code>phy</code> parameter with <code>band/ht-mode/bandwidth</code>. Added x and 3 flags.
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show ap remote debug bucketmap datapath

```
show ap remote debug bucketmap datapath {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} essid <essid>
```

Description

This command shows bucket maps in AP datapath.

Parameter	Description
ap-name <ap-name> essid <essid>	Shows bucket maps filtered by specified AP name and ESSID.
ip-addr <ip-addr> essid <essid>	Shows bucket maps filtered by specified IP address of an AP and ESSID.
ip6-addr <ip6-addr> essid <essid>	Shows bucket maps filtered by specified IPv6 address of an AP and ESSID.

Example

Access the CLI and use the following command to show bucket maps in AP datapath filtered by the AP **test** and ESSID **default**:

```
(host) [mynode] #show ap remote debug bucketmap datapath ap-name test essid default

show ap remote debug bucketmap sapd

```
show ap remote debug bucketmap sapd {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} essid <essid>
```

Description

This command shows bucket map received from cluster by SAPD process.

Parameter	Description
ap-name <ap-name> essid <essid>	Shows bucket maps received from cluster by SAPD filtered by specified AP name and ESSID.
ip-addr <ip-addr> essid <essid>	Shows bucket maps received from cluster by SAPD filtered by specified IP address of an AP and ESSID.
ip6-addr <ip6-addr> essid <essid>	Shows bucket maps received from cluster by SAPD filtered by specified IPv6 address of an AP and ESSID.

Example

Access the CLI and use the following command to show bucket map received from cluster by SAPD process filtered by AP **test** and ESSID **default**:

```
(host) [mynode] #show ap remote debug bucketmap sapd ap-name test essid default

show ap remote debug bucketmap stm

```
show ap remote debug bucketmap stm {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [essid <essid>]
```

Description

This command shows bucket map received from cluster by AP STM. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name> essid <essid>	Shows bucket map received from cluster by AP STM filtered by specified AP name and ESSID.
ip-addr <ip-addr> essid <essid>	Shows bucket map received from cluster by AP STM filtered by specified IP address of an AP and ESSID.
ip6-addr <ip6-addr> essid <essid>	Shows bucket map received from cluster by AP STM filtered by specified IPv6 address of an AP and ESSID.

Example

Access the CLI and use the following command to show bucket map received from cluster by AP STM filtered by AP **test** and ESSID **default**:

```
(host) [mynode] #show ap remote debug bucketmap stm ap-name test essid default

show ap remote debug bucketmap-counters

```
show ap remote debug bucketmap-counters {ap-name <ap-name> | ip-addr <ip-addr>
| ip6-addr <ip6-addr>}
```

Description

This command shows bucket map counters. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows bucket map counters filtered by specified AP name.
ip-addr <ip-addr>	Shows bucket map counters filtered by specified IP address of an AP.

Example

Access the CLI and use the following command to bucket map counters filtered by the AP name test:

```
(host) [mynode] #show ap remote debug bucketmap-counters ap-name test

Bucketmap Counters
-----
Name                                     Value
----                                     -
Bucketmap Updates, trunc errors         0 0
AP Bucketmap Updates Without Initialization 0
AP Bucketmap Lookup Failed              0
AP Bucketmap Allocation Failed          0
On AP STA Lookup UAC Failed             0
UAC Up/Down Events                      4 0
UAC Changed in Bmaps                   0
Deauth dropped from non-UAC             0
Deauths : New Bmap, Node Down not L2, node down no UAC 0, 0, 0
```

show ap remote debug client-mgmt-counters

```
show ap remote debug client-mgmt-counters {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

Shows the number of each type of message from the clients of an AP. This information can be used to troubleshoot problems on an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
show ap remote debug client-mgmt-counters	Use this command to display message counters.
ap-name <ap-name>	To show message counters by AP name.
bssid <bssid>	To show message counters by MAC address of AP.
ip-addr <ip-addr>	To show message counters by IP address of AP.
ip6-addr <ip6-addr>	To show message counters by IPv6 address of AP.

Example

The output of this command shows client management counters for the specified AP:

```
(host)[mynode] #show ap remote debug client-mgmt-counters ap-name ap120-3

DPH TX txnid                          0
DPH TX total                          23

```

The output of this command includes the following information:

Parameter	Description
Validate Client	Number of times a client was validated.
AP Stats Update Message	Number of times an AP updated its statistics with the managed device.

Parameter	Description
ARM Update	Number of times an AP has changed its ARM settings.
STA On Call Message	Number of counters indicating that a station has an active phone call.
STA SIP authenticate Message	Number of messages indicating that a telephone has completed SIP registration and authentication.
STA Deauthenticate	Number of times a station sent a message to an AP to deauthenticate a client.
assoc-req	Number of 802.11 association request management frames from the controller.
assoc-resp	Number of 802.11 association responses to the controller.
reassoc-req	Number of 802.11 reassociation requests to the controller.
reassoc-resp	Number of 802.11 reassociation responses from the controller.
disassoc	Number of 802.11 disassociation messages to the controller.
deauth	Number of 802.11 deauthorization messages from the controller.

Command History

Release	Modification
ArubaOS 8.7.0.0	The following ASAP AP APP stats messages and record counters were introduced: <ul style="list-style-type: none"> ■ total ■ null sap ■ empty ■ error ■ queued ■ sent
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug flash-config

```
show ap remote debug flash-config {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip6-addr>} acls | vap <vap> | vaps
```

Description

Show the remote AP configuration stored in flash memory.

Parameter	Description
ap-name <ap-name>	Shows debugging data for an AP with a specific name.
bssid <bssid>	Shows data for a specific BSSID on an AP. The BSSID is usually the MAC address of the AP.
ip-addr <ip-addr>	Shows data for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Shows data for an AP with a specific IP6 address by entering its IP6 address in dotted-decimal format.
acls	Displays ACLs of offline virtual APs.
vap <vap>	Displays the configuration of a specific offline virtual AP by entering the name of a virtual AP.
vaps	Displays the current number of offline virtual APs.

Example

The output of this command can be used to debug problems with a remote AP. The command below shows statistics for an AP with the IP address 192.0.2.64.

```
(host) [mynode] #show ap remote debug flash-config ip-addr 192.0.2.64
acls
Offline ACLs
-----
Item                Value
----                -
Native VLAN        1
DHCP VLAN          N/A
DHCP ADDR          192.168.11.1
DHCP POOL NETMASK  255.255.255.0
DHCP POOL START    192.168.11.2
DHCP POOL END      192.168.11.254
DHCP DNS SERVER    0.0.0.0
DHCP ROUTER        192.168.11.1
DHCP DNS DOMAIN    mycompany
```

```

DHCP LEASE          0
Session ACL        N/A
Session ACL Name   N/A
Session ACL Count  N/A
Session Aces       N/A
ACL 1              1
ACL 1 Name         logon
ACL 1 Count        21
Aces 1             16 1 4294
...

```

The output of this command includes the following information:

Parameter	Description
Native VLAN	VLAN ID of the native VLAN.
DHCP VLAN	VLAN ID of Remote AP DHCP server used when the controller is unreachable.
DHCP ADDR	IP Address used as DHCP Server Identifier.
DHCP POOL NETMASK	Netmask of the DHCP server pool.
DHCP POOL START	IP Address used as the start of a range of addresses for a DHCP pool.
DHCP POOL END	IP Address used as the end of a range of addresses for a DHCP pool.
DHCP DNS SERVER	IP Address for the DHCP DNS server.
DHCP ROUTER	IP Address for the DHCP default router.
DHCP DNS DOMAIN	Domain name for the DHCP DNS server.
DHCP LEASE	Length of DHCP DNS leases in days. If this parameter displays a zero (0), the DHCP lease has no defined end.
Session ACL	Name of the ACL applied to the user session.
Session ACL name	Name of the ACL applied to the user session.
Session ACL count	Number of rules in the applied to the user session.
Session Aces	A list of the individual rules in the session ACL.
ACL 1	This parameter shows the position of an individual ACL.
ACL1 Name	Name of the ACL in the first position.
ACL1 Count	Number of rules in the specified ACL.

Parameter	Description
ACL1 Aces	A list of the individual rules in the specified ACL.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug-mcast-forwarder

```
show ap remote debug-mcast-forwarder {ap-name <ap-name> | ip-addr <ip-addr>
```

Description

This command displays the Mcast forwarder status for the selected AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows debugging information for a specific AP.
ip-addr <ip-addr>	Shows debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.

Example

Use this command to display the mcast forwarder status for an AP:

```
(host) [mynode] #show ap remote debug-mcast-forwarder ip-addr
191.191.191.323
Status (0): OFF, VLANs: 1
Mcast Aggregation Forwarder election status:
-----
VLAN  Forwarder  TX  RX
----  -
1     itself     0   0
Forwarder:mcast packets forwarder on the VLAN
TX:output announcement number for forwarder election on the VLAN
RX:input announcement number for forwarder election on the VLAN
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug mgmt-frames

```
show ap remote debug mgmt-frames {ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>} [client-mac <client-mac>] [count <count>]
```

Description

This command shows traced 802.11 management frames for a remote AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Show debugging information for a specific AP.
ip-addr <ip-addr>	Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show debugging information for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.
client-mac <client-mac>	Show the AP associations for a specific MAC address by entering the MAC address of the client.
count <count>	Limit the amount of information displayed by specifying the number of frames to appear in the output of this command. Range: 1-128

Example

Use this command to debug 802.1 authentication on a remote AP. The example below shows that a client successfully associated with the remote AP, then was later deauthenticated.

```
(host) [mynode] #show ap remote debug mgmt-frames ap-name AP32
```

The output of this command includes the following information:

Parameter	Description
Timestamp	The time the management frame was sent.
stype	One of the following 802.11 frame types: auth: Authorization frame

Parameter	Description
	death: Deauthorization frame assoc-resp: Association response assoc-req: Association request
SA	Source MAC address.
DA	Destination MAC address.
BSS	BSSID of the AP.
signal	Signal strength as a signal to noise ratio. For example, a value of 30 would indicate that the power of the received signal is 30 dBm above the signal noise threshold.
Misc	Additional information describing the client's action. In the case of deauthentication, a reason associated with the event will be displayed in this column.

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug neighbor-cache

```
show ap remote debug neighbor-cache {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command displays the per-ESSID neighbor cache of AP.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the wired port bounce configuration for the specified AP name.
ip-addr <ip-addr>	Shows the wired port bounce configuration for the specified IPv4 address.
ip6-addr <ip6-addr>	Shows the wired port bounce configuration for the specified IPv6 address.

Example

The following example displays the cached neighbors of a Wi-Fi 6E AP.

```
(host) [mynode] #show ap remote debug neighbor-cache ap-name hhm-635

Cached neighbors for 8@hhm-635-psk
-----
BSSID           Band  Channel  Operating Class  Signal  opmode  Flags
-----
cc:88:c7:41:64:60 6GHz  37       131              150     6       hWU

Flags: h = 802.11h support; W = WMM support; U = WMM UAPSD
       k = 802.11k support; R = 802.11r support
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The command output was modified to include the Band parameter.
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug nodelist history

```
show ap remote debug nodelist history {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command shows the cluster node history for a remote AP. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Show debugging information for a specific AP.
ip-addr <ip-addr>	Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show debugging information for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap remote debug nodelist history ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug redun-state history

```
show ap remote debug redun-state history {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}
```

Description

This command shows the cluster node history for a remote AP. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Show debugging information for a specific AP.
ip-addr <ip-addr>	Show debugging information for an AP with a specific IP address by entering its IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show debugging information for an AP with a specific IPv6 address by entering its IPv6 address in dotted-decimal format.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap remote debug redun-state history ap-name ap-205
Redun Event History
-----
PID and Time          Error          Event          Information

```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug sapd

```
show ap remote debug sapd cluster-nodestate
  ap-name
  ip-addr
  ip6-addr
```

Description

This command displays the state of cluster node in the SAPD process.

Parameter	Description
ap-name	Shows state of cluster node for specified AP name.
ip-addr	Shows state of cluster node for specified IP address.
ip6-addr	Shows state of cluster node for specified IPv6 address.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms.	Base operating system.	Config mode in managed devices.

show ap remote debug stale_sta

```
show ap remote debug stale_sta {ap-name <ap-name> | bssid <bssid>| ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows information for debugging an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
show ap remote debug stale_sta	Shows stale station entries stored on the AP.
ap-name <ap-name>	Shows stale stations based on the AP name filter.
bssid <bssid>	Shows stale stations based on the AP MAC address filter.
ip-addr <ip-addr>	Shows stale stations based on the IP address filter of the AP.
ip6-addr <ip6-addr>	Shows stale stations based on the IPv6 address filter of the AP.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap remote debug stale_sta ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The ip6-addr parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug sta-msg-sta-down-entries

```
show ap remote debug sta-msg-sta-down-entries {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows STA message for STA Down list. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows STA message for STA Down list of the specified AP.
ip-addr <ip-addr>	Shows STA message for Down list of the specified IP address.
ip6-addr <ip6-addr>	Shows STA message for Down list of the specified IPv6 address.

Example

The execution of the following command displays the STA Down list:

```
(host) [mynode] #show ap remote debug sta-msg-sta-down-entries ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The ip6-addr parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show ap remote debug sta-msg-stats

```
show ap remote debug sta-msg-stats {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows statistics of messages between AP and AC relating to STA associations on the AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows statistics of messages between AP and AC relating to STA associations for specified AP name.
ip-addr <ip-addr>	Shows statistics of messages between AP and AC relating to STA associations for specified IP address.
ip6-addr <ip6-addr>	Shows statistics of messages between AP and AC relating to STA associations for specified IPv6 address.

Example

The following example shows an example for executing this command:

```
(host) [mynode] #show ap remote debug sta-msg-stats ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The ip6-addr parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug stm cluster-nodestate

```
show ap remote debug stm cluster-nodestate {ap-name <ap-name> | ip-addr <ip-addr>
| ip6-addr <ip6-addr>}
```

Description

This command shows the cluster node state in AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the cluster node state for specified AP name.
ip-addr <ip-addr>	Shows the cluster node state for specified IP address.
ip6-addr <ip6-addr>	Shows the cluster node state for specified IPv6 address.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap remote debug stm cluster-nodestate ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The ip6-addr parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show ap remote debug stm trace-files

```
show ap remote debug stm trace-files {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows STM trace files for an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the STM trace files for specified AP name.
ip-addr <ip-addr>	Shows the STM trace files for specified IP address.
ip6-addr <ip6-addr>	Shows the STM trace files for specified IPv6 address.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap remote debug stm trace-files ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show ap remote debug uac-list

```
show ap remote debug uac-list {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows user anchor controller (UAC) list in AP datapath. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the UAC list in AP datapath for the specified AP name.
ip-addr <ip-addr>	Shows the UAC list in AP datapath for the specified IP address.
ip6-addr <ip6-addr>	Shows the UAC list in AP datapath for the specified IPv6 address.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap remote debug uac-list ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show ap remote debug web-server-config

```
show ap remote debug web-server-config {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command displays the web server profile configurations on the AP.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the web server profile configuration for the specified AP name.
ip-addr <ip-addr>	Shows the web server profile configuration for the specified IPv4 address.
ip6-addr <ip6-addr>	Shows the web server profile configuration for the specified IPv6 address.

Example

The following example displays the web server profile fields configured on APs:

```
(host) [mynode] (config) #show ap remote debug web-server-config ip-addr 10.65.39.213

Web Server Configuration
-----
Cipher  SSL      Cert
-----  ---      ----
high    tlsv1.2  default
```

The output of this command includes the following parameters:

Parameter	Description
Cipher	The cipher suite strength displaying one of the following values: <ul style="list-style-type: none">■ high■ medium■ low high

Parameter	Description
SSL	The SSL/TLS protocol type displaying one of the following values: <ul style="list-style-type: none"> ■ tlsv1 ■ tlsv1.1 ■ tlsv1.2 tlsv1.2
Cert	The server certificate for captive portal.

Command History

Release	Modification
ArubaOS 8.8.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote debug wired-port-down-state

```
show ap remote debug wired-port-down-state {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command displays the wired port bounce configurations that are forwarded from the controller and AP's wired port status.

The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the wired port bounce configuration for the specified AP name.
ip-addr <ip-addr>	Shows the wired port bounce configuration for the specified IPv4 address.
ip6-addr <ip6-addr>	Shows the wired port bounce configuration for the specified IPv6 address.

Example

The following example displays AP's wired port status and the wired port bounce configurations that are forwarded from the controller:

```
(host) [mynode] #show ap remote debug wired-port-down-state ap-name ap-test

The configurations pushed from the controller
-----
The port bounce time by disable POE: 30
The port bounce time by shutdown ethernet link: 60
AP's wired port is in down time, the port status as below
-----
All wired ports' status
-----
Wired port Ethernet link status Whether Support PSE PSE status
-----
eth0          up                no
eth1          down              no
eth2          down              no
eth3          up                yes                enable
```

Command History

Release	Modification
ArubaOS 8.8.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote essid

```
show ap remote essid {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

Shows an ESSID summary for the Managed Device, including the numbers of APs and clients connected to a managed device. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the ESSID summary for the specified AP name.
bssid <bssid>	Shows the ESSID summary for the specified MAC address.
ip-addr <ip-addr>	Shows the ESSID summary for the specified IP address.
ip6-addr <ip6-addr>	Shows the ESSID summary for the specified IPv6 address.

Example

The following is an example for executing the `show ap remote essid` command:

```
(host) [mynode] #show ap remote essid ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap remote wmm-flow

```
show ap remote wmm-flow {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows the Wireless Multimedia (WMM) flows that are active on an AP connected to a Managed Device. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the WMM flows that are active for a specified AP name.
bssid <bssid>	Shows the WMM flows that are active for a specified MAC address.
ip-addr <ip-addr>	Shows the WMM flows that are active for a specified IP address.
ip6-addr <ip6-addr>	Shows the WMM flows that are active for a specified IPv6 address.

Example

The following is an example for executing the `show ap remote wmm-flow` command:

```
(host) #show ap remote wmm-flow ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>ip6-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap sapd-debug log

```
show ap sapd-debug log {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} | <page>
```

Description

This command displays the SAPD debug log for an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Shows the SAPD debug log for the specified AP name.
ip-addr <ip-addr>	Shows the SAPD debug log for the specified IP address.
ip6-addr <ip6-addr>	Shows the SAPD debug log for the specified IPv6 address.
<page>	Displays the specified page of the SAPD debug log information.

Example

The following is an example for executing the `show ap sapd-debug log` command:

```
(host) #show ap sapd-debug log ap-name ap-205
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show ap snmp

```
show ap snmp
  wlsxSwitchStationMgmtTable
  wlsxSwitchStationStatsTable
  wlsxWlanAPBssidTable
  wlsxWlanAPTable
  wlsxWlanESSIDTable
  wlsxWlanRadioTable
```

Description

This command displays the AP-related SNMP tables.

Parameter	Description
wlsxSwitchStationMgmtTable	Display user tree.
wlsxSwitchStationStatsTable	Display user statistics tree.
wlsxWlanAPBssidTable	Display BSSID SNMP tree.
wlsxWlanAPTable	Display SNMP tree.
wlsxWlanESSIDTable	Displays ESSID SNMP tree.
wlsxWlanRadioTable	Display radio table SNMP tree.

Example

The following command displays BSSID SNMP tree (For versions prior to ArubaOS 8.9.0.0).

```
(host)[mynode] #show ap snmp wlsxWlanAPBssidTable

SNMP - AP BSSID Table
-----
AP MAC           Radio  BSSID           Phy Type  Status  Channel
-----
00:24:6c:c3:d6:82  1     00:24:6c:bd:68:30  1         1       149
00:24:6c:c3:d6:82  2     00:24:6c:bd:68:20  2         1       11

Num BSSIDs:2
```

The following command displays BSSID SNMP tree for a Wi-Fi 6E AP(For ArubaOS 8.9.0.0 or later versions).

```
(host) [mynode] (config) #show ap snmp wlsxWlanAPBssidTable

SNMP - AP BSSID Table
-----
AP MAC           Radio  BSSID           Phy Type  Status  Channel
-----
84:d4:7e:c6:61:74  1     84:d4:7e:e6:17:50  1         1

Num BSSIDs:2
```

Related Commands

Command	Description
snmp-server	This command configures SNMP parameters.

Command History

Release	Modification
ArubaOS 8.9.0.0	The command output was modified to include 2.4GHz , 5GHz , and 6GHz values for Channel parameter.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms.	Base operating system.	Enable or Config mode on managed devices.

show ap spectrum ap-list

```
show ap spectrum ap-list {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [channel <channel> | essid <ssid> | freq-band {2.4ghz | 5ghz} | limit <limit> | or | page <page> | sort <sort> | start <start>]
```

Description

This command shows spectrum data seen by an access point that has been converted to a spectrum monitor.

The Spectrum Analysis feature provides visibility into RF coverage, allowing you to troubleshoot RF interference and identify 802.11 devices on the network. Use this command to display and sort APs seen by a specific spectrum monitor.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor for which you want to view spectrum information.
channel <channel>	View spectrum information for a specific radio channel.
ssid <ssid>	View spectrum information for a specific ESSID.
freq-band {2.4ghz 5ghz}	View information for a specific radio type, either 2.4 GHz or 5 GHz.
limit <limit>	Limit the displayed output to the specified number of entries
or	Use this parameter to display information that meets either of two criteria, such as a specified ESSID or channel.
page <page>	Enter a number from 10–100 (inclusive) to specify the number of entries that should appear in each page of the output for this command. For example, if the output of this command has 100 entries and you select a page value of 20, the output will appear in 5 pages each with 20 entries. If you selected a page value of 10, the output would appear in 10 pages with 10 entries.
sort <sort>	Sort the output by the specified data column.
start <start>	Start displaying the output at specific spectrum index value.

Example

The output of this example shows spectrum data seen by spectrum monitor ap123. The output in the example below has been divided into two tables to better fit this document. In the ArubaOS CLI, the output appears as a single, long table.

```
(host) [mynode]# show ap spectrum ap-list ap-name ap123

Spectrum AP Table
-----
bssid          essid          spectrum-id  chan  phy-type      signal

```

The output of this command includes the following information:

Column	Description
bssid	Basic Service Set Identifier for an AP. This is usually the MAC address of the AP.
ssid	Extended Service Set Identifier that names a wireless network.
spectrum-id	Identifier assigned to the device by the spectrum monitor.
chan	Radio channel used by the BSSID.
freq-band	Radio phy type. Possible types include: <ul style="list-style-type: none"> 2.4 GHz 5 GHz
signal (dBm)	Strength of the signal received by the device, in dBm.
avg-rssi	The average signal-to-noise ratio seen by the AP.
curr-rssi	Most recent signal-to-noise ratio seen by the AP.

Column	Description
ibss	Shows if ad hoc BSS is enabled or disabled. It will be enabled if the bssid has detected an ad hoc BSS (an ibss bit in an 802.11 frame).
add-time	Time when the AP was first detected by the spectrum monitor.
last-seen	Time when the AP was last seen by the spectrum monitor.

Related Commands

Command	Description
ap spectrum local-override	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.
rf dot11a-radio-profilemodespectrum-mode	Sets an 802.11a radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.

show ap spectrum channel-metrics

```
show ap spectrum channel-metrics {ap-name <ap-name>|ip-addr <ip-addr> | ip6-addr <ip6-addr>} [freq-band {2.4ghz | 5ghz | 6ghz}]
```

Description

This command shows channel quality, availability, and utilization metrics as seen by a spectrum monitor.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor.
freq-band {2.4ghz 5ghz} (For versions prior to ArubaOS 8.9.0.0)	View information for a specific radio type, either 2.4 GHz or 5 GHz.
freq-band {2.4ghz 5ghz 6ghz} (For ArubaOS 8.9.0.0 or later versions)	View information for a specific radio type, either 2.4 GHz, 5 GHz, or 6 GHz. NOTE: The 6ghz sub-parameter is applicable to Wi-Fi 6E APs only.

This chart displays channel utilization data, showing the percentage of each channel that is currently being used by Wi-Fi devices, and the percentage of each channel being used by non-Wi-Fi devices and 802.11 adjacent channel interference (ACI).

ACI refers to the interference on a channel created by a transmitter operating in an adjacent channel. A transmitter on a nonadjacent or partially overlapping channel may also cause interference, depending on the transmit power of the interfering transmitter and/or the distance between the devices. In general, ACI may be caused by a Wi-Fi transmitter or a non-Wi-Fi interferer. However, whenever the term ACI appears in Spectrum Analysis graphs, it refers to the ACI caused by Wi-Fi transmitters. The channel utilization option in the Channel Metrics Chart shows the percentage of the channel utilization due to both ACI and non-Wi-Fi interfering devices. Unlike the ACI shown in the [show ap spectrum interference-power](#) output, the ACI shown in this graph indicates the percentage of channel time that is occupied by ACI or unavailable for Wi-Fi communication due to ACI.

The Channel Metrics table can also show channel availability, the percentage of each channel that is available for use, or display the current relative quality of selected channels in the 2.4 GHz or 5 GHz radio bands. In the spectrum analysis feature, channel quality is a relative measure that indicates the ability of the channel to support reliable Wi-Fi communication. Channel quality, which is represented as a percentage in this chart, is a weighted metric derived from key

parameters that can affect the communication quality of a wireless channel, including noise, non-Wi-Fi (interferer) utilization and duty-cycles, and certain types of retries. Note that channel quality is not directly related to Wi-Fi channel utilization, as a higher quality channel may or may not be highly utilized.

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non- Wi-Fi data.

Example

The output of this example shows part of the channel metrics table for channels seen by the spectrum monitor ap123:

```
(host) [mynode] #show ap spectrum channel-metrics ap-name ap123 freq-band
2.4ghz

Channel Metrics Table
-----
Channel  Quality(%)  Availability(%)  Utilization(%)  WiFi Util(%)
Interference Util(%)
-----
1         97             57              43              40              3
2         80             58              42              22              20
3         63             58              42              5               37
4         71             57              43              16              27
5         88             54              46              36              10
6         98             51              49              47              2
7         88             54              46              35              11
8         69             56              44              14              30
9         60             57              43              3               40

11        0              0               100             0               100
12        25             50              50              0               50
13        50             99              1               0               1
14        99             99              1               0               1
1+/5-    63             54              46              36              10
2+/6-    63             51              49              47              2
3+/7-    63             51              49              47              2
4+/8-    69             51              49              47              2
5+/9-    60             51              49              47              2
6+/10-   30             29              71              1               70
7+/11-   0              0               100             0               100
```

The output of this command includes the following information:

Column	Description
channel	An 802.11a or 802.11g radio channel.

Column	Description
Quality(%)	Current relative quality of selected channels in the 802.11a or 802.11g radio bands, as determined by the percentage of packet retries, the current noise floor, and the duty cycle for non- Wi-Fi devices on that channel.
Availability(%)	The percentage of the channel currently available for use.
Utilization(%)	The percentage of the channel being used.
WiFi Util(%)	The percentage of the channel currently being used by Wi-Fi devices.
Interference Util(%)	The percentage of the channel currently being used by non-Wi-Fi interference + Wi-Fi ACI (Adjacent Channel Interference)

Related Commands

Command	Description
ap spectrum local-override	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.
rf dot11a-radio-profile mode spectrum-mode	Sets an 802.11a radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.
rf dot11g-radio-profile mode spectrum-mode	Sets an 802.11g radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.

Command History

Release	Modification
ArubaOS 8.9.0.0	The <code>6ghz</code> sub-parameter was introduced for <code>freq-band</code> parameter. (For ArubaOS 8.9.0.0 or later versions)
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap spectrum channel-summary

```
show ap spectrum channel-summary {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [freq-band {2.4ghz | 5ghz | 6ghz}]
```

Description

This command displays a summary of the 802.11a or 802.11g channels seen by a spectrum monitor.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor for which you want to view spectrum information.
freq-band {2.4ghz 5ghz} (For versions prior to ArubaOS 8.9.0.0)	View information for a specific radio type, either 2.4 GHz or 5 GHz.
freq-band {2.4ghz 5ghz 6ghz} (For ArubaOS 8.9.0.0 or later versions)	View information for a specific radio type, either 2.4 GHz, 5 GHz, or 6 GHz. NOTE: The 6ghz sub-

Parameter	Description
	parameter is applicable to Wi-Fi 6E APs only.

The output of the table can display data aggregate data for each channel seen by the spectrum monitor radio, including the maximum AP power, interference, and the Signal-to-Noise-and-Interference Ratio (SNIR).

SNIR is the ratio of signal strength to the combined levels of interference and noise on that channel. This value is calculated by determining the maximum noise-floor and interference-signal levels, and then calculating how strong the desired signal is above this maximum.

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non- Wi-Fi data.

Example

The output of the example below shows information for 802.11a radio channels seen by the spectrum monitor **ap999**.

```
(host) [mynode] #show ap spectrum channel-summary ap-name ap999 freq-band
5ghz

Channel Summary Table
-----
Channel   KnownAPs  UnknownAPs  Util(%)  MaxAPSignal (dBm)  MaxInterference
(dBm)    SNIR (dB)
-----
--  -----
149      69         0           5        -39              -69
 30
153      20         0          100       -42              -60
 18
157      56         0           6        -53              -59
  6
161      54         0           4        -43              -71
 28
165      32         0           3        -27              -70
 43
149+     69         0          100       -39              -60
 21
157+     20         0           6        -43              -59
 16
```

The output of this command includes the following information:

Column	Description
Channel	An 802.11a or 802.11g radio channel.
Known APs	Number of valid APs identified on the radio channel.
UnKnown APs	Number of invalid or rogue APs identified on the radio channel.
Channel Util (%)	Percentage of the channel currently in use.
Max AP Signal (dBm)	Signal strength of the AP that has the maximum signal strength on a channel.
Max Interference (dBm)	Signal strength of the non- Wi-Fi device that has the highest signal strength.
SNIR (db)	The ratio of signal strength to the combined levels of interference and noise on that channel. This value is calculated by determining the maximum noise-floor and interference-signal levels, and then calculating how strong the desired signal is above this maximum.

show ap spectrum client-list

```
show ap spectrum client-list {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [ap-bssid <ap-bssid> | channel <channel> | essid <essid> | freq-band {2.4ghz | 5ghz} | limit <limit> | mac <mac> | or | page <page> | sort <sort> | start <start>]
```

Description

This command shows details for clients seen by a specified spectrum monitor.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor for which you want to view spectrum information.
ap-bssid <ap-bssid>	View information for a client with a specific BSSID.
band <band>	View information for specific radio band. The possible values are 2.4ghz, 5ghz, or 6ghz.
channel <channel>	view information for clients on a specific radio channel.
essid <essid>	View information for clients using a specific ESSID.
mac <mac>	View information for a client with a specific MAC address.
or	Use this parameter to display information that meets either or two criteria, such as a specified ESSID or channel.
page <page>	Enter a number from 10–100 (inclusive) to specify the number of entries that should appear in each page of the output for this command. For example, if the output of this command has 100 entries and you select a page value of 20, the output will appear in 5 pages each with 20 entries. If you selected a page value of 10, the output would appear in 10 pages with 10 entries.
sort <sort>	Sort the output by the specified data column.
start <start>	Start displaying the output at specific spectrum index value.

Example

The following example shows that the spectrum monitor **ap999** sees eight different clients on channel 149. The output in the example below has been divided into two tables to better fit this document. In the ArubaOS CLI, the output appears as a single, long table.

```
(host) [mynode] #show ap spectrum client-list ap-name ap999 channel 149

The output of this command includes the following information:

Column	Description
mac	MAC address of the client.

Column	Description
bssid	Basic Service Set Identifier for a client. This is usually the device's MAC address.
essid	Extended service set identifier that names a wireless network.
spectrum-id	Identifier assigned to the client by the spectrum monitor.
chan	Radio channel used by the BSSID.
phy-type (For versions prior to ArubaOS 8.9.0.0)	Radio phy type. Possible types include: <ul style="list-style-type: none"> ▪ 802.11a ▪ 802.11a-HT-40 ▪ 802.11b/g ▪ 802.11b/g-HT-20
band (For ArubaOS 8.9.0.0 or later versions)	Radio band type. Possible types include: <ul style="list-style-type: none"> ▪ 2.4ghz ▪ 5ghz ▪ 6ghz (For Wi-Fi 6E APs)
signal (dBm)	Client signal strength, in dBm.
add-time	Time when the client was first detected by the spectrum monitor.

Column	Description
<code>last-seen</code>	Time when the spectrum monitor last detected that the client was active.

Related Commands

Command	Description
<code>ap spectrum local-override</code>	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.
<code>rf dot11a-radio-profilemodespectrum-mode</code>	Sets an 802.11a radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.

show ap spectrum debug

```
show ap spectrum debug {channel-info | channel-quality | classify |classify-device  
| classify-fft | device-details | device-info | devices-seen} {ap-name <ap-name> |  
ip-addr <ip-addr> | ip6-addr <ip6-addr>} freq-band {2.4ghz | 5ghz} radio {0 | 1 |  
2} [<count>]
```

Description

This command saves spectrum analysis channel information to a file on the spectrum monitor. Use this command under the supervision of your Aruba technical support representative to troubleshoot spectrum analysis issues or errors. If a dump-server is defined in the AP system profile of the AP, the file created by this command will be sent from the AP to the dump-server using TFTP.

Parameter	Description
channel-info	Save channel information for later analysis.
channel-quality	Save channel quality information for later analysis
classify	Save information on classification for later analysis.
classify-device	Save information on classification-related debugging with device-type for later analysis.
classify-fft	Save information on classification and FFT data for later analysis.
device-details	Save device details for later analysis.
device-info	Save device information for later analysis.
devices-seen	Save information on devices seen by the spectrum monitor.
ap-name <ap-name>	Name of the spectrum monitor for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor for which you want to view spectrum information.
freq-band {2.4ghz 5ghz}	Save information for a specific radio type, either 2.4 GHz or 5 GHz .
radio {0 1 2}	Save information for a specific radio type, either 0, 1, or 2 . Radio 0, 1 or 2 is supported only on AP-555 access points.
<count>	Specify the number of samples to save.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap spectrum debug channel-info ap-name ap-205 freq-band 2.4ghz 22
```

Related Commands

Command	Description
ap spectrum local-override	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.
rf dot11a-radio-profilemodespectrum-mode	Sets an 802.11a radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.
rf dot11g-radio-profilemodespectrum-mode	Sets an 802.11g radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.

Command History

Release	Modification
ArubaOS 8.6.0.0	The parameter <code>radio {0 1 2}</code> was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap spectrum debug fft

```
show ap spectrum debug fft {ap-name <ap-name> | ip-addr <ip-addr>} | ip-6 addr <ip6-addr>} freq-band {2.4ghz | 5ghz} [avg | duty-cycle | fft-to-controller | max | normalized | raw | raw-normalized] [<count>]
```

Description

This command helps you save Fast Fourier Transform (FFT) power data to a file on the spectrum monitor. Use this command under the guidance of your Aruba technical support representative to troubleshoot FFT power issues.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor.
freq-band {2.4ghz 5ghz}	Save information for a specific radio type, either 2.4 GHz or 5 GHz .
avg	Save FFT average information.
duty-cycle	Save FFT duty-cycle data.
fft-to-controller	Save the FFT max, average, and duty-cycle data.
max	Save the maximum FFT power measured for all samples taken over the last second.
normalized	Save normalized FFT information.
raw	Save the raw FFT information received from a driver.
raw-normalized	Save FFT information received from a driver and its normalized FFT.
count	Save a specific number of samples.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap spectrum debug fft ap-name ap-205 freq-band 5ghz avg 20
```

Related Commands

Command	Description
ap spectrum local-override	Convert an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.
rf dot11a-radio-profile mode spectrum-mode	Set an 802.11a radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.
rf dot11g-radio-profile mode spectrum-mode	Set an 802.11g radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.

Command History

Release	Modification
ArubaOS 8.6.0.0	The output displays the details of Radio 0, 1 and 2 for AP-555 access points.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap spectrum debug status

```
show ap spectrum debug status {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [freq-band {2.4ghz | 5ghz | 6ghz}]
```

Description

This command shows detailed status and statistics for a spectrum monitor or hybrid AP. Use the command under the guidance of an Aruba technical support representative to troubleshoot spectrum analysis errors.

Parameter	Description
ap-name <ap-name>	Name of the spectrum device for which you want to view status information.
ip-addr <ip-addr>	IP address of the spectrum device for which you want to view status information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum device for which you want to view status information.
freq-band {2.4ghz 5ghz} (For versions prior to ArubaOS 8.9.0.0)	View information for a specific radio type, either 2.4 GHz or 5 GHz.
freq-band {2.4ghz 5ghz 6ghz} (For ArubaOS 8.9.0.0 or later versions)	View information for a specific radio type, either 2.4 GHz, 5 GHz, or 6 GHz. NOTE: The 6ghz sub-parameter is applicable to Wi-Fi 6E APs only.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap spectrum debug status ap-name ap-205 freq-band 5ghz
```

Related Commands

Command	Description
ap spectrum local-override	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.

Command	Description
rf dot11a-radio-profilemodespectrum-mode	Sets an 802.11a radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.
rf dot11g-radio-profilemodespectrum-mode	Set an 802.11g radio so that the device operates as a spectrum monitor and can send spectrum analysis data to a desktop or laptop client.

Command History

Release	Modification
ArubaOS 8.9.0.0	The <code>6ghz</code> sub-parameter was introduced for <code>freq-band</code> parameter. (For ArubaOS 8.9.0.0 or later versions)
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap spectrum device-duty-cycle

```
show ap spectrum device-duty-cycle {ap-name <ap-name>| ip-addr <ip-addr> | ip6-addr <ip6-addr>} [freq-band {2.4ghz | 5ghz}] radio {0 | 1 | 2}
```

Description

This command shows the current duty cycle for devices on all channels being monitored by the spectrum monitor or hybrid AP radio.

Parameter	Description
ap-name <ap-name>	Name of the spectrum device for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum device for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum device for which you want to view spectrum information.
freq-band 2.4ghz 5ghz	View information for a specific radio type, either 2.4 GHz or 5 GHz.
radio {0 1 2}	View information for a specific radio type, either 0, 1 or 2. Radio 0, 1 or 2 is supported only on AP-555 access points.

The FFT Duty Cycle table in the output of this command shows the duty cycle for each radio channel. The duty cycle is the percentage of time each device type operates or transmits on that channel. For additional details about non- Wi-Fi device types shown in this table, see [Non-Wi-Fi Interferers on page 2433](#).

Examples

The output of this command shows that video devices sent a signal on channels 153 and 157 during 99% of the last sample interval:

```
Device Duty Cycle Table (in %)
-----
Device Type          149  153  157  161  165  149+  157+
-----
Generic Interferer   0    0    0    0    0    0    0
WIFI                  5    0    5   12    8    0   12
Microwave             0    0    0    0    0    0    0
Bluetooth             0    0    0    0    0    0    0
Generic Fixed Freq    0    0    0    0    0    0    0
Cordless Phone FF    0    0    0    0    0    0    0
Video                 0   99   99    0    0    0    0
```

```

Audio          0  0  0  0  0  0  0
Generic Freq Hopper 0  0  0  0  0  0  0
Cordless Network FH 0  0  0  0  0  0  0
Xbox           0  0  0  0  0  0  0
Microwave Inverter 0  0  0  0  0  0  0

```
show ap spectrum device-history {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [freq-band {2.4ghz | 5ghz | 6ghz}] [type {audio | bluetooth | cordless-ff-phone | cordless-fh-base | cordless-fh-network | generic-ff | generic-fh | generic-interferer | microwave | microwave-inverter | video | xbox}]
```

Description

This command shows the history of the last 256 non-Wi-Fi devices. Use this command to view channel, signal, and duty-cycle information as well as add or delete times for the last 256 devices seen by a spectrum monitor or hybrid AP.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
freq-band {2.4ghz 5ghz} (For versions prior to ArubaOS 8.9.0.0)	View information for a specific radio type, either 2.4 GHz or 5 GHz.

Parameter	Description
<p>freq-band {2.4ghz 5ghz 6ghz} (For ArubaOS 8.9.0.0 or later versions)</p>	<p>View information for a specific radio type, either 2.4 GHz, 5 GHz, or 6 GHz.</p> <p>NOTE: The 6ghz sub-parameter is applicable to Wi-Fi 6E APs only.</p>

Parameter	Description
cordless-fh-base	View information for frequency-hopping cordless phone bases seen by the spectrum device.
cordless-fh-network	View information for frequency-hopping cordless network devices seen by the spectrum device.
generic-ff	View information for generic fixed-frequency devices seen by the spectrum device.
generic-fh	View information for generic frequency-hopping devices seen by the spectrum device.
generic-interferer	Show only generic interfering devices.
microwave	View information for microwave-emitting devices seen by the spectrum device. NOTE: This option is available only for 2.4 GHz

Parameter	Description
	spectrum devices.
microwave-inverter	View information for inverter microwave devices seen by the spectrum device. NOTE: This option is available only for 2.4 GHz spectrum devices.
video	View information for video devices seen by the spectrum device.
xbox	View information for Xbox devices seen by the spectrum device. NOTE: This option is available only for 2.4 GHz spectrum devices.

Non-Wi-Fi Interferers

The following table describes each type of non-Wi-Fi interferer detected by a spectrum monitor or hybrid AP. Note also that a hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

Non-Wi-Fi Interferer Type	Description
Bluetooth	Any device that uses the Bluetooth protocol to communicate in the 2.4 GHz band is classified as a <i>Bluetooth</i> device. Bluetooth uses a frequency hopping protocol.
Fixed Frequency (Audio)	Some audio devices such as wireless speakers and microphones also use fixed frequency to continuously transmit audio. These devices are classified as <i>Fixed Frequency (Audio)</i> .
Fixed Frequency (Cordless Phones)	Some cordless phones use a fixed frequency to transmit data (much like the fixed frequency video devices). These devices are classified as <i>Fixed Frequency (Cordless Phones)</i> .
Fixed Frequency (Video)	Video transmitters that continuously transmit video on a single frequency are classified as <i>Fixed Frequency (Video)</i> . These devices typically have close to a 100% duty cycle. These types of devices may be used for video surveillance, TV, or other video distribution, and similar applications.
Fixed Frequency (Other)	All other fixed frequency devices that do not fall into one of the above categories are classified as <i>Fixed Frequency (Other)</i> . Note that the RF signatures of the fixed frequency audio, video, and cordless phone devices are very similar and that some of these devices may be occasionally classified as Fixed Frequency (Other).
Frequency Hopper (Cordless Base)	Frequency hopping cordless phone base units transmit periodic beacon-like frames at all times. When the handsets are not transmitting (i.e., no active phone calls), the cordless base is classified as <i>Frequency Hopper (Cordless Base)</i> .
Frequency Hopper (Cordless Network)	When there is an active phone call and one or more handsets are part of the phone conversation, the device is classified as <i>Frequency Hopper (Cordless Network)</i> . Cordless phones may operate in 2.4 GHz or 5 GHz bands. Some phones use both 2.4 GHz and 5 GHz bands (for example, 5 GHz for Base-to-handset and 2.4 GHz for Handset-to-base). These phones may be classified as unique Frequency Hopper devices on both bands.
Frequency Hopper (Xbox)	The Microsoft Xbox device uses a frequency hopping protocol in the 2.4 GHz band. These devices are classified as <i>Frequency Hopper (Xbox)</i> .
Frequency Hopper (Other)	When the classifier detects a frequency hopper that does not fall into one of the above categories, it is classified as Frequency Hopper (Other). Some examples include IEEE 802.11 FHSS devices, game consoles, and cordless or hands-free devices that do not use one of the known cordless phone protocols.

Non-Wi-Fi Interferer Type	Description
Microwave	Common residential microwave ovens with a single magnetron are classified as a <i>Microwave</i> . These types of microwave ovens may be used in cafeterias, break rooms, dormitories, and similar environments. Some industrial, healthcare, or manufacturing environments may also have other equipment that behave like a microwave and may also be classified as a Microwave device.
Microwave (Inverter)	Some newer-model microwave ovens have the inverter technology to control the power output and these microwave ovens may have a duty cycle close to 100%. These microwave ovens are classified as <i>Microwave (Inverter)</i> . Dual-magnetron industrial microwave ovens with higher duty cycle may also be classified as Microwave (Inverter). As in the Microwave category described above, there may be other equipment that behave like inverter microwaves in some industrial, healthcare, or manufacturing environments. Those devices may also be classified as Microwave (Inverter).
Generic Interferer	Any non-frequency hopping device that does not fall into one of the other categories described in this table is classified as a <i>Generic Interferer</i> . For example, a Microwave-like device that does not operate in the known operating frequencies used by the Microwave ovens may be classified as a Generic Interferer. Similarly wide-band interfering devices may be classified as Generic Interferers.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ap spectrum device-history ap-name ap-205 type audio
```

The output of this example shows details for fixed-frequency video devices seen by a spectrum monitor or hybrid AP radio:

```
host) [mynode] #show ap spectrum device-history ap-name ap123 freq-band 5ghz
type video

The output of this command includes the following information:

Column	Description
Type	<p>Device type. This parameter can be any of the following:</p> <ul style="list-style-type: none"> ▪ audio FF (fixed frequency) ▪ bluetooth ▪ cordless base FH (frequency hopper) ▪ cordless phone FF (fixed frequency) ▪ cordless network FH (frequency hopper) ▪ generic FF (fixed frequency) ▪ generic FH (frequency hopper) ▪ generic interferer ▪ microwave ▪ microwave inverter ▪ video ▪ xbox <p>NOTE: For additional details about non- Wi-Fi device types shown in this table, see Non-Wi-Fi Interferers on page 2433.</p>
ID	ID number assigned to the device by the spectrum monitor or hybrid AP radio. Spectrum monitors and hybrid APs assign a unique spectrum ID per device type.
Cfreq	Center frequency of the signal sent from the device.
Bandwidth	Channel bandwidth used by the device, in KHz.
Channels-affected	Radio channels affected by the wireless device, in KHz.
Signal-strength	Strength of the signal sent from the device, in dBm.

Column	Description
Duty-cycle	Device duty cycle. This value represents the percent of time the device broadcasts on the specified channel or frequency.
Add-time	Time at which the device was first detected.
Delete-time	Time at which the device was aged out.

Related Commands

show ap spectrum device-log

```
show ap spectrum device-log {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} [freq-band {2.4ghz | 5ghz | 6ghz} [type {audio | bluetooth | cordless-ff-phone | cordless-fh-base | cordless-fh-network | generic-ff | generic-fh | generic-interferer | microwave | microwave-inverter | video | xbox}]
```

Description

This command shows a time log of add and delete events for non-Wi-Fi devices.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor for hybrid AP or which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip6-addr <ip6-addr>	IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
freq-band {2.4ghz 5ghz} (For versions prior to ArubaOS 8.9.0.0)	View information for a specific radio type, either 2.4 GHz or 5 GHz.
freq-band {2.4ghz 5ghz 6ghz} versions) (For ArubaOS 8.9.0.0 or later)	View information for a specific radio type, either 2.4 GHz, 5 GHz, or 6 GHz.

Parameter	Description
	<p>NOTE: The 6ghz sub-parameter is applicable to Wi-Fi 6E APs only.</p>
type	Show data for a specific device type only.
audio	Show only audio fixed frequency devices.
bluetooth	<p>Show only Bluetooth devices.</p> <p>NOTE: This option is available only for 2.4 GHz spectrum device radios.</p>
cordless-ff-phone	View information for frequency-hopping cordless phones seen by the spectrum device.
cordless-fh-base	View information for frequency-hopping cordless phone bases seen by the spectrum device.

Parameter	Description
cordless-fh-network	View information for frequency-hopping cordless network devices seen by the spectrum device.
generic-ff	View information for generic fixed-frequency devices seen by the spectrum device.
generic-fh	View information for generic frequency-hopping devices seen by the spectrum device.
generic-interferer	Show only generic interfering devices.
microwave	<p>Show only microwave devices.</p> <p>NOTE: This option is available only for 2.4 GHz spectrum device radios.</p>
microwave-inverter	<p>Show only microwave inverter devices.</p> <p>NOTE: This option is available only for 2.4 GHz spectrum</p>

Parameter	Description
	device radios.
video	Show only video fixed frequency devices.
xbox	Show only Xbox frequency hopper devices. NOTE: This option is available only for 2.4 GHz spectrum device radios.

A hybrid AP on a 20 MHz channel will see 40 MHz Wi-Fi data as non-Wi-Fi data.

Example

The output of this example shows that the spectrum monitor **ap123** logged data for four frequency-hopping cordless base devices seen by its 802.11g radio. Note that the output below is divided into two sections to better fit on the page of this document. In the ArubaOS CLI, this information is displayed in a single long table.

```

The output of this command includes the following information:

Column	Description
Device Type	Type of non-Wi-Fi device detected by the spectrum monitor or hybrid AP
ID	The spectrum ID number assigned to that device. Spectrum monitors and hybrid APs assign a unique spectrum ID per device type.
Added/Deleted	The non-Wi-Fi Device Log table can show signal data for a device when that device was added or removed from the log table.
Signal Strength	Strength of the signal sent by the device.
Duty Cycle	Device duty cycle. This value represents the percent of time a signal is broadcast on a specific channel or frequency.
Center Freq	Center frequency of the signal sent by the device.
Start Freq	Lowest signal frequency sent by the device.
End Freq	Highest signal frequency sent by the device.
Channels affected	Radio channels affected by the device signal.
Bandwidth	Amount of signal bandwidth used by the device, in Kilohertz.

show ap spectrum device-summary

```
show ap spectrum device-summary
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
  freq-band {2.4 GHz | 5 GHz}
```

Description

This command shows the numbers of Wi-Fi and non-Wi-Fi device types on each channel monitored by a spectrum monitor or hybrid AP. Use this command to show the types of devices that the spectrum device can detect on each channel it monitors. For additional details about non-Wi-Fi device types shown in this table, see [Non-Wi-Fi Interferers on page 2433](#).

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
freq-band {2.4ghz 5ghz}	View information for a specific radio type, either 2.4 GHz or 5 GHz.

Example

The output of this example shows that the spectrum monitor **ap123** is able to detect 61 Wi-Fi devices on channel 149:

```
(host) [mynode] #show ap spectrum device-summary ap-name ap123 freq-band
5ghz

show ap spectrum interference-power

```
show ap spectrum interference-power
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
  freq-band {2.4ghz | 5ghz | 6ghz}
  <chan-width>
```

Description

This command shows the interference power detected by a 802.11a or 802.11g radio on a spectrum monitor or hybrid AP. This table displays information about AP power levels, channel noise, and adjacent channel interference seen on each channel by a spectrum monitor or hybrid AP radio.

The output of this command displays the noise floor of each selected channel in dBm. The noise floor of a channel depends on the noise figure of the RF components used in the radio, temperature, presence of certain types of interferers or noise, and the width of the channel. For example, in a clean environment, the noise floor of a 20 MHz channel will be around -95 dBm and that of a 40 MHz channel will be around -92 dBm. Certain types of fixed frequency continuous transmitters such as video bridges, fixed frequency phones, and wireless cameras typically elevate the noise floor as seen by the Wi-Fi radio. Other interferers such as the frequency hopping phones, Bluetooth, and Xbox devices may not affect the noise floor of the radio. A Wi-Fi radio can only reliably decode Wi-Fi signals that are a certain dB above the noise floor and therefore estimating and understanding the actual noise floor of the radio is critical to understanding the reliability of the RF environment.

The ACI column displayed in the Interference Power Chart displays Adjacent-Channel Interference (ACI) power levels based on the signal strength(s) of the Wi-Fi APs on adjacent channels. A higher ACI value in Interference Power Chart does not necessarily mean higher interference since the AP that is contributing to the maximum ACI may or may not be very actively transmitting data to other clients at all times. The ACI power levels are derived from the signal strength of the beacons.

Parameter	Description
ap-name <ap-name>	Name of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip-addr <ip-addr>	IP address of the spectrum monitor or hybrid AP for which you want to view spectrum information.
ip6-addr <ip6-addr>	IPv6 address of the spectrum monitor or hybrid AP for which you want to view spectrum information.

Parameter	Description
freq-band {2.4ghz 5ghz} (For versions prior to ArubaOS 8.9.0.0)	View information for a specific radio type, either 2.4 GHz or 5 GHz.
freq-band {2.4ghz 5ghz 6ghz} (For ArubaOS 8.9.0.0 or later versions)	View information for a specific radio type, either 2.4 GHz, 5 GHz, or 6 GHz. NOTE: The 6ghz sub-parameter is applicable to Wi-Fi 6E APs only.

Example

The output of this example shows interference power levels for each channel seen by the spectrum monitor **ap123**:

```
(host) [mynode] #show ap spectrum interference-power ap-name ap123 freq-band 5ghz

00:24:6c:81:57:c8 -0           -60
```

The output of this command includes the following information:

Column	Description
Channel	An 802.11a or 802.11g radio channel.
Noise Floor (dBm)	Current noise floor recorded on the channel.
Max AP Signal (dBm)	Power level of the AP on the channel with the highest signal power.

Column	Description
Max AP SSID	SSID of the AP on the channel with the highest signal power.
Max AP BSSID	BSSID of the AP on the channel with the highest signal power.
ACI (dBm)	Adjacent channel interference level detected by the spectrum device.
Max Interference Power (dBm)	Signal strength of the non-Wi-Fi device that has the highest signal strength.

show ap spectrum-load-balancing

```
show ap spectrum-load-balancing
  group <group>
```

Description

This command shows spectrum load balancing information for an AP with this feature enabled.

Parameter	Description
group <group>	Filter this information to show only data for the specified spectrum load balancing domain.

Example

The output of the command below shows the APs currently using the spectrum load-balancing domain **default-1**:

```
(host)[mynode] #show ap spectrum-load-balancing group default-1

Spectrum Load Balancing Group
-----
Name          IP Address      Domain      Assignment  Clients
-----
ap121-1      192.168.151.253 default-1   149/21      3
ap124-1      192.168.151.254 default-1   48/15      3
ap125-1      192.168.151.251 default-1   44/15      2
```

The output of this command includes the following information:

Column	Description
Name	Name of an AP.
IP address	IP address of the AP.
Domain	Name of the spectrum load balancing domain assigned to the AP.
Assignment	Current channel and power assignment for the AP.
Clients	Number of clients currently using the AP.

show ap spectrum local-override

show ap spectrum local-override

Description

This command shows a list of AP radios currently converted to spectrum monitors through the spectrum local-override list.

Example

The output of this example shows that three APs each have two radios defined as spectrum monitors:

```
(host)[mynode] #show ap spectrum local-override
Spectrum Local Override Profile
-----
Parameter      Value
-----
Override Entry  AP ap125 band 2ghz
Override Entry  AP ap125 band 5ghz
Override Entry  AP ap105 band 2ghz
Override Entry  AP ap105 band 5ghz
Override Entry  AP apcorp1 band 2ghz
Override Entry  AP APcorp1 band 5ghz
```

The Value column in the output of this command includes the following information:

Parameter	Description
Override Entry	Indicates that an AP radio has been added to the local override list.
Value	Radio that has been added to the override list and the band used by that radio.

Related Commands

Command	Description
ap spectrum local-override	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.

show ap spectrum monitors

```
show ap spectrum monitors
  ap-group <ap-group>
  ap-name <ap-name>
  ap-type <ap-type>
  channel <channel>
  freq-band <freq-band>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
  or
  page <page>
  sort <sort>
```

Description

This command shows a list of APs terminating on the controller that are currently configured as spectrum monitors or hybrid APs.

Parameter	Description
ap-group <ap-group>	Specify the spectrum device's AP group.
ap-name <ap-name>	Specify the AP name configured as a spectrum monitor or hybrid AP.
ap-type <ap-type>	Specify the AP type.
channel <channel>	Specify the channel of hybrid monitor.
freq-band <freq-band>	Specify the frequency band.
ip-addr <ip-addr>	Specify the IP address of spectrum monitor.
ip6-addr <ip6-addr>	Specify the IPv6 address of spectrum monitor.
or	Show spectrum monitors that satisfy any of the given conditions:
page <page>	Enter a value greater than 1 for Page Number. The number of spectrum monitors displayed per page is 50.
sort <sort>	Sort criteria based on pairs of column name and order, e.g. ap-name,asc,channel,desc, and so on.

Example

The output of this example shows that the 802.11a radio on a spectrum monitor named **ap123** is sending spectrum analysis data to a client with the IP address 10.240.16.177.

```
(host) [mynode] #show ap spectrum monitors

List of Spectrum Monitors
-----
AP name          Group    AP Type  Phy  Band      Channel  Mode
-----
Client IP        Subscribe Time
-----
00:24:6c:c0:0c:89 default  105     G    2GHz      1         Access Point
00:24:6c:c0:0c:89 default  105     A    5GHz      44+       Access Point
10.240.16.177    2011-01-21 07:17:57 AM
00:24:6c:c7:d6:1c default  93      A    5GHz      -         Spectrum
Monitor 10.240.16.177 2011-01-21
07:18:22 AM
```

The output of this command includes the following information:

Column	Description
AP name	Name of an AP configured as a spectrum monitor or hybrid AP.
Group	Name of the spectrum device's AP group.
Ap Type	The AP model number .
Phy	The radio's PHY type. Possible values are A for 802.11a and G for 802.11b/g,
Band	Spectrum band that the spectrum monitor or hybrid AP radio is currently monitoring.
Mode	This column shows whether the device is an access point configured as a hybrid AP or a spectrum monitor.
Client IP	IP address of the client to which the spectrum monitor or hybrid AP is sending data.
Subscribe time	Time at which the spectrum monitor or hybrid AP was connected to the client.

Related Commands

show ap spectrum tech-support

```
show ap spectrum tech-support
  ap-name <ap-name>
  <filename>
```

Description

Saves spectrum data for later analysis by technical support. Use this command under the supervision of your Aruba technical support representative to troubleshoot spectrum analysis issues or errors.

Parameter	Description
ap-name <ap-name>	Saves technical support information for a specific spectrum monitor.
<filename>	Name of the file to which this data should be saved. This file does not have to already exist on the controller, the <code>show ap spectrum technical-support</code> command will create this file.

show ap standby

```
show ap standby
  ap-name <ap-name>
  bssid <bssid>
  details
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

Shows all APs in standby mode currently registered to a managed device. This command displays details for all APs connected to a controller in standby mode.

Parameter	Description
ap-name <ap-name>	View data for an AP with a specified name.
bssid <bssid>	View data for a specific BSSID.
details	View AP data detailed columns.
ip-addr <ip-addr>	View data for an AP with a specified IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	View data for an AP with a specified IPv6 address.

Example

Issue the following command to view AP data detailed columns:

```
(host) [mynode] #show ap standby

Standby AP Table
-----
Name      Group      IP Address      AP Type  Flags  Uptime      Outer IP

The output of this command includes the following information:

Column	Description
RF Band	For dual-band radios, this parameter displays the RF band in which the AP should operate: <ul style="list-style-type: none"> ▪ g = 2.4 GHz ▪ a = 5 GHz

Column	Description
Recovery Mode	Displays the AP behavior when a firmware assert is detected.
RF Band for AM mode scanning	Scanning band for multiple RF radios. <ul style="list-style-type: none"> ▪ g = 2.4 GHz ▪ a = 5 GHz ▪ all = Radio scans both bands. This is the default setting.
Native VLAN ID	Native VLAN for bridge mode virtual APs (frames on the native VLAN are not tagged with 802.1q tags).
WIDS AMPDU Optimization	Displays if the WIDS aggregate MPDU optimization is enabled or disabled.

Column	Description
Tunnel Heartbeat Interval	Interval between heartbeat messages between a remote or campus AP and its associated managed device. An increase in the heartbeat interval increases the time it will take for an AP to detect the loss in connectivity to the managed device, but can reduce Internet bandwidth consumed by a remote AP.
Session ACL	This parameter shows the ACL applied on the uplink of a remote AP.
Corporate DNS Domain	DNS name used by the corporate network.
SNMP sysContact	SNMP system contact information.
LED operating mode	Displays the LED operating mode for indoor 802.11n APs. LEDs display as usual in the default normal operating mode, but are all turned off in off mode.

Column	Description
	NOTE: If the LMS-IP is blank, the access point will remain on the managed device that it finds using methods like DNS or DHCP. If an IP address is configured for the LMS IP parameter, the AP will be immediately redirected to the managed device at that address.
Backup LMS IP	For networks with multiple managed devices, this parameter displays the IP address of a backup to the IP address specified with the lms-ip parameter.

Column	Description
LMS IPv6	For IPv6 networks with multiple managed devices, this parameter specifies the IPv6 address of the local management switch (LMS)—the Aruba managed device—which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. This can be the IP address of the managed device or Mobility Conductor.
Backup LMS IPv6	In multi-controller IPv6 networks, this parameter specifies the IPv6 address of a backup to the IPv6 address specified with the LMS IPv6 setting.
LMS Preemption	When this parameter is enabled, the local management switch automatically reverts to the primary LMS IP address when it becomes available.

Column	Description
LMS Hold-down Period	<p>Time, in seconds, that the primary LMS must be available before an AP returns to that LMS after failover. The <code>rap-dhcp-server-vlan</code> VLAN ID of the remote AP DHCP server is used if the managed device is unavailable. This VLAN enables the DHCP server on the AP (also known as the remote AP DHCP server VLAN). If you enter the native VLAN ID, the DHCP server is unavailable.</p>
LMS ping interval	<p>The interval at which an application level ping is sent to a primary controller to check the reachability. Applicable only for RAPs.</p> <p>NOTE: If this parameter is changed, the UDP session timeout should be set accordingly on an intermediate router. The preferred timeout value is lms-ping-interval plus 30 seconds.</p>

Column	Description
Remote-AP DHCP Server VLAN	VLAN ID of the remote AP DHCP server used if the managed device is unavailable. This VLAN enables the DHCP server on the AP (also known as the remote AP DHCP server VLAN).
Remote-AP DHCP Server ID	IP address used as the DHCP server identifier.
Remote-AP DNS Server	IP address of the DNS server.
Remote-AP DHCP Default Router	IP address for the default DHCP router.
Remote-AP DHCP Pool Start	This parameter defines the starting IP address in the DHCP pool for remote APs.
Remote-AP DHCP Pool End	This parameter defines the last IP address in the DHCP pool for remote APs.
Remote-AP DHCP Pool Netmask	Configures a DHCP pool for remote APs. This is the netmask used for the DHCP pool.
Remote-AP uplink total bandwidth	This is the total reserved uplink bandwidth (in kilobits per second).

Column	Description
Remote-AP bw reservation 1 Remote-AP bw reservation 2 Remote-AP bw reservation 3	Session ACLs with uplink bandwidth reservation in kilobits per second. You can specify up to three session ACLs to reserve uplink bandwidth. The sum of the three uplink bandwidths should not exceed the rap-bw-total value.
Remote-AP Local Network Access	Shows if Remote-AP Local Network Access is enabled or disabled. By enabling this option, the clients that are connected to a remote AP can communicate. NOTE: By default, the Remote-AP Local Network Access will be disabled.
Flex Radio Mode	The mode for flexible radio.
Dual 5GHz Mode	The mode for dual 5 GHz APs.
Split-5GSHz Mode	The mode for split 5 GHz APs.

Column	Description
IPM activation	Displays the activation status of the Intelligent Power Monitoring (IPM) system.
Bootstrap threshold	Number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots. On the managed device, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.
Double Encrypt	This parameter applies only to remote APs. Double encryption is used for traffic to and from a wireless client that is connected to a tunneled SSID. When enabled, all traffic is re-encrypted in the IPsec tunnel. When disabled, the wireless frame is only encapsulated inside the IPsec tunnel.

Column	Description
Dump Server	(For debugging purposes.) Displays the server to receive the core dump generated if an AP process crashes.
Heartbeat DSCP	DSCP value of AP heartbeats (0-63).
Maintenance Mode	Shows if Maintenance mode is enabled or disabled. If enabled, APs stop flooding unnecessary traps and syslog messages to the NMS or network operations centers when deploying, maintaining, or upgrading the network. The managed device still generates debug syslog messages if debug logging is enabled.
Maximum Request Retries	Maximum number of times to retry AP-generated requests, including keepalive messages. After the maximum number of retries, the AP either tries the IP address specified by the bkup-lms-ip (if configured) or reboots.

Column	Description
Request Retry Interval	Interval, in seconds, between the first and second retries of AP-generated requests. If the configured interval is less than 30 seconds, the interval for subsequent retries is increased up to 30 seconds.
Number of IPSEC retries	The number of times the AP will attempt to recreate an IPsec tunnel with Mobility Conductor before the AP will reboot. A value of 0 disables the reboot.
AeroScout RTLS Server	<p>This parameter contains the following information, separated by colons:</p> <ul style="list-style-type: none"> ▪ IPv4 or IPv6 address of an AeroScout real-time asset location (RTLS) server to which locations report are sent. ▪ Port number: Port number on the

Column	Description
	<p>AeroScout server to which location reports are sent.</p> <ul style="list-style-type: none"> ▪ Include-unassoc-sta: Specifies whether to include unassociated stations when sending station reports. Unassociated stations are stations that are not associated to any AP <p>Default: Disabled</p>
RTLS Server configuration	<p>This parameter contains the following information, separated by colons.</p> <ul style="list-style-type: none"> ▪ IPv4 or IPv6 address of the RTLS server to which the AP sends RFID tag information. ▪ Number of the RTLS server port to which the

Column	Description
	<p>AP sends RFID tag information.</p> <ul style="list-style-type: none"> ▪ Shared secret key for the server. ▪ Frequency at which packets are sent to the server, in seconds.
AP USB Power mode	<p>Displays the status of USB port on various AP platforms that have external USB ports. Listed below are the power modes:</p> <ul style="list-style-type: none"> ▪ auto: Detect USB power mode automatically. ▪ disable: Disable USB power. ▪ enable: Enable USB power. <p>NOTE: This parameter can be configured only on AP-214, AP-215, AP-224, AP-225, AP-205H, AP-303H, AP-304, AP-305, AP-314, AP-315, AP-324, AP-325, AP-334, AP-335, AP-344, AP-345, AP-203R, and AP-203RP access</p>

Column	Description
	points only.
Telnet	Reports whether telnet access to the AP is enabled or disabled.
RF Band for Backup	If the system profile is enabled, the AP console accesses using a backup ESSID.
Operation for Backup	This parameter allows AP console access using a backup ESSID, allowing users to access an AP console after the AP has disconnected from the managed device. When the AP advertises a backup ESSID in either static or dynamic mode, an user is able to access and debug the AP remotely through a virtual AP. This feature is disabled by default.
BLE Endpoint URL	Displays the URL of the Meridian server to which the Bluetooth Low Energy (BLE) sends monitoring data.

Column	Description
BLE Auth Token	Displays the BLE endpoint authorization token. This token is unique for each deployment.
BLE Operation Mode	Displays the BLE operation mode of the AP.
Wired Port Down-Time By Shutdown Ethernet Link	Displays the amount of time the AP needs to keep the Ethernet link of the wired port in down state after failover to backup cluster or fallback to primary cluster. NOTE: The port bounce feature is disabled when the value is 0.
Wired Port Down-Time By Shutdown POE	Displays the amount of time the AP needs to keep the PoE of the wired port in down state after failover to backup cluster or fallback to primary cluster. NOTE: The port bounce feature is disabled when the value is 0.

Starting from ArubaOS 8.2.0.0, the output of the `show ap system-profile <profile-name> | include IPM` command is modified to display a new output parameter, IPM Steps delete all.

```
(host) [mynode] #show ap system-profile default | include IPM
IPM activation                               Disabled
IPM power reduction steps with priorities    N/A
```

IPM Steps delete all No

Starting from ArubaOS 8.4.0.0, the output of the `show ap system-profile <profile-name> | include USB` command is modified to display a new output parameter, `AP USB Power mode`.

```
(host) [mynode] #show ap system-profile default | include USB
AP USB Power mode          auto
```

Related Commands

Command	Description

show ap tech-support

```
show ap tech-support ap-name <ap-name> [<filename>]
```

Description

This command displays all information for an AP, or saves that information to a file on the controller. This information can be used by Aruba technical support to diagnose a problem with an AP. Aruba technical support may request that you issue this command to help analyze and troubleshoot problems with an AP or your wireless network.

Parameter	Description
<ap-name>	Name of the AP for which you want to view tech support data.
<filename>	Save the output of this command to a file on the controller with the specified filename.

show ap vht-rates

```
show ap vht-rates bssid <bssid>
```

Description

Shows Very-High-Throughput (VHT) rates for an AP that supports 802.11ac.

Parameter	Description
bssid <bssid>	Shows VHT rates for a specific Basic Service Set Identifier (BSSID) on an 802.11ac-capable AP. The Basic Service Set Identifier (BSSID) is usually the MAC address of the AP radio.

Example

The output of the command below shows very-high-throughput rates for 20 MHz, 40 MHz, and 80 MHz data streams with and without a Short Guard Interval (SGI).

```
(host) [mynode] #show ap vht-rates bssid 6c:f3:7f:e7:51:f0
AP "Corp-ac" Radio 0 BSSID 6c:f3:7f:e7:51:f0 Very-high-throughput Rates

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
This command will only show rate information for 802.11ac-capable APs.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap virtual-beacon-report

```
show ap virtual-beacon-report {all | ap-name <ap-name> | client-mac <client-mac> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

If the Client Match feature is enabled, the output of this command displays the virtual beacon report for an AP or a client with a specific IP or MAC address. Use this command to display the client RSSI from the APs in its RF neighborhood, the channel used by each AP radio, and the number of clients associated to each radio.

Parameter	Description
all	Virtual beacon report for all clients on the controller.
ap-name <ap-name>	Name of the AP for which you want to view a virtual beacon report.
client-mac <client-mac>	MAC address of a client for which you want to view a virtual beacon report.
ip-addr <ip-addr>	IPv4 address of an AP for which you want to view a virtual beacon report.
ip6-addr <ip6-addr>	IPv6 address of an AP for which you want to view a virtual beacon report.

Examples

The following example displays the virtual beacon report for a client with MAC address 48:e2:44:b1:8a:95:

```
(host) [mynode] #show ap virtual-beacon-report client-mac 48:e2:44:b1:8a:95

```

The output of this command includes the following parameters:

Parameter	Description
Client MAC	MAC address of the client.
Current association	MAC address of the AP radio to which the client is currently associated.
Steer attempts/Success	Number of steer attempts and the number of successful steers.
Consecutive (Fails/BTM Rej/BTM Timeouts)	Consecutive number of failed steer attempts, rejected BSS Transition Management Requests, and BSS Transition Management timeouts.
Bandsteer window (Steers/Start time/Expiry time)	Number of band steers, the start time of the band steer, and the expiry time of the band steer.
Client Device Type	Type of device used by the client (for example, Windows).
Current State	Indicates whether the client is currently steerable.

Parameter	Description
Client Supported Channels	Lists the channels that support client use.
Current Time	Timestamp showing the current date and time.
AP	Name of the AP from which the client can detect a signal.
IP address	IPv4 or IPv6 address of the AP from which the client can detect a signal.
Radio	MAC address of the AP radio from which the client can detect a signal.
ESSID	Identifying name of the wireless network for each AP.
Signal (dBm)	Signal strength, in dBm, from the AP radio.
Last Update	Time that the virtual beacon report last updated information for the AP radio.
Add Time	Date and time the client is successfully steered and added to the AP.
Channel/EIRP/Clients	Channel used by the AP radio, the amount of power transmitted from the AP antennae, and the number of clients associated to it.
Flag	<p>The output of this column shows the following values:</p> <ul style="list-style-type: none"> ▪ *: Flag indicating that the client is currently associated to this AP ▪ S: Flag indicating a stale entry, with the last client update from this radio produced 120+ seconds ago ▪ U: Flag indicating that the client does not support the channel the radio is currently operating on

The following example displays a virtual beacon report for all clients in the network:

```
(host) [mynode] #show ap virtual-beacon-report all
```

```

Client MAC :60:d9:c7:a2:42:cb

```

The output of this command includes the additional `Active Media Sessions` parameter, which indicates whether the client is involved in any active media sessions.

Related Commands

Command	Description
rf arm-profile	Configures the Adaptive Radio Management (ARM) profile.
show ap arm client-match probe-report	Displays additional statistics for the Client Match feature.
show ap arm client-match restriction-table	Displays additional statistics for the Client Match feature.

Command History

Release	Description
ArubaOS 8.7.0.0	The output of the command was modified to also display 6 GHz capable.
ArubaOS 8.7.0.0	The output of the command was modified to also display IPv6 address of the AP.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap vlan-mcast

```
show ap vlan-mcast [{ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}]
```

Description

This command shows the user count in each VLAN and timestamps for tunnel to join or leave vlan-mcast group.

Parameter	Description
ap-name <ap-name>	Show user count VLAN data for a specific AP name.
bssid <bssid>	Show user count VLAN data for a specific MAC address.
ip-addr <ip-addr>	Show user count VLAN data for a specific IP address.
ip6-addr <ip6-addr>	Show user count VLAN data for a specific IPv6 address.

Example

Use the following command to show the user count in each VLAN:

```
(host)[mynode] #show ap vlan-mcast
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap usb-acl-prof

```
show ap usb-acl-prof {default}{profile-name}
```

Description

This command shows the AP USB profile.

Parameter	Description
default	Shows the default AP USB ACL profile.
<profile-name>	Shows the AP USB profile.

Examples

The following command shows the list of USB ACL profiles:

```
(host) [mynode] #show ap usb-acl-prof

AP USB ACL profile List
-----
Name           References  Profile Status
----           -
sample         1
default        0

Total: 2
The following command shows the details of an USB ACL profile:
(host) (mynode) #show ap usb-acl-prof default

AP USB ACL profile "default"
-----
Parameter      Value
-----
AP USB ACL Config  N/A
```

Related Commands

Command	Description
ap usb-acl-prof	Configures AP USB ACL profile.

show ap usb-device-mgmt

```
show ap usb-device-mgmt all|{ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}|{wired mac <wired mac>}
```

Description

This command shows the USB devices managed on an AP.

Parameter	Description
all	Show all managed USB devices.
ap-name <ap-name>	Show USB devices managed on an AP that is specified by the AP name.
ip-addr <ip-addr>	Show USB devices managed on an AP that is specified by the IP address.
ip6-addr <ip6-addr>	Show USB devices managed on an AP that is specified by the IPv6 address.
wired mac <wired mac>	Show USB devices managed on an AP that is specified by the MAC address.

Example

The following command shows the list of all managed USB devices:

```
(host) [mynode] #show ap usb-device-mgmt all

USB Device
-----
Device ID  AP mac  Vender ID  Product ID  Manufacturer  Product  Version
Serial Number  Class  Device  Driver  Uptime
-----  -----  -----  -----  -----  -----  -----
-----  -----  -----  -----  -----  -----  -----
```

Related Commands

show ap usb verbose

```
show ap usb verbose {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command shows the details of Aruba USB modem.

Parameter	Description
ap-name <name>	Shows data for an AP with a specific name.
ip-addr <ipaddr>	Shows data for an AP with a specific IPv4 address.
ip6-addr <ip6-addr>	Shows data for an AP with a specific IPv6 address.

Example

The following command shows the details of an AP USB profile.

```
(host) [mynode] (config) #show ap usb verbose ap-name 20:4c:03:a4:a6:85

Command History

Release	Modification
ArubaOS 8.10.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Enable Mode.

show ap vlan-usage

```
show ap vlan-usage [{ap-name <ap-name> | bssid <bssid> | essid <ssid> | ip-addr <ip-addr> | ip6-addr <ip6-addr> | virtual-ap <virtual-ap>}
```

Description

Shows the number of clients on each VLAN.

Parameter	Description
ap-name <ap-name>	Show VLAN data for an AP with a specific name.
bssid <bssid>	Show VLAN data for a specific Basic Service Set Identifier (BSSID) on an AP. The Basic Service Set Identifier (BSSID) is usually the MAC address of the AP.
ssid <ssid>	Show VLAN data for a specific Extended Service Set Identifier (ESSID). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks.
ip-addr <ip-addr>	Show VLAN data for an AP with a specific IP address by entering an IP address in dotted-decimal format.
ip6-addr <ip6-addr>	Show VLAN data for an AP with a specific IPv6 address by entering an IP address in dotted-decimal format.
virtual-ap <virtual-ap>	Show VLAN pool allocation by VAP name.

Examples

The output of this command displays the **VLAN Usage** table :

```
(host) [mynode] #show ap vlan-usage
VLAN Usage Table
-----
VLAN ID  Clients
-----  -
64       1
65       32
66       44
```

The output of this command includes the following information:

Output	Description
VLAN ID	ID number of the wireless VLAN.
Clients	Number of clients currently using the specified VLAN.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on the managed device or controller where the AP terminates.

show ap wifi-uplink blacklist/ show ap wifi-uplink denylist

```
show ap wifi-uplink blacklist / show ap wifi-uplink denylist {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
```

Description

Shows a list of Wi-Fi uplink APs that have been denied access. The optional output modifiers | begin | exclude | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Name of the AP that has been blocked.
bssid <bssid>	Name of the required BSSID of the AP.
ip-addr <ip-addr>	IP address of the blocked AP.

Example

The following example displays the output of the blacklist/denylist command:

```
(host) [md] #show ap wifi-uplink blacklist/show ap wifi-uplink denylist ip-addr 10.65.43.247
WiFi uplink candidates
-----
essid bssid channel rssi encryption phy block-time remaining-time

show ap wifi-uplink candidates

```
show ap wifi-uplink candidates {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
```

Description

Shows a list of Wi-Fi uplink candidate APs. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Name of the candidate AP for Wi-Fi client. Default: AP name.
bssid <bssid>	Name of the required BSSID of the AP.
ip-addr <ip-addr>	IP address of the candidate AP for Wi-Fi client.

Example

The following example displays the output of an uplink candidate. (For versions prior to ArubaOS 8.10.0.0)

```
(host) [mynode] #show ap wifi-uplink candidates ip-addr 10.65.43.247
WiFi uplink candidates

Total candidates:2; Current time: 2021-07-14 05:05:27

```

The output of this command includes the following information:

Output	Description
ssid	Name of the required ESSID to which the client is associated.
bssid	Name of the required BSSID to which the client is associated.
channel	The radio channel used by the AP.
band	The radio band used by the AP.
rsssi	The Received Signal Strength Indicator (RSSI) of the AP radio.
encryption	The encryption type used on the AP.
phy	The AP association for the specified PHY radio type (2.4 GHz, 5 GHz, or 6 GHz).
rank	The rank details of the AP.
up time	Number of hours, minutes and seconds since the discovered AP starts the BSS service or advertises the beacon, in the format hours:minutes:seconds.
last update (total updates)	Date and time stamp of the last AP update.

show ap wifi-uplink connection-history

```
show ap wifi-uplink connection-history {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
```

Description

Shows the connection history of APs with Wi-Fi uplink. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ap-name <ap-name>	Name of the AP with Wi-Fi client.
bssid <bssid>	Name of the required BSSID of the AP.
ip-addr <ip-addr>	IP address of the AP with Wi-Fi client.

Example

The following example shows the output of a connection history of a Wi-Fi uplink AP. (For versions prior to ArubaOS 8.10.0.0.)

```
(host) [mynode] #show ap wifi-uplink connection-history ip-addr 10.65.43.247
WiFi uplink connection history
-----
timestamp          essid          bssid          channel  rssi  result
-----
2019-02-27 19:37:41 gran-uplink    ac:a3:1e:d2:19:d0 36      51    SUCCESS
2019-02-28 05:01:12 gran-uplink    ac:a3:1e:d2:19:d0 149     52    SUCCESS
Total connection times:2; Current time: 2019-02-28 12:51:35
```

The following example shows the output of a connection history of AP-655 access point with Wi-Fi uplink enabled (ArubaOS 8.10.0.0 or later versions).

```
(host) [mynode] #show ap wifi-uplink connection-history ap-name ap655-8391
WiFi uplink connection history
-----
timestamp          essid          bssid          channel  band  rssi
result
-----
-----
2021-07-14 04:48:59 test-wifi-wpa3 1c:28:af:68:2a:70 37      6GHz  178
SUCCESS
Total connection times:1; Current time: 2021-07-14 05:03:15
```

The output of this command includes the following information:

Output	Description
timestamp	The date and time when the entry was created.
ssid	Name of the required ESSID to which the client is associated.
bssid	Name of the required BSSID to which the client is associated.
channel	The radio channel used by the AP.
band	The radio band used by the AP.
rssi	The Received Signal Strength Indicator (RSSI) of the AP radio.
result	The success or failure status of the connection.

```

The output of this command includes the following information:

Output	Description
ESSID	Name of this instance of the profile.
BSSID	Name of the required BSSID to which the client is associated.
Allowed band	The radio band(s) on which the Wi-Fi uplink is used: <ul style="list-style-type: none"> ▪ a: 802.11a band only (5 GHz) ▪ g: 802.11g band only (2.4 GHz) ▪ all: Both 802.11a and 802.11g bands (5 GHz and 2.4 GHz)
Encryption	Name of the required BSSID to which the client is associated.
WEP Key 1	The first static WEP key associated with the key index. Can be 10 or 26 hex characters in length.
WEP Key 2	The second static WEP key associated with the key index. Can be 10 or 26 hex characters in length.
WEP Key 3	The third static WEP key associated with the key index. Can be 10 or 26 hex characters in length.
WEP Key 4	The fourth static WEP key associated with the key index. Can be 10 or 26 hex characters in length.
WEP Transmit Key Index	The key index to specify which static WEP key is to be used. Can be 1, 2, 3, or 4.
WPA Hexkey	The WPA Pre-Shared Key (PSK).
WPA Passphrase	The WPA password that generates the PSK.

show ap wifi-uplink debug

```
show ap wifi-uplink debug
  mat-table {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
  supplicant-log {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
  wcd-debug-log {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
  wcd-error-log {ap-name <ap-name> | bssid <bssid> | ip-addr <ip-addr>}
```

Description

Show debug information of APs with Wi-Fi uplink. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
mat-table	MAC address translation table of Wi-Fi uplink. This parameter has the following sub-parameters: <ul style="list-style-type: none">▪ ap-name <ap-name> Name of the AP with Wi-Fi client.▪ bssid <bssid> Name of the required BSSID of the AP.▪ ip-addr <ip-addr> IP address of the AP with Wi-Fi client.
supplicant-log	Supplicant log information. This parameter has the following sub-parameters: <ul style="list-style-type: none">▪ ap-name <ap-name> Name of the AP with Wi-Fi client.▪ bssid <bssid> Name of the required BSSID of the AP.▪ ip-addr <ip-addr> IP address of the AP with Wi-Fi client.
wcd-debug-log	Debug log information of wcd process. This parameter has the following sub-parameters: <ul style="list-style-type: none">▪ ap-name <ap-name> Name of the AP with Wi-Fi client.▪ bssid <bssid> Name of the required BSSID of the AP.▪ ip-addr <ip-addr> IP address of the AP with Wi-Fi client.
wcd-error-log	Error log information of wcd process. This parameter has the following sub-parameters: <ul style="list-style-type: none">▪ ap-name <ap-name> Name of the AP with Wi-Fi client.▪ bssid <bssid> Name of the required BSSID of the AP.▪ ip-addr <ip-addr> IP address of the AP with Wi-Fi client.

Example

The following command displays the debug log of wcd process for an AP with Wi-Fi uplink:

```
(host) [mynode] #show ap wifi-uplink debug wcd-error-log ip-addr 10.65.45.61

```

The output of this command includes the following information:

Output	Description
essid	Name of the required ESSID to which the client is associated.
bssid	Name of the required BSSID to which the client is associated.
channel	The radio channel used by the AP.
band	The radio band used by the AP.
rssi	The Received Signal Strength Indicator (RSSI) of the AP radio.
encryption	The encryption type used on the AP.
phy	The AP association for the specified PHY radio type (802.11a or 802.11g)
up-time	Number of hours, minutes and seconds since the discovered AP starts the BSS service or advertises the beacon, in the format hours:minutes:seconds.
last update (total updates)	Date and time stamp of the last AP update.

show ap wired-ap-profile

```
show ap wired-ap-profile [<profile-name>]
```

Description

Shows a list of all wired AP profiles, or displays the configuration parameters in a specific wired AP profile. If you include the optional `<profile-name>` parameter, the command will display detailed information for that one profile.

Parameter	Description
<code><profile-name></code>	Name of a wired AP profile.

Example

The output of this command shows the configuration parameters for the wired AP profile "default":

```
(host) [mynode] #show ap wired-ap-profile default
Wired AP profile "default"
-----
Parameter                               Value
-----
Wired AP enable                           Disabled
Trusted                                   not trusted
Forward mode                              tunnel
Switchport mode                          access
Access mode VLAN                          1
Trunk mode native VLAN                    1
Trunk mode allowed VLANs                  1-4094
Broadcast                                  Broadcast
```

The output of this command includes the following information:

Output	Description
Wired AP enable	Indicates whether the wired AP profile is enabled or disabled .
Forward mode	The configured forward mode for the profile: <ul style="list-style-type: none">▪ bridge: Bridge locally▪ split-tunnel: Tunnel to controller or NAT locally▪ tunnel: Tunnel to controller
Switchport mode	The profile's switching mode.

Output	Description
	<ul style="list-style-type: none"> ▪ access: Set access mode characteristics of the interface. ▪ mode: Set trunking mode of the interface. ▪ trunk: Set trunk mode characteristics of the interface.
Access mode VLAN	VLAN ID of the access mode VLAN.
Trunk mode native VLAN	VLAN ID of the native VLAN.
Trunk mode allowed VLANs	Range of allowed VLAN IDs for the native VLAN.
Trusted	Shows if the wired port on an AP using this profile is a trusted port. Possible values are Trusted or Not Trusted .
Broadcast	If set to broadcast , the wired AP port will forward broadcast traffic. If the parameter displays Do Not Broadcast , broadcast traffic will not be forwarded.

Related Commands

show ap wired-port-profile

```
show ap wired-port-profile [<profile-name>]
```

Description

Shows all AP wired port profiles and their status.

Parameter	Description	Default
<profile-name>	Name of a wired AP profile.	default

Example

The following example shows that the controller has three wired port profiles. The **References** column lists the number of other profiles with references to the wired port profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) [mynode] #show ap wired-port-profile

AP wired port profile List
-----
Name                References  Profile Status
----                -
default             3
NoAuthWiredPort    4          Predefined (editable)
shutdown            3          Predefined
Total:3
```

The following command displays information for an individual wired port profile:

```
(host) [mynode] #show ap wired-port-profile default

AP wired port profile "default"
-----
Parameter                Value
-----
Wired AP profile          default
Ethernet interface link profile default
AP LLDP profile           default
Shut down                 No
Remote-AP Backup          Enabled
AAA Profile                N/A
Time to wait for authentication to succeed 20 sec
Loop Protect Enable       Disabled
Loop Detection Interval   1
Loop Protect Auto Recovery Enable Disabled
```

Loop Protect Auto Recovery Interval	300
Storm Control Broadcast	Disabled
Storm Control Broadcast Threshold	2000

The output of this command includes the following information:

Parameter	Description
Wired AP profile	Name of a wired AP profile to be used by devices connecting the AP's wired port. The wired AP profile defines the forwarding mode and switchport values used by the port.
Ethernet interface link profile	An Ethernet Link profile to be used by devices connecting to the AP's wired port profile. This profile defines the duplex value and speed to be used by the port.
AP LLDP Profile	Name of an LLDP Profile associated with this wired port.
Shut Down?	Shows if the wired AP port is enabled (no) or disabled (yes).
Remote AP Backup	Use the rap-backup parameter to use the wired port on a Remote AP for local connectivity and troubleshooting when the AP cannot reach the controller. If the AP is not connected to the controller, no firewall policies will be applied when this option is enabled. (The AAA profile will be applied when the AP is connected to controller).
AAA Profile	Name of an AAA profile to be used by devices connecting to the wired port of the AP.
Time to wait for authentication to succeed	Authentication timeout value, in seconds, for devices connecting the AP's wired port. The supported range is 1-65535 seconds, and the default value is 20 seconds.
Loop Protect Enable	Shows if loop protection is enabled or disabled.
Loop Detection Interval	Shows time in seconds after which a loop detection packet is transmitted on the AP port.
Loop Protect Auto Recovery Enable	Show if automatic recovery of the port in the AP that is shut down because of loop protection is enabled or disabled.
Loop Protect Auto Recovery Interval	Shows time in seconds after which automatic recovery of the port in the AP that is shut down because of loop protection is attempted.

Parameter	Description
Storm Control Broadcast	Shows if broadcast storm control is enabled or disabled.
Storm Control Broadcast Threshold	Shows broadcast packets per second on each Ethernet port of an AP before the Ethernet port is shut down.

show ap wired stats

```
show ap wired stats {ap-name <ap-name> | ip-addr <ip-addr>} [client-ip <client-ip> | client-mac <client-mac>]
```

Description

This command shows statistics for campus and remote AP wired clients.

Parameter	Description
ap-name <ap-name>	Show wired AP statistics for a specified AP name.
ip-addr <ip-addr>	Show wired AP statistics for a specified AP by entering an IP address in dotted-decimal format.
client-ip <client-ip>	Show wired AP statistics for a specified client IP address.
client-mac <client-mac>	Show wired AP statistics for a specified client MAC address.

Example

```
(host) [mynode] # show ap wired stats ap-name rap5wn client-mac 00:14:d1:19:3c:0b
AP Wired User Statistics
-----
Counter          Value
-----

show ap wmm-flow

```
show ap wmm-flow [ap-name <ap-name> | bssid <bssid> | dot11a | dot11g | 2.4GHZ | 5GHZ | 6GHz | essid <essid> | ip-addr <ip-addr> | ip6-addr <ip6-addr>]
```

Description

This command shows the Wireless Multimedia (WMM) flow table.

WMM, or Wireless Multimedia Extensions, are a subset of the 802.11e standard. WMM provides for four different types of traffic classification: voice, video, best effort, and background, with voice having the highest priority and background the lowest. Issue the `show ap wmm-flow` command to view WMM flow data for all APs. Include any of the optional parameters described in the table above to filter the table by a specific AP, radio channel (a or g), or both AP and radio type.

Parameter	Description
<code>ap-name <ap-name></code>	View an AP with a specified name.
<code>bssid <bssid></code>	View data for an AP with a specific BSSID (Basic Service Set Identifier). The Basic Service Set Identifier (BSSID) is usually the MAC address of the AP.
<code>dot11a</code> (For versions prior to ArubaOS 8.9.0.0)	Show the WMM flow table for a 802.11a radio.
<code>dot11g</code> (For versions prior to ArubaOS 8.9.0.0)	Show the WMM flow table for a 802.11g radio.
<code>2.4GHz</code> (ArubaOS 8.9.0.0 or later versions)	Show the WMM flow table for a 2.4 GHz radio.
<code>5GHz</code> (ArubaOS 8.9.0.0 or later versions)	Show the WMM flow table for a 5 GHz radio.
<code>6GHz</code> (ArubaOS 8.9.0.0 or later versions)	Show the WMM flow table for a 6 GHz radio.
<code>essid <essid></code>	View data for a specific ESSID (Extended Service Set Identifier). An Extended Service Set Identifier (ESSID) is a alphanumeric name that uniquely identifies a wireless network. If the name includes spaces, you must enclose the ESSID in quotation marks.
<code>ip-addr <ip-addr></code>	View an AP with a specified IP address by entering an IP address in dotted-decimal format.

Parameter	Description
ip6-addr <ip6-addr>	View an AP with a specified IPv6 address by entering an IPv6 address in dotted-decimal format.

Example

Some examples of executing this command with various options are as follows:

```
(host) [mynode] #show ap wmm-flow ap-name ap105
(host) [mynode] #show ap wmm-flow ap-name ap105 dot11g
(host) [mynode] #show ap wmm-flow dot11a
The following example shows WMM flow data for all APs:
(host) [mynode] #show ap wmm-flow

WMM Flow Table
-----
AP Name      ESSID  Client          Description
-----
AP125-srk   NOE    00:90:7a:06:1f:5b  tsid 6:prio 6:inactivity 2157352960
us:bidir:apsd:normalack:tclas prio 6 ip DIP-192.168.101.194 DP-32514 DSCP-

us:bidir:apsd:normalack:no-match
Num Flows:0
```

The output of this command includes the following parameters:

Parameter	Description
AP name	Name of an AP with recorded WMM flows.
ESSID	Extended Service Set Identifier (ESSID) of a wireless network.
Client	MAC address of the client.
Description	<p>The description is a long string that includes the following information:</p> <p>TSID: Traffic Stream Identifier. The TSID should match the priority level for each flow.</p> <p>Priority: One of the following IEEE 802.1p priority values:</p> <ul style="list-style-type: none"> ■ 0,3 = Best Effort ■ 1,2 = Background ■ 4-5 = Video ■ 6-7 = Voice <p>Inactivity: Tspec inactivity threshold, in microseconds.</p> <p><country code>: AP country code, e.g., US.</p> <p>bidir: flow is bidirectional.</p> <p>apsd: flow has enabled auto power save delivery.</p>

Parameter	Description
	<p><ack>: Displays the ack policy negotiated for the flow. Possible values are:</p> <ul style="list-style-type: none"> ■ normalack ■ noack ■ blockack ■ resack (reserved ack) <p>Tclas: traffic classification element. Tclas information includes one of the following classification types, the 802.1p priority and IP version (version 4 or version 6)</p> <ul style="list-style-type: none"> ■ type0: Classification based on Ethernet parameters ■ type1: Classification based on TCP/UDP or IP parameters (IPv4 or IPv6) ■ type2: Classification based on based on IEEE802.1Q <p>DIP: Destination IP address for the flow.</p> <p>DP: Destination IP Port specified in the TCLAS for flow negotiation.</p> <p>DCSP: The Differentiated Services Code Point (DSCP) priority value that matches the flows 802.1p priority.</p>

show ap-crash-transfer

```
show ap-crash-transfer
```

Description

This command displays info for the AP crash transfer feature, which transfers AP coredump files to the controller flash memory if no dumpserver is configured.

The command `ap system-profile <profile> dump-server <server>` specifies a server to receive a core dump generated when an AP process crashes. If no dump server is configured, issue the `ap-crash-transfer` command to save dump files to the controller flash memory.

If you define a dump server and issue the `ap-crash-server` command, the dump server configuration takes precedence, and coredump files are sent to the dump server.

Example

```
(host)[mynode] #show ap-crash-transfer
AP Crash Transfer:enabled
AP Crash folder limit:50 MB (non-editable)
```

Related Commands

Command	Description
<code>ap-crash-transfer</code>	This command allows AP coredump files to be transferred to the controller flash memory if no dumpserver is configured.

show arp

```
show arp
  counters
  vlan <vlanid>
```

Description

This command shows Address Resolution Protocol (ARP) entries for the controller.

Parameter	Description
counters	Shows ARP information on ARP counters.
vlan <vlanid>	Shows ARP information for a VLAN Interface Number. 1–4094

Example

```
This example shows configured static ARP entries for the controller.
(host) [mynode] #show arp
Protocol      Address      Hardware Address      Interface
Internet     10.3.129.98  00:1A:1E:C0:80:28    vlan1
Internet     10.3.129.253 00:0B:86:42:35:80    vlan1
Internet     10.3.129.250 00:1A:92:45:DB:00    vlan1
Internet     10.3.129.99  00:1A:1E:C0:1C:60    vlan65
Internet     10.3.129.96  00:1A:1E:C0:80:1E    vlan65
Internet     10.3.129.254 00:0B:86:02:EE:00    vlan1
```

The output of this command includes the following parameters:

Parameter	Description
Protocol	Protocol using ARP. Although the controller will most often use ARP to translate IP addresses to Ethernet MAC addresses, ARP may also be used for other protocols, such as Token Ring, FDDI, or IEEE 802.11, and for IP over ATM.
Address	IP address of the device.
Hardware Address	MAC address of the device.
Interface	Interface used to send ARP requests and replies.

Related Commands

show audit-trail

```
show audit-trail [history | login <number>| <number>]
```

Description

Shows the controller's audit trail log.

Parameter	Description
history	Shows audit trail history log.
login <number>	Starts displaying the log output from the specified number of lines from the end of the login or logout log. 1-65535
<number>	Starts displaying the log output from the specified number of lines from the end of the log. 1-65535

Example

By default, the audit trail feature is enabled for all commands in configuration mode. The example below shows the most recent ten audit log entries for the managed device.

```
(host) [mynode] #show audit-trail 10
Feb  5 06:13:17 cli[1239]: USER: admin has logged in from 10.240.16.118.

show auth-tracebuf

```
show auth-tracebuf [count <1-250> | [failures] | mac <address>]
```

Description

This command shows the trace buffer for authentication events. Use the output of this command to troubleshoot 802.1X authentication errors. Include the <address> parameter to filter data by the MAC address of the client which is experiencing errors.

Parameter	Description
count <number>	Limits the output of the command to the specified number of packets. 1-250
failures	Filters the output of this command to display only authentication failures
mac <address>	Filters the output of this command to display only information for a specified MAC address.

Example

The example below shows the most recent ten trace buffer entries for the controller. Each row includes the following information:

```
(host) [mynode] # show auth-tracebuf count 10

```

Each row in the output of this table may include some or all of the following information:

- A timestamp that indicates when the entry was created
- The type of exchange that was made
- The direction the packet was sent
- The source MAC address
- The destination MAC address
- BSSID/Server Name
- The packet number
- The packet length
- Additional information (if available); for example, username, encryption and WPA type, or reason for failure

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show banner

```
show banner
show bannervia
```

Description

This command shows the current login banner. Use this command to review the banner message that appears when you first log in to the controller's command-line or browser interfaces.

Parameter	Description
banner	Displays the Message of the Day banner.
bannervia	Displays the VIA login banner message.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

```
(host) [mynode]# show banner
This testlab controller is scheduled for maintenance starting Saturday night at
11 p.m.
```

  azure-iothub-log
  disp-attr
  iot-profile
  iotRequests
  jobs
  papi-stats
  report
  tag-report
  transport_context
  ws-log
```

Description

This command displays all the values configured for Bluetooth Low Energy (BLE) relay on devices.

Parameter	Description
apbinfo_ack_state	Display APB acknowledgment information.
azure-iothub-log	Display Azure IoT Hub connection logs.
disp-attr	Display value of attribute
iot-profile	Display recent iot profile and transport context
iotRequests	Show JSON blobs received thru REST API calls as part of IoT gateway functionality
jobs	Show ble relay job queue status
papi-stats	Display PAPI stats for ble_relay.
report	Show logs for most recent beacon update
tag-report	Display recent tag data sent via websocket
transport_context	Display transport context information.
ws-log	Show web socket connection logs

show ble service-profile

show ble service-profile <profile-name>

Description

This command displays the Bluetooth Low Energy (BLE) service profiles.

Parameter	Description
<profile-name>	Displays the BLE service profile specified by the name.

Example

The following command exports the AP's BLE iBeacon information into a CSV file:

```
(host) [mynode] #show ble service-profile default

Ble Service Profile "default"
-----
Parameter          Value
-----
Advertisement Format  ibeacon
Radio Instance      all
Include Ap Group    lobby
Major Range         0-65535
Minor Range         0-65535
uuid                4152554E-F99B-4A3B-86D0-947070693A78
```

show bocmgr

```
show bocmgr instance
  instance {device <device-id>}{interface tunnel|vlan {intf-id
<intfid>}|<nodepath>} {pool dhcp|tunnel|vlan {pool-name <pool-name>}|<nodepath>}
  pool {dhcp|intf|tunnel|vlan {pool-name <pool-name>}|<nodepath>}|{intf tunnel|vlan
{intf-id <intfid>}|<nodepath>}
```

Description

This command shows details about dynamic VLAN, tunnel, and DHCP pools.

Parameter	Description
device <device-id>	Show pools information for a device with the specified MAC address (device ID).
interface tunnel vlan	Show pool information for a specific tunnel or vlan
intf-id <intfid>	Show pool information for the specified tunnel or interface ID
<nodepath>	Show pool information for a configuration node at the specified path. (For example, /md/west/sunnyvale.)
pool dhcp tunnel vlan	Show pool information for the specified pool type.
pool-name <pool-name>	Show a list of devices using the specified pool.
<nodepath>	Show pool information for a configuration node at the specified path. (For example, /md/west/sunnyvale.)
pool dhcp {[intf]tunnel vlan}	Show pool information for the specified interface or pool type.
pool-name <pool-name>	Show details about a pool with the specified pool name
intf-id <intfid>	Display pool details info for the specified tunnel or interface ID
<nodepath>	Display pool details info for a configuration node at the specified path. (For example, /md/west/sunnyvale.)

Example

The following command shows the DHCP pool used by the configuration /md/east.

```
(host) [md])#show bocmgr instance pool dhcp /md/east
DHCP Instance(s)
-----
```

Device Name	Pool Name	Net	Mask	Vlan Id	Vlan IP
00:0b:86:99:88:17	testpool	4.1.0.0	255.255.255.192	2	4.1.0.1
00:0c:29:0e:56:65	testpool	4.1.0.64	255.255.255.192	2	4.1.0.65

show bulkedit

```
show bulkedit {headers | status}
```

Description

This command shows the bulkedit information such as the list of supported bulkedit headers or the status of the last bulkedit transaction.

Parameter	Description
headers	Show list of supported bulkedit headers.
status	Show status of last bulkedit transaction.

Example

The following are examples of executing the `show bulkedit` command:

```
(host) [mynode] #show bulkedit headers
(host) [mynode] #show bulkedit status
```

Related Commands

Command	Description

show ca-bundle version

```
show ca-bundle version
```

Description

This command displays the version number of CA certificates.

Example

The following command displays the version number of CA certificates:

```
(host) [mynode] #show ca-bundle version
Active CA Bundle version: 1
```

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on managed devices.

show ccm-debug memory-usage

```
show ccm-debug memory-usage {non-profile | profile}
```

Description

This command shows the memory usage information.

Parameter	Description
non-profile	Shows memory usage - non-profile command.
profile	Shows memory usage - profile command.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following is an example for executing this command:

```
(host) [mynode] #show ccm-debug memory-usage non-profile  
  
NON-PROFILE Memory Usage Summary:  
  
Memory used for commandobj storage:: 6562  
Memory used by buffer management:: 0  
Memory Usage Total:: 6562

show clock

```
show clock [cli-timestamp|timezone]
```

Description

This command shows the configuration for the system clock, summer daylight savings configuration, timezone configuration, and gives details if the CLI-timestamp is enabled or disabled. Include the optional summer-time parameter to display configured daylight savings time settings. The timezone parameter shows the current timezone, with its time offset from Greenwich Mean Time.

Parameter	Description
cli-timestamp	Shows if clock cli-timestamp is enabled or disabled.
summer-time	Shows summer (daylight savings) time settings.
timezone	Show the configured timezone for the managed device.

Example

The output below shows the current zone time on the managed device clock.

```
(host) [mynode] #show clock timezone
clock timezone PST -8
```

Related Commands

Command	Description
clock summer-time recurring	Configures daylight savings /summer time settings

show cluster-config

show cluster-config

Description

This command show the cluster configuration for the control plane security feature.

When you issue this command from the cluster *root*, the output of this command shows the cluster role of the managed device, and the IP address of each member node in the cluster.

When you issue this command from a cluster *member*, the output of this command shows the cluster role of the managed device, and the IP address of the cluster root.

Example

In the example below, the **Cluster Role** section in the output of this command shows that the managed device on which the command was issued is the cluster root. The **Cluster IPSEC controllers** section of the output shows the IP address of each cluster member.

```
(host) [mynode] (config) #show cluster-config

Cluster Role
-----
Root
----

Cluster IPSEC controllers
-----
Switch IP address of Cluster-Members  Key
-----
172.21.18.18      *****
172.21.18.19      *****
```

Related Commands

Command	Description
control-plane-security	Configures the control plane security profile.
cluster-member-ip	Sets the controller as a control plane security cluster root, and specifies the IPsec key for a cluster member.
cluster-root-ip	Sets the controller as a control plane security cluster member, and defines the IPsec key for communication between the cluster member and the controller's cluster root.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on cluster member or cluster root controllers.

show cluster-switches

show cluster-switches

Description

Execute this command on a Mobility Conductor using control plane security in a multi-master/ conductor environment to show other managed devices to which it is connected.

When you issue this command from the cluster root, the output of this command displays the IP address of the VLAN used by the cluster member to connect to the cluster root.

When you issue this command from a cluster member, the output of this command displays the IP address of the VLAN used by the cluster root to connect to the cluster member.

Example

In the example below, the `show cluster-switches` command was issued on a cluster member. The **Switch-IP** section of the output shows the IP address of a VLAN on cluster root, indicating that the cluster member can currently communicate with the cluster root. If the managed device cannot communicate with the cluster root, this table will be blank.

```
(host) [mynode] (config) #show cluster-switches

SWITCH-IP          CLUSTER-ROLE
-----
172.21.18.18      ROOT
```

In this example, the `show cluster-switches` command was issued on a cluster root. The **Switch-IP** section of the output shows the IP address of a VLAN on each cluster member that can currently communicate with the cluster root.

```
(host) [mynode] (config) #show cluster-switches

SWITCH-IP          CLUSTER-ROLE
-----
172.21.18.18      MEMBER
172.21.18.19      MEMBER
```

Related Commands

Command	Description

show cluster-tech-support

show cluster-tech-support <filename>

Description

Displays cluster-related information in relation to the managed device.

Parameter	Description
<filename>	Specifies the file name where the command output will be stored. Maximum length of filename is 127 characters.

Example

The following command is used to store the logged cluster data:

```
show cluster-tech-support <filename>
```

Related Commands

show command-details

show command-details <COMMAND>

Description

This command displays the command debugging details for a command executed in the CLI session.

Parameter	Description
<COMMAND>	Enter the command that is executed in the CLI session and for which you need the command details. The command text must be within quotation marks

Example

The following example shows the output for this command.

```
(host) [mynode] #show command-details "show cellular profile"
Command Details:
-----
APP Name: Layer2/3 , Object:5126 , OperationType: Async
Objname/Container: /CHK_PARENT, MajorVer: 8 , MinorVer: 1 , Instance: NULL
Local Command: 0 , Remote Command: 0 , Remote IpAddr: NULL
Current config Node: /mm/mynode
Command Key Values:
-----
Key          Value      Instance Key
---          -
CELLULAR    CELLULAR   FALSE
PROFILE     PROFILE    FALSE
```

show configuration

```
show configuration [committed <node-path> | counters platform-capability |  
datastore {[committed | default | detail | inherited | json | local | node-  
hierarchy | non-default | object | pending | stats | system | user]} | devices |  
diff | effective | failure | filtered | node-hierarchy | partial | pending |  
profile-committed | received | setup-dialog <macaddr> | similar | state | system-  
commands | unsaved-nodes]
```

Description

This command shows the saved configuration on the controller. Execute this command to view the entire configuration saved on the controller, including all profiles, ACLs, and interface settings.

Parameter	Description
committed [<node-path>]	Shows committed configuration of the configuration node.
counters platform-capability	Shows internal counters at the node and platform capability-based information.
datastore [committed default detail inherited json local node-hierarchy non-default object <objname> [detail json <node-path>] pending stats system user] [<node-path>]	Shows datastore configuration.
devices [debug <node-path>]	Shows devices list and nodes mapped to it.
diff <conf1> <conf2> [context json]	Shows the difference between two configuration items. New commands are prefixed with a plus, deleted commands are prefixed with a minus.
effective [detail <node-path>]	Shows effective configuration of devices connected to the node.
failure [all migration {[config-node device]} replace-config <A.B.C.D>]	Shows the configuration errors.

Parameter	Description
filtered	Show configuration downgraded to other versions.
node-hierarchy [debug]	Shows the configuration node hierarchy.
partial [<node-path>]	Shows incremental configuration changes between last two commits.
pending [<node-path>]	Shows pending configuration of the configuration node.
profile-committed [<node-path>]	Shows committed configuration of profiles at this node.
received	Shows the received configuration from Mobility Conductor.
setup-dialog <macaddr>	Shows the setup-dialog configuration of the device.
similar <conf1> conf2> [json]	Shows the common configuration between two configuration items.
state pending [<node-path>]	Shows the configuration state information.
system-commands {committed pending} [<node-path>]	Shows system or hidden commands at the configuration node.
unsaved-nodes	Shows the list of unsaved configuration nodes.

Example

The following example shows part of the output for this command.

```
(host) [mynode] #show configuration
version 8.0
country US
logging level warnings security subcat ids
logging level warnings security subcat ids-ap
wms
general poll-interval 60000
general poll-retries 3
```

```

general stat-update enable
general ap-ageout-interval 30
general sta-ageout-interval 30
general learn-ap disable
general persistent-known-interfering enable
!
adp discovery
adp igmp-join
adp igmp-vlan 0
.

show controller-ip

show controller-ip

Description

Shows the IPv4 address and VLAN interface ID of the controller.

Example

The output of this command shows the IP address and VLAN interface ID.

```
(host) # show controller-ip

Switch IPv4 Address: 10.17.24.19
Switch IPv4 is configured to be Vlan Interface: 1501
Switch IPv6 Address: 2001::1
Switch IPv6 address is configured to be Vlan Interface: 1501
```

Related Commands

Command	Description
controller-ip	Sets the IP address of the to the loopback interface address or a specific VLAN interface address.

Command History

Release	Modification
ArubaOS 8.7.0.0	The output of the command was modified to display Switch IP as Switch IPv4 .
ArubaOS 8.0.0.0	Command introduced.

Command Information

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show control-plane-security

show control-plane-security

Description

Shows the current configuration of the control plane security profile. The control plane security profile enables and disables the control plane security feature and identifies campus APs to receive security certificates. Issue this command to view current control plane security settings.

Example

The following command shows whether the control plane security and auto certificate provisioning features are enabled in the control plane security profile, and the range of IP addresses that the controller will send certificates to.

```
(host)(config) #show control-plane-security
Control Plane Security Profile
-----
Parameter                               Value
-----
Control Plane Security                   Enabled
Auto Cert Provisioning                   Disabled
Auto Cert Allow All                      Enabled
Expiry timer(dd:hh)                     00:02
Auto Cert Allowed Addresses              N/A
Auto Cert Allowed IPv6 Addresses         N/A
```

Related Commands

Command	Description
control-plane-security	Configure the control plane security profile by identifying APs to receive security certificates.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show country

show country [trail]

Description

Shows the country and domain upgrade trail of the controller. A controller's country code sets the regulatory domain for the radio frequencies that the APs use. This value is typically set during the controller's initial setup procedure. Use this command to determine the country code specified during setup.

Parameter	Description
trail	Displays the record showing how the switch was reconfigured for its current country domain when the controller hardware was upgraded.

Example

The output of this command shows the controller's country, model, and hardware types.

```
(host) # show country
Country:US
Model:Aruba7240-US
Hardware:Restricted US
```

Command History

Release	Modification

show cp-bwcontracts

```
show cp-bwcontract
```

Description

Displays a list of Control Processor (CP) bandwidth contracts for whitelist/allowlist ACLs.

Example

The *CP bw contracts* table lists the contract names, the ID number assigned to each contract, and its defined traffic rate in packets per second.

```
(host) #show cp-bwcontracts

CP bw contracts
-----
Contract          Id      Rate (packets/second)
-----
cpbwc-ipv4        15785   2000
cpbwc-ipv6        15798   2000
cp-rate           15809    20
```

Related Commands

Command	Description
firewall cp	This command creates a new whitelist/allowlist ACL and can associate a bandwidth contract with that ACL.
cp-bandwidth-contract	This command configures a bandwidth contract traffic rate, which can then be associated with a whitelist/allowlist session ACL.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	PEFNG license.	Config or Enable mode on Mobility Conductor.

show cp-stats

show cp-stats

Description

This command shows the control plane (CP) queue statistics.

Example

Execute the following command to view the control plane queue statistics.

```
(host) [MDC] *#show cp-stats

high vc[1]: 0x000000000108a2e0 low vc[0] = 0x0000000024540fe8
rx_sequence: 0x0034c8ee tx_sequence = 0x0034c8ee
Total Packet count at ppp xmit 0
Total Packet drop at ppp xmit interface check 0
Total Packet drop at ppp xmit 0
Total Packet count at ppp tx fixup 0
Total Packet drop at ppp tx fixup 0

show cpuload

show cpuload [current | per-cpu]

Description

The `show cpuload` command displays the controller CPU load for application and system processes. The CPU load statistics for a controller can be viewed by using the `current` parameter, or displayed per-processor by using the `per-cpu` command.

Parameter	Description
current	Include this optional parameter at the request of Aruba technical support to display additional CPU troubleshooting statistics.
per-cpu	Displays the CPU load stats for a controller by individual processor.

Example

This example shows that the majority of the controller's CPU resources are not being used by either application (user) or system processes.

```
(host)[mynode] #show cpuload
user 6.9%, system 7.7%, idle 85.4%
```

The output of this command includes the following parameters:

Parameter	Description
user	Percentage of controller CPU resources used by application processes.
system	Percentage of controller CPU resources used by system processes.
idle	Percentage of unused controller CPU resources.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show crashinfo

show crashinfo

Description

This command shows the list of crashes in the system.

Example

The following is an example for executing this command:

```
(host) [mynode] #show crashinfo
Crash Info Table
-----
Crash Time           Process Name
-----
August 18 20:43      impystart
September 08 04:18   impystart
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show crypto-local ipsec-map

```
show crypto-local ipsec [tag <ipsec-map-name>]
```

Description

Displays the current IPsec map configuration on the controller. The command `show crypto-local ipsec` displays the current IPsec configuration on the controller.

Parameter	Description
tag <ipsec-map-name>	Display a specific IPsec map.

Examples

The command `show crypto-local ipsec-map` shows the default map configuration along with any specific IPsec map configurations.

```

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show crypto dp

```
show crypto dp [peer <source-ip>]
```

Descriptions

Displays crypto data packets. Use this command to send crypto data packet information to the controller log files, or to clear a crypto ISAKMP state associated with a specific IP address.

Parameter	Description
dp	Shows crypto latest datapath packets. The output is sent to crypto logs.
peer <source-ip>	Show crypto latest datapath packets for this peer—that is, shows crypto ISAKMP state for this IP.

Examples

The command `show crypto dp` sends debug information to CRYPTO logs.

```
(host) [mynode] #show crypto dp
Datapath debug output sent to CRYPTO logs.
```

Related Commands

show crypto dynamic-map

```
show crypto dynamic-map [tag <dynamic-map-name>]
```

Descriptions

This command displays IPsec dynamic map configurations. Dynamic maps enable IPsec SA negotiations from dynamically addressed IPsec peers. Once you have defined a dynamic map, you can associate that map with the default global map using the command [crypto map global-map](#).

Parameter	Description
dynamic-map	IPsec dynamic map configuration.
tag <dynamic-map-name>	A specific dynamic map.

Examples

The command show crypto dynamic-map shows IPsec dynamic map configuration.

```
(host) [mynode] #show crypto dynamic-map
Crypto Map Template"default-dynamicmap" 10000
IKE Version: 1
IKEv1 Policy: All
Security association lifetime seconds : [300 -86400]
Security association lifetime kilobytes: N/A
PFS (Y/N): N

show crypto ipsec

```
show crypto ipsec {ipsec-map-id | mtu | sa [peer v6 <peer-ipv6> | peer <peer-ip>] | transform-set [tag <transform-set-name>]}
```

Descriptions

Displays the current IPsec configuration on the managed device. Execute the `show crypto ipsec` command to view the Maximum Transmission Unit (MTU) size allowed for network transmissions using IPsec security. It also displays the transform sets that define a specific encryption and authentication type.

Parameter	Description
<code>ipsec-map-id</code>	Shows IPsec MAP to ID mapping.
<code>mtu</code>	Shows IPsec max mtu.
<code>sa</code>	Shows security associations (SAs).
<code>peer ip6 <peer-ipv6></code>	Shows IPsec SAs for an IPv6 peer.
<code>peer <peer-ip></code>	Shows IPsec SAs for this IP.
<code>transform-set</code>	Shows IPsec transform sets.
<code>tag <transform-set-name></code>	Shows a specific transform set.

Examples

The `show crypto ipsec transform-set` command displays the settings for both preconfigured and manually configured transform sets.

```
(host) [mynode] #show crypto ipsec transform-set
Transform set default-transform: { esp-3des esp-sha-hmac }
    will negotiate = { Transport, Tunnel }
Transform set default-ml-transform: { esp-3des esp-sha-hmac }
    will negotiate = { Transport, Tunnel }
Transform set default-boc-bm-transform: { esp-3des esp-sha-hmac }
    will negotiate = { Transport, Tunnel }
Transform set default-cluster-transform: { esp-aes256 esp-sha-hmac }
    will negotiate = { Transport, Tunnel }
Transform set default-1st-ikev2-transform: { esp-aes256 esp-sha-hmac }
    will negotiate = { Transport, Tunnel }
Transform set default-3rd-ikev2-transform: { esp-aes128 esp-sha-hmac }
    will negotiate = { Transport, Tunnel }
Transform set default-gcm256: { esp-aes256-gcm esp-null-hmac }
    will negotiate = { Transport, Tunnel }
```

```

Transform set default-gcm128: { esp-aes128-gcm esp-null-hmac }
    will negotiate = { Transport, Tunnel }

  udpencap-behind-natdevice
  uplink-vlan
  vlan
```

Descriptions

This command displays Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP). Use the show crypto isakmp command to view ISAKMP settings, statistics and policies.

Parameter	Description
block-aruba-ca	Shows the Configuration if Aruba-certified clients are blocked.
cluster IPAssignPendingRaps	Shows cluster configuration.
clusterIP	Show clusterIP hash table entries
clusterMAC	Show clusterMAC hash table entries
eap-passthrough	Displays configured IKEv2 EAP pass-through methods.
groupname	Shows the IKE Aggressive group name.
ike-mac-sa	Shows the MAC Hash table of IKE SA entries.
ipsecSPI	Shows IPsec SPI hash table entries.

Parameter	Description
key	Shows the IKE pre-shared keys.
lc-members	Shows cluster members.
log ap <macaddr>	Shows debugging log.
packet-dump	Shows the packet dump configuration.
policy <policy-number>	Shows the following information for predefined and manually configured IKE policies: <ul style="list-style-type: none"> ▪ IKE version ▪ encryption and hash algorithms ▪ authentication method ▪ PRF methods, ▪ DH group ▪ lifetime settings
sa	Shows the security associations.
[peer v6 <peer-ipv6> peer <peer-ip>]	Shows crypto ISAKMP security associations for this IP.
stats	Shows detailed IKE statistics. This information can be very useful for troubleshooting problems with ISAKMP.
timers	Shows IKEv1 timers.
transports	Shows IKE Transports.
udpencap-behind-natdevice	Shows the Configuration if NAT-T is enabled if managed device is behind a NAT device .
uplink-vlan	Shows the uplink vlan information .
vlan	Shows the Vlan state.

Examples

The **show crypto isakmp stats** command shows the IKE statistics.

```
(host) [mynode] #show crypto isakmp stats
Default protection suite 10001
Version 1
  encryption algorithm: 3DES - Triple Data Encryption Standard (168
bit keys)
  hash algorithm: Secure Hash Algorithm 160
  authentication method: Pre-Shared Key
```

```

Diffie-Hellman Group: #2 (1024 bit)
lifetime: [300 - 86400] seconds, no volume limit
Default RAP Certificate protection suite 10002
Version 1
encryption algorithm: AES - Advanced Encryption Standard (256 bit
keys)
hash algorithm: Secure Hash Algorithm 160
authentication method: Rivest-Shamir-Adelman Signature
Diffie-Hellman Group: #2 (1024 bit)
lifetime: [300 - 86400] seconds, no volume limit
Default RAP PSK protection suite 10003
Version 1
encryption algorithm: AES - Advanced Encryption Standard (256 bit
keys)
hash algorithm: Secure Hash Algorithm 160
authentication method: Pre-Shared Key
Diffie-Hellman Group: #2 (1024 bit)
lifetime: [300 - 86400] seconds, no volume limit

```

The **show crypto isakmp stats** command also displays the number of VIA VPN sessions initiated beyond the assigned limit:

```

(host) [mynode] (config) #show crypto isakmp stats | include max
VIA per user max session limit exceeded errors = 2

```

The **show crypto isakmp sa** command shows the IKE security associations.

```

(host) [mynode] #show crypto isakmp sa

show crypto-local isakmp

```
show crypto-local isakmp
  allow-via-subnet-routes
  ca-certificate
  certificate-group
  disable-aggressive-mode
  disable-ipcomp
  dpd
  key [peer <peer-ip> | fqdn <ike-id-fqdn>]
  max-allowed-ikev1-exchanges
  max-allowed-negotiations
  ppk
  server-certificate
  vpn-peer-passcode
  xauth
```

Descriptions

This command displays Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP). Use the **show crypto-local isakmp** command to view IKE parameters.

Parameter	Description
allow-via-subnet-routes	Shows if the Mobility Conductor is configured to accept subnet routes from VIA clients.
ca-certificate	Shows all the Certificate Authority (CA) certificates associated with VPN clients.
certificate-group	Shows the existing certificate groups by server certificate name and CA certificate.
disable-aggressive-mode	Shows if aggressive-mode is enabled or disabled.
disable-ipcomp	Shows IP compression configuration.
dpd	Shows the IKE Dead Peer Detection (DPD) configuration on the managed device.
key [fqdn <ike-id-fqdn> peer <peer-ip>]	Shows the IKE pre-shared key on the managed device for site-to-site VPN. This includes keys configured by Fully Qualified Domain Name (FQDN) and local and global keys configured by IP address.
max-allowed-ikev1-exchanges	Shows the maximum allowed ikev1-exchanges allowed at a time.

Parameter	Description
max-allowed-negotiations	Shows the maximum ongoing exchanges allowed at a time. If the exchanges cross this limit, IKE_SA_INIT packets are throttled. The maximum value is set based on the platform.
ppk	Shows configured PPK IDs.
server-certificate	Shows all the IKE server certificates used to authenticate the managed device for VPN clients.
vpn-peer-passcode	Show vpn-peer passcoder.
xauth	Shows the IKE XAuth configuration for VPN clients.

Examples

The examples here show sample output for the **show crypto-local isakmp ca-certificate**, **show crypto-local isakmp certificate-group**, **show crypto-local isakmp dpd**, **show crypto-local isakmp key**, **show crypto-local isakmp ppk**, **show crypto-local isakmp server-certificate** and **show crypto-local isakmp xauth** commands:

```

  TrustedCA
    [<name> [alias | ALL | dates | fingerprint | hash | issuer | modulus | purpose
| serial | subject]]
  service-ocsp-responder [stats]
```

Descriptions

Execute this command to show local certificate, OCSP signer or responder certificate, and CRL data and statistics. Use the `show crypto-local pki` command to view all CRL and certificate status, OCSP client and OCSP responder status and statistics.

Parameter	Description
CRL	Shows the name, original filename, reference count and expiration status of all CRLs on this controller.
<name> ALL	Shows the version, signature algorithm, issuer, last update, next update, and CRL extensions and all other attributes of this CRL.
<name> crlnumber	Shows the number of this CRL.
<name> fingerprint	Shows the fingerprint of this CRL.
<name> hash	Shows the hash number of this CRL.

Parameter	Description
<name> issuer	Shows the issuer of this CRL.
<name> lastupdate	Shows the last update (date and time) at which the returned status is known to be correct.
<name> nextupdate	Shows the next date and time (date and time) where the responder retrieves updated status information for this certificate. If this information is not present, then the responder always holds up to date status information.
crl-stats	Shows the CRL request statistics.
IntermediateCA	Shows the name, original filename, reference count and expiration status of this certificate. NOTE: IntermediateCA has the identical sub-parameters as those listed under the TrustedCA parameter in this table.
ocsp-client-stats	Shows the OCSP client statistics.
OCSPResponderCert	Shows the name, original filename, reference count and expiration status of all OCSPResponderCert certificates on this controller. NOTE: OCSPResponderCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.
OCSPSignerCert	Shows the OCSP Signer certificate. NOTE: OCSPSignerCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.
PublicCert	Shows Public key information of a certificate. This certificate allows an application to identify an exact certificate. NOTE: PublicCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.
rcp	Shows the revocation check point.
ServerCert	Shows Server certificate information. This certificate must contain both a public and a private key (the public and private keys must match). You can import a server certificate in either PKCS12 or X.509 PEM format; the certificate is stored in X.509 PEM DES encrypted format on the controller. NOTE: ServerCert has the identical sub-parameters as those listed under the TrustedCA parameter in this table.

Parameter	Description
TrustedCA	Shows trusted CA certificate information. This certificate can be either a root CA or intermediate CA. Aruba encourages (but does not require) the signing CA of the an intermediate CA to be the controller itself.
<name> ALL	Shows the version, signature algorithm, issuer, last update, next update, and CRL extensions and all other attributes of this certificate.
<name> alias	Shows this certificate's alias, if it exists.
<name> dates	Shows the dates for which this certificate is valid.
<name> fingerprint	Shows the certificate's fingerprint.
<name> hash	Shows the hash number of this certificate.
<name> issuer	Shows the certificate issuer.
<name> modulus	Shows the modulus which is part of the public key of the certificate.
<name> purpose	Shows the certificate's purposes such as if this is an SSL server, SSL server CA and so on.
<name> serial	Shows the certificate's serial number.
<name> subject	Shows the certificate's subject identification number.
service-ocsp-responder [stats]	Shows if OCSP responder service is enabled and shows statistics.

Example

This example displays a list of all OCSP responder certificates on this controller.

```
(host) [mynode] #show crypto-local pki OCSPResponderCert

Certificates
-----
Name                               Original Filename                Reference Count
Expired
-----
--
ocspJan28                          ocsprresp-jan28.cer              0                No
ocsprresp-standalone-feb21         ocsprresp-feb21.cer              0                No
ocsprrespFeb02                     ocsprresp-feb2.cer               1                No
OCSPResponder1                     ocsprresponder-new1.cer          0                No
ocspresponder2                     subsubCA-ocsp-res-2.cer          0                No
OCSPResponderlatest                ocsprresponder-latest.cer        0                No
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the OCSP responder certificate.
Original Filename	Name of the original certificate when it was added to the controller.
Reference Count	Number of RCPs that reference this OCSP responder certificate, signer certificate or CRL.
Expired	Shows whether the controller has enabled or disabled client remediation with Sygate-on-demand-agent.

This example shows the dates for which this OCSP responder certificate is valid.

```
(host) [mynode] #show crypto-local pki OCSPResponderCert ocsJan28 dates
notBefore=Jan 21 02:37:47 2011 GMT
notAfter=Jan 20 02:37:47 2013 GMT
```

This example displays the certificate's hash number.

```
(host) [mynode] #show crypto-local pki OCSPResponderCert ocsJan28 hash
91dcb1b3
```

This example shows the purpose and information about this certificate.

```
(host) [mynode] #show crypto-local pki OCSPResponderCert ocsJan28 purpose
Certificate purposes:For validation
SSL client : No
SSL client CA : No
SSL server : No
SSL server CA : No
Netscape SSL server : No
Netscape SSL server CA : No
S/MIME signing : No
S/MIME signing CA : No
S/MIME encryption : No
S/MIME encryption CA : No
CRL signing : No
CRL signing CA : No
Any Purpose : Yes
Any Purpose CA : Yes
OCSP helper : Yes
OCSP helper CA : No
```

This example displays the certificate's subject.

```
(host) [mynode] #show crypto-local pki OCSPResponderCert ocsJan28 subject
subject= /CN=WIN-T1BQQFMVDED.security1.qa.mycorp.com
```

Related Commands

show crypto pki

```
show crypto pki csr
  CRL
  csr
  IntermediateCA
  OCSPResponderCert
  OCSPSignerCert
  PublicCert
  ServerCert
  TrustedCA
```

Descriptions

This command displays different certificates, Certificate Revocation List (CRL), and certificate signing request (CSR) for the captive portal feature.

Parameter	Description
CRL	Displays Certificate Revocation List (CRL).
csr	Displays the certificate signing request for the captive portal feature.
IntermediateCA	Displays an intermediate CA certificate
OCSPResponderCert	Displays a OCSP Responder certificate
OCSPSignerCert	Displays a OCSP Signer certificate
PublicCert	Displays a public certificate
ServerCert	Displays a server certificate
TrustedCA	Displays a trusted CA certificate

Examples

The output of the `crypto pki csr` command.

```
(host) [mynode] #show crypto pki csr

Related Commands

Command	Description
crypto pki	Use this command to generate a certificate signing request (CSR) for the captive portal feature.
crypto pki-import	Use this command to import certificates for the captive portal feature.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show database

show database synchronize

Description

This command displays database synchronization status.

Parameter	Description
synchronize	Shows Multiple Master/Conductor Switches redundancy status (Master/Conductor-Master/Conductor communication).

Example

The following example displays a database synchronization status.

```
(host) [mm] (config) #show database synchronize

Last L2 synchronization time: Tue Oct 1 05:38:25 2019
Last L3 synchronization time: Tue Oct 1 04:26:09 2019
To Master/Conductor Switch at 192.168.228.4: succeeded
To Secondary Master/Conductor Switch at 2002:192:168:229::19: succeeded
WMS Database backup file size: 147035 bytes
Upgrademgr Database backup file size: 3397 bytes
Cluster upgrademgr Database backup file size: 3893 bytes
Local User Database backup file size: 37733 bytes
Global AP Database backup file size: 63738 bytes
IAP Database backup file size: 3778 bytes
Airgroup Database backup file size: 3076 bytes
License Database backup file size: 15419 bytes
CPSec Database backup file size: 3224 bytes
Bocmgr Database backup file size: 6062 bytes
Total size of Captive Portal Custom data: 0 bytes, 0 files
Total size of Captive Portal Custom data last synced: 0 bytes, 0 files
L2 Synchronization took 4 second
L3 Synchronization took 11 second
1289 L2 synchronization attempted
15 L2 synchronization have failed

10 L3 synchronization attempted
0 L3 synchronization have failed

L2 Periodic synchronization is enabled and runs every 1 minute

L3 Periodic synchronization is enabled and runs every 120 minutes
Synchronization doesn't include Captive Portal Custom data
Airmatch database gets synchronized periodically. Last synchronization time
: 20
```

Related Commands

Command	Description
<u>database synchronize</u>	This command configures the Mobility Conductor to synchronize the database with a standby or backup Mobility Conductor. This works in config mode.
<u>database-synchronize</u>	This command synchronizes the Mobility Conductor database with a standby or backup Mobility Conductor.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .
ArubaOS 8.6.0.0	The output was modified to include IPv6 address of the peer Mobility Conductor in Layer-2 and Layer-3 redundancy.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or config mode on Mobility Conductor.

Description

Displays system statistics for the managed device. Use the `show datapath` command to display various datapath statistics for debugging purposes.

MTU guidelines

- Since MTU discovery is not enforced between an AP and standby controller in a HA setup, the value of the MTU to be passed through the tunnel is not updated.
- The size of the MTU can be set to 9000, depending on the network link and AP configuration.
- In case of a heartbeat tunnel, unanswered larger frames for MTU discovery are counted as heartbeat misses.

Parameter	Description
<code>acl</code>	Displays datapath ACL entries.
<code>ap-name <ap-name></code>	Specify the name of the AP.
<code>id <id-name> [verbose]</code>	Displays datapath statistics associated with a specified ACL. The ACL index is found in the <code>show rights</code> command. The allowed range is 1-2703.
<code>ip-addr <ip-addr></code>	Specify the IP address of the AP.
<code>name <acl-name></code>	Specify the name of ACL.
<code>type <acl-type></code>	Specify the ACL Type. 0 - session-based; 1- role-based
<code>allowed-address-list</code>	Datapath allowed address list table
<code>counters</code>	Lists the number of IPv4 and IPv6 allowed addresses.

Parameter	Description
amsdu tx	Shows datapath AMSDU TX queue statistics
app-monitoring-list	Shows Airslice app monitoring list
application	Shows datapath application statistics. By default, it provides combined statistics of all CPUs.
<id>	Shows datapath application statistics by specified CPU id. Valid platform CPU range may vary.
all	Shows datapath application statistics for all CPUs, one by one.
ap-name <ap-name>	Specify the name of the AP.
counters	Shows application counters and errors generated by applications running on a particular AP. These include stateful firewall application layer statistics.
ip-addr <ip-addr>	Specify the IP address of the AP.
verbose	Shows datapath application statistics in detail.
bridge	Shows bridge table entry statistics including MAC address, VLAN, assigned VLAN, Destination, and flag information for an AP.
ap-name <ap-name>	Specify the name of the AP. Shows MAC address, VLAN, assigned VLANs, destination and flags information.
counters	Shows datapath bridge table statistics such as current entries, high water mark, maximum entries, total entries, allocation failures, and max link length.
devices	Shows datapath bridge devices.
ip-addr <ip-addr>	Specify the IP address of the AP. Shows MAC address, VLAN, assigned VLANs, destination and flags information.
table <macaddr>	Displays the current high, maximum, and total number of bridge table entries for the Aruba controller.

Parameter	Description
verbose	Displays datapath bridge details in a tabular format.
bwm	<p>Displays the following bandwidth management table entry statistics:</p> <ul style="list-style-type: none"> ▪ Type: Indicates whether the contract is a control plane DoS contract (0), a contract configured through the bandwidth management WebUI or CLI Interfaces (1), or a contract for multicast traffic generated by the controller(2). ▪ Cont ID: An ID number unique to each contract. ▪ Rate: Contract traffic rate, in 256-byte packets per second. ▪ Policed: The number of packets dropped because the policy was applied. ▪ Avail Credits: This value is the (contract rate) per 32, and is used for internal debugging purposes. ▪ Queued Pkts/ Bytes: Number of bytes or packets currently being queued. ▪ Flags: Flags applied to the contract. ▪ CPU: A value in this column indicates that the traffic passed through the slowpath CPU, and is used for internal debugging purposes. ▪ Status: Indicates if the bandwidth contract is successfully applied.
ap-name <ap-name>	View a bandwidth contract for a specific AP.
ip-addr <ip-addr>	View a bandwidth contract for an AP with the specified IP address.
table	Displays a table of all configured bandwidth contracts.
type <type-id>	Displays only bandwidth contracts of a specific type (0,1 or 2).

Parameter	Description
<code>contract <contract-id></code>	Displays the bandwidth contracts for the specified contract id.
<code>cluster</code>	Displays datapath cluster statistics.
<code>details</code>	Displays heartbeat counters in detail with missed and delayed sequence numbers.
<code>peer <peer_ip></code>	Displays detailed cluster statistics for a specified peer.
<code>heartbeat counters</code>	Displays cluster heartbeat counters.
<code>compression</code>	Displays datapath compression statistics. By default, the combined statistics of all CPUs are shown.
<code><id></code>	Shows datapath compression statistics by specified CPU id. Valid platform CPU range may vary.
<code>all</code>	Shows datapath compression statistics for all CPUs, one by one.
<code>counters</code>	Shows datapath compression counters or statistics.
<code>verbose</code>	Shows datapath compression statistics in detail.
<code>cp-bwm</code>	Displays the data path CP bandwidth management table information.
<code>table</code>	Displays the datapath CP bandwidth management table entries.
<code>crypto</code>	Displays crypto parameter statistics including crypto, IPsec, PPTP, WEP, TKIP, AESCCM encryption and decryptions, WEP CRC, crypto hardware, XSEC, 802.1X, and L2TP information.
<code><id></code>	Shows datapath crypto statistics by specified CPU id. Valid platform CPU range may vary.
<code>all</code>	Shows datapath crypto statistics for all CPUs, one by one.

Parameter	Description
counters	Shows datapath crypto counters or statistics.
verbose	Shows datapath crypto statistics in detail.
debug	Displays datapath debug details. These are low-level datapath details.
dma [counters]	DMA statistics are displayed.
eap [counters]	EAP termination statistics are displayed.
ethlinfo	Displays IPv4 fragment table statistics.
memory	Displays SOS memory statistics.
memory-usage	Displays datapath memory used.
opcode	Displays datapath debugging information. NOTE: Use this command only under the supervision of Aruba technical support.
performance	Displays datapath debug performance statistics including the SUM or CPU, addr, and description.
<id>	Displays datapath performance counters by specified CPU ID.
all	Displays datapath debug performance for all CPUs.
counters	Displays datapath performance counters.
event-guide	Displays the following events: <ul style="list-style-type: none"> ▪ COPO ▪ L3 Cache ▪ NAE-RX ▪ NAE-TX events (by register index 0-4)

Parameter	Description
verbose	Displays debug performance statistics including: SUM or CPU, address, description, value, and difference from last show.
pktrace-buffer [log {<number> all}]	Shows the datapath packet trace buffer from log file, either as number of lines from the end or as complete packet trace log.
table-limits	Displays the datapath table upper limits.
tnl-stats [<id> all counters verbose]	Displays the Wi-Fi Tunnel Stats Exported to CP debug.
trace-buffer [lines <lines>]	Shows the datapath trace buffer, by number of lines from the end of log.
trace-route	Shows datapath route or cache tracing.
dhcp vm-mac	Shows datapath DHCP-related information; datapath VM to host client MAC mapping
dns-cache [counters]	Displays DNS cache statistics.
dppk mempool-stats ring-stats	Data Plane Development Kit. <ul style="list-style-type: none"> mempool-stats—Shows datapath DDPK memory pool statistics. ring-stats—Shows datapath DDPK ring statistics.
dpi app-category <appcatid> application <appid>	Displays the DPI application default ports. Specify the application Group ID or the application ID.
energy-efficiency	Displays the energy efficiency statistics.
error	Displays datapath error statistics or counters.
counters	Show datapath errors including SUM, CPU, Address, and description information. The output counters include, but not limited to, the following: <ul style="list-style-type: none"> BPDUs Received VOQ retries Invalid IP headers Received IKE Throttle

Parameter	Description
	<ul style="list-style-type: none"> ▪ VOQ retries ▪ Ipv4 Firewall Denied Frames ▪ Ipv6 Firewall Denied Frames ▪ IP Reassembly Failures ▪ Invalid IP headers Received ▪ Dot1Q Discards ▪ Dot1d Discards ▪ Drop cache frames ▪ AESCCM Encryption Station Not Ready ▪ AESCCM Decryption Failures ▪ AESCCM Decryption Invalid Replay Co
esi [table]	Displays the contents of the datapath ESI server table entries including server, IP, MAC, destination, VLAN, type, session and flag information.
exception counters	Displays the datapath debug exception statistics.
exthdr	Displays the datapath default IPv6 Extended Header Map.
firewall-agg-sess	Displays the datapath firewall aggregated sessions table.
counters	Displays the datapath aggregate session statistics.
fqdn	Displays datapath FQDN entries.
frame	<p>Displays frame statistics that are received and transmitted from the data path of the controller. Several output fields include the following descriptions:</p> <ul style="list-style-type: none"> ▪ Descr failures: This is the number of times a packet descriptor was not available and the packet dropped. ▪ Dot1QDiscards: The number of packets received on a trunk port where the VLAN presented did not match any configured on the controller and the packet dropped. ▪ Dot1d Discards: Spanning tree is disabled and each BPDU frame is

Parameter	Description
	<p>counted and dropped.</p> <ul style="list-style-type: none"> ▪ Denied Frames: Frames that are denied by the data path of the ACL for the controller. ▪ Spoofed MAC: Displays information about spoofed MAC frames. <p>See the Example section for a complete list of output.</p>
<id>	Displays datapath frame statistics by specified CPU ID. Valid platform CPU range may vary.
all	Displays datapath frame statistics for all cpus, one by one.
ap-name <ap-name> [counters]	Name of the AP. The <code>counters</code> parameter is optional.
counters	Displays datapath frame statistics
ip-addr <ip-addr> [counters]	IP address of the AP. The <code>counters</code> parameter is optional.
slot	Displays datapath combined frame statistics of all CPUs, including slot specific section.
verbose	Displays datapath frame statistics in detail.
hardware	Displays datapath hardware counters or hardware packet statistics information.
counters	Displays hardware counters.
statistics	Displays Hardware packet statistics.
heartbeat stats	Displays Sibyte heartbeat packet stats.
internal	Displays Internal details .
dir <dir-name>	Specify the hardware directory.
file <file-name>	Specify the file in the directory.

Parameter	Description
ip-fragment-table	Displays ip-fragment statistics including CPU, current entries, high water mark, max , total, and aged entries.
ipv4	Displays IPv4 fragment statistics.
ipv6	Displays IPv6 fragment statistics.
ip-geolocation	Datapath IP geolocation table entries.
counters	Displays IP geolocation statistics.
ip-mcast	Displays the Datapath IP Multicast Entries table statistics.
client <client-mac>	Datapath Layer 3 groups for specified client.
destination	Datapath tunnel and port membership.
group	Datapath Layer 3 groups.
station	Datapath station membership.
ip-reassembly	Displays the contents of the IP Reassembly statistics tables.
counters	IP reassembly counters.
ipv4	Displays the IPv4 contents of the IP Reassembly statistics table.
ipv6	Displays the IPv6 contents of the IP Reassembly statistics table.
ip-reputation	Datapath IP reputation table entries.
counters	Displays IP reputation statistics.
rtc	Displays IP reputation real time cache.
ipfix statistics	Displays datapath IPFIX collection statistics.
ipsec-map	Displays datapath IPsec map details.
ipv6-mcast	Displays the datapath IP multicast table statistics.

Parameter	Description
destination	Displays the IPv6 tunnel and port membership.
group	Displays the IPv6 multicast group.
station	Displays the IPv6 station membership.
l3-interface	Displays datapath Layer 3 interface table.
lag table	Displays contents of the datapath LAG or port channel table.
maintenance [counters]	Displays datapath maintenance statistics.
message-queue [counters]	Displays statistics of messages received by a CPU from other datapath CPUs (only CPUs that receive messages and non-zero statistics are shown). The datapath SOS message queue statistics by CPU IDs and Opcode is displayed.
mobility	Displays datapath IP mobility information.
discovery-table	Displays the discovery count table that is used to keep track of per client home agent discovery.
home-agent-table	Displays the datapath HA table information.
mcast-table	Displays the mobility multicast-group table that is used to flood the multicast RA traffic to the roamed clients.
stats	Displays the statistics of the datapath mobility.
nat	Displays the contents of the datapath NAT entries table. It displays NAT pools as configured in the datapath. Statistics include pool, S1TP start, S1P end and DIP.
ap-name <ap-name> [table]	Specify the name of AP.
ip-addr <ip-addr> [table]	Specify the IP address of the AP.
table	Shows the datapath NAT table entries.

Parameter	Description
<pre>netdest-id ap-name <ap-name> ip-addr <ip-addr> <id></pre>	<p>Shows the datapath ACL netdestination table. for AP name, IP address of AP, or ID.</p>
<pre>network {egress ingress}</pre>	<p>Displays egress or ingress queue counters. The network egress output includes, but not limited to, the following fields:</p> <ul style="list-style-type: none"> ▪ CPU ▪ DP High Prio ▪ Network High Prio <p>The network ingress output includes, but not limited to, the following fields:</p> <ul style="list-style-type: none"> ▪ LIFO Queue ▪ Threshold count ▪ Empty Count ▪ Threshold Recovery ▪ Empty Recovery
<pre>nexthop-list [ipv4 ipv6]</pre>	<p>Displays information about the datapath for packets routed to next-hop devices. The output contains the following parameters:</p> <ul style="list-style-type: none"> ▪ Dest ▪ Version ▪ Nexthop ▪ Nexthop Dest ▪ Nexthop Index ▪ Nexthop Version ▪ Nexthop VLAN ▪ Nexthop Priority
<pre>openflow</pre>	<p>Displays the datapath OpenFlow information.</p>
<pre>acl</pre>	<p>Displays the datapath OpenFlow ACL table and actions.</p>
<pre>acl-action-table</pre>	<p>Displays the OpenFlow ACL action table.</p>
<pre>auxiliary</pre>	<p>Displays the datapath OpenFlow auxiliary channel information.</p>
<pre>session [<A.B.C.D>]</pre>	<p>Displays the datapath OpenFlow session table and actions. You can optionally filter the sessions based on the IP address.</p>

Parameter	Description
statistics	Displays the OpenFlow statistics in datapath.
outstanding-buffers	Displays the datapath per-station outstanding buffer statistics.
papi	Displays the datapath PAPI statistics.
counters	Displays datapath PAPI counters including: SUM or CPU, addr, description, and value.
remote-device-table [ipv6]	Displays the remote device table maintained in the datapath that contains PAPI entries for IPv6 devices.
port	Displays the datapath port table information. This includes the port number, PVID, Ingress ACL, Egress ACL, Session ACL, and the following flags: <ul style="list-style-type: none"> ▪ B: Blocked by the Spanning Tree protocol ▪ L: LSG ▪ M: Tunneled node ▪ Q: Trunk ▪ T: Trusted ▪ X: xSec ▪ Z: QinQ
ap-name <ap-name> [table]	Specify the name of the AP. Shows the datapath port table entries for the specified AP.
ip-addr <ip-addr> [table]	Specify the IP address of the AP. Shows the datapath port table entries for the specified IP.
untrusted-vlan <slot>/<module>/<port>	Shows if there are untrusted vlan entries for the indicated slot, module, and port.
vlan-table <slot>/<module>/<port>	Shows datapath port-vlan table session entries for the specified slot, module, and port.
rap-bw-resv ap-name <ap-name> [advanced] ip-addr <ip-addr> [advanced]	Displays the remote AP uplink BW reservation statistics of the Remote AP only. Specify the AP or IP address with the <i>advanced</i> parameter for Advanced Debugging Options.

Parameter	Description
<pre>rap-pkt-trace ap-name <ap-name> ip-addr <ip-addr></pre>	Specify the name of the Remote AP. Displays the remote AP packet-trace statistics of only the specified Remote AP.
<pre>rap-stats ap-name <ap-name> ip-addr <ip-addr></pre>	Specify the name of the Remote AP. Displays the remote AP statistics of only the specified Remote AP.
remote-user table	Displays the remote user table.
ipv4	Displays the IPv4 entries of the remote user table.
ipv6	Displays the IPv6 entries of the remote user table.
role-cp-table	Displays the user-role to captive-portal mapping table.
route	<p>Displays datapath route table statistics. The output of the command includes the following fields:</p> <p>Route table entries</p> <ul style="list-style-type: none"> ▪ IP ▪ Mask ▪ Gateway ▪ Cost ▪ VLAN ▪ Flags <p>IPv6 Route table entries</p> <ul style="list-style-type: none"> ▪ Prefix ▪ Gateway ▪ Cost ▪ VLAN ▪ Flags
<pre>ap-name <ap-name> [counters table verbose]</pre>	Specify the name of the AP.
counters	Displays route table statistics such as current entries, high water mark, maximum entries, total entries, allocation failures and max link length.
<pre>ip-addr <ip-addr> [counters table verbose]</pre>	Specify the IP address of the AP.
ipv4	Displays datapath IPv4 routing table.

Parameter	Description
ipv6	Displays datapath IPv6 routing table.
table	Displays route table entries such as IP, mask, gateway, cost, VLAN and flags.
verbose	Displays all detailed route table entries including IP, mask, gateway, cost, VLAN, flags, Internal VerNum Index.
route-cache	Displays datapath route cache table statistics.
ap-name <ap-name> [counters table verbose]	Specify the name of the AP.
counters	Displays route cache table statistics such as current entries, high water mark, maximum entries, total entries, allocation failures and max link length.
ip-addr <ip-addr> [counters table verbose]	Specify the IP address.
ipv4	Displays datapath IPv4 route cache.
ipv6	Displays datapath IPv6 route cache.
table	Displays route cache table entries such as IP, mask, gateway, cost, VLAN and flags.
verbose	Displays all detailed route cache table entries including IP, mask, gateway, cost, VLAN, flags, Internal VerNum Index.
scheduler interface <slot/module/port> table	Displays the datapath scheduler table. Specify interface for scheduler output in the slot or module or port format.
services	Displays the datapath services table statistics including protocol, port and service.
session	Displays datapath session statistics. The command output includes, but not limited to, the following fields: <ul style="list-style-type: none"> ▪ Source IP ▪ Destination IP ▪ SPort ▪ DPort ▪ Prio

Parameter	Description
	<ul style="list-style-type: none"> ▪ ToS ▪ Age ▪ Destination ▪ TAge ▪ Packets ▪ Bytes ▪ NhIdx ▪ NhIdx ▪ NhINhVer
<pre>ap-name <ap-name> [counters table [<A.B.C.D>]]</pre>	Specify the name of the AP. Counters and table are optional parameters
counters	Displays counters statistics including current entries, high water mark, maximum entries, total entries, current maximum link length, maximum link length, stale entries, aged entries, and pending delete entries.
dhcp-perf	Displays the performance details of datapath DHCP sessions.
<pre>dpi [counters [all top uplink-vlan <uplinkvlan>]]</pre>	<p>Displays Deep Packet Information for this session. The counters parameter is optional.</p> <p>The output includes, but not limited to, the following fields:</p> <ul style="list-style-type: none"> ▪ AcIVersion: This is used to store the current version number of the ACL that is used at session creation time and is used for troubleshooting purposes. ▪ PktsDpi: The number of packets sent to the DPI engine for a given session. ▪ AcIdx: The Index of the Access List entry (in a given ACL) that triggered a match during session creation. ▪ DpiTIdx: This is an index to the DPI engine Tbl and is only used for troubleshooting purposes.
high-value	Shows high- value sessions statistics.
<pre>ip-addr <ip-addr> [counters table [<A.B.C.D>]]</pre>	Specify the IP address of the AP. The counters and table parameters are optional.

Parameter	Description
ip-classification	IP reputation or geolocation information for session.
<pre> ipv6 counters dhcp-perf dpi [counters [top] high-value perf table [<X:X:X:X::X>] appid <app-id>] table <X:X:X:X::X> verbose web-cc [counters dpi] </pre>	Displays datapath IPv6 session entries and statistics including current entries, high water mark, maximum entries, total entries, allocation failures, duplicate entries, cross linked entries, number of reverse entries and maximum link length.
perf	Displays the performance monitored for each datapath session.
session-id <sid> [dpi]	Displays datapath session FIB for a given session index. The optional <code>dpi</code> parameter displays the deep packet information for session.
table [<A.B.C.D>]	Displays all the IP flows of a wireless device or Aruba AP. Statistics include table entries including source IP, destination IP, protocol, SPort, DPort, Cntr, priority, ToS, age, destination, TAge and flags.
uplink	Displays statistics of datapath session with uplink VLAN.
verbose	<p>Displays additional information about the session that can be used by technical support for debugging purposes.</p> <p>The command output includes, but not limited to, the following additional fields:</p> <ul style="list-style-type: none"> ▪ SIDX ▪ SRTI ▪ SRCI ▪ UsrIdx ▪ UsrVer ▪ AcIVer ▪ NhIdx ▪ NhVer

Parameter	Description
web-cc	<p>Displays web-content category information about the session. The output of this command includes but not limited to the following data columns:</p> <ul style="list-style-type: none"> ▪ WebCCRep: Reputation score (integer). To see the reputation type associated with that particular score, issue the command show web-cc reputation. ▪ WebCCID: Web content category ID. To see the name of the category associated with that category ID, issue the command show web-cc category. ▪ WebCCURL: URL for that session entry.
station	Displays datapath station association table statistics.
<id>	Shows datapath station statistics by specified CPU id. Valid platform CPU range may vary.
all	Shows datapath station for all CPUs, one by one.
counters	Display the current and high water mark amount of 802.11 associated wireless devices on a controller. Values output from this command represent the water-marks since the last boot of the controller. This is the same value obtainable from the Num Associations output from the <code>show stm connectivity</code> command.
crypto-counters	Displays datapath station crypto counters or statistics.
mac <macaddr>	Specify the hardware address, in hexadecimal format (48-bit, station's MAC address). Shows the datapath station association with a specific MAC.
standby	Shows datapath station associated as standby.
table	Shows datapath station associations.

Parameter	Description
verbose	Shows the datapath station detail.
tcp	Displays contents of the tcp tunnel table. This command displays all TCP tunnels that are terminated by the controller.
app <app> [counters]	Specify the name of the application.
counters	Displays the TCP tunnel statistics.
tunnel table	<p>Displays the TCP tunnel table entries. This command displays the Datapath Station Table Statistics details. Display all associated wireless devices on the controller with their corresponding AP BSSID and VLAN ID. Displays the wireless device is associated with the correct encryption type (if the device is associated to an AP BSSID that has encryption enabled and verifies whether the controller is having a problem in decrypting the wireless device's frames.</p>
tcp	Displays contents of the datapath tcp table.
tunnel	<p>Displays contents of the datapath tunnel table. This command displays all the tunnels that are terminated by the controller, including the GRE tunnels of Aruba AP. For example, a GRE tunnel is created and terminated on the Aruba controller for every SSID or BSSID configured on the Aruba AP. The output of the command includes, but not limited to, the following fields:</p> <ul style="list-style-type: none"> ▪ Source ▪ Destination ▪ Port ▪ Type ▪ MTU ▪ VLAN ▪ ACLs ▪ BSSID ▪ Decaps ▪ Encaps ▪ Heartbeats ▪ Flags ▪ Encap Bytes

Parameter	Description
	<ul style="list-style-type: none"> Decap Bytes <p>NOTE: The MTU size is 9216 bytes when Jumbo frames are enabled in an IPsec site-to-site tunnel between two managed devices. The supported range has changed from 1024-1500 to 1024-9216 MTU size for an IPsec site-to-site tunnel between two managed devices when Jumbo frames are enabled.</p>
counters	Shows tunnel counters or statistics.
encaps	Shows datapath encapsulation statistics verbose.
heartbeat	Displays the datapath heartbeat tunnel details.
ipv4	Displays the TCP tunnel table filtered on IPv4 entries.
ipv6 [encaps verbose]	Displays the TCP tunnel table filtered on IPv6 entries. The encaps or verbose parameter is optional.
station-list	Displays the list of stations on the tunnel.
table	Tunnel table statistics.
tunnel-id <tid> [trusted-vlan untrusted-vlan]	Displays datapath tunnel FIB for given tunnel index. Displays the list of trusted and untrusted VLANs.
verbose	Shows datapath tunnel internal detail.
tunnel-group	Displays the tunnel group, active status and members.
user	Displays datapath user statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users and maximum link length.
<id>	Shows datapath user statistics by specified CPU id. Valid platform CPU range may vary.

Parameter	Description
all	Shows datapath user table for all CPUs.
ap-name <ap-name> [counters table]	Specify the name of the AP.
counters	User counters.
ip-addr <ip-addr> [counters table]	Specify the IP address of the AP.
ipv4	Displays datapath IPv4 user entries and statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users, and maximum link length.
ipv6	Displays datapath IPv6 user entries and statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users, and maximum link length.
table	User table statistics.
verbose	Shows datapath user table detail.
uplink verbose	Displays the datapath uplink table details.
utilization	Displays the current CPU utilization of datapath CPUs by CPU ID. The output of the command includes CPU ID and CPU utilization during the past 1 sec, 4 sec, and 64 sec.
vlan	Displays VLAN table information such as VLAN memberships inside the datapath including Layer 2 tunnels which tunnel L2 traffic. The output fields of the command are as follows: <ul style="list-style-type: none"> ▪ VLAN ▪ Flags ▪ Ingress RACL ▪ Ports
ap-name <ap-name> [table]	Specify the name of the AP. Shows the datapath VLAN details.
ip-addr <ip-address> [table]	Specify the IP address of the AP. Shows the datapath VLAN details

Parameter	Description
pvst	Displays the datapath VLAN table entries.
table	Displays VLAN number, flag, port and datapath VLAN multicast entries.
vlan-mcast	Displays the datapath VLAN multicast table. The output of this command displays the datapath VLAN Multicast entries for the following fields: <ul style="list-style-type: none"> ▪ VLAN ▪ Destinations
ap-name <ap-name> [table]	Specify the name of the AP. Displays the datapath VLAN multicast table for the specific AP.
ip-addr <ip-addr> [table]	Specify the IP address of the AP. Displays the datapath VLAN multicast table for the specific IP address.
table	Displays datapath VLAN Multicast table entries.
wan hc	Displays datapath WAN health check statistics. By default, combined statistics of all CPUs is shown.
<id>	Displays datapath WAN health check statistics by specified CPU ID. Valid platform CPU range may vary.
all	Displays datapath WAN health check statistics for all CPUs.
counters	Displays datapath WAN health check counters or statistics.
verbose	Displays datapath WAN health check detail.
web-cc [counters]	Displays web content classification table information. The output of this command includes but not limited to the following data columns: <ul style="list-style-type: none"> ▪ Rep ▪ ContentID ▪ TTL ▪ Age

Parameter	Description
	Include the optional <code>counters</code> parameter to display the maximum number of entries allowed in the web content category table.
<code>wifi-reassembly</code>	Displays Wi-Fi reassembly counters including CPU, current entries, high water-mark, maximum entries, total entries, and allocation failures.
<code><id></code>	Displays Wi-Fi reassembly statistics by specified CPU ID. Valid platform CPU range may vary.
<code>all</code>	Displays Wi-Fi reassembly statistics for all CPUs, one by one.
<code>counters</code>	Displays Wi-Fi reassembly counters or statistics.
<code>verbose</code>	Displays Wi-Fi reassembly detail.
<code>wmm [counters]</code>	Displays VOIP statistics, including the number of uplink and downlink resets.

Example

The following example displays information on network specific ingress-queue counters:

```

```

The output parameters of the `show datapath network ingress` command are explained in the following table:

Output Parameter	Description
LIFO Queue	<p>The number of the queue.</p> <p>NOTE: Packets ingressing the controller toward the NAE pass through one of 9 queues. Each queue holds a maximum 1000 packets at any one time which are taken from the queue by the NAE for forwarding.</p> <p>NOTE: The number of packets that each LIFO queue can hold is platform-specific and different for each queue. For example, 780 for Default queue 1 on 7000 Series controllers and 1580 on 7200 Series controllers.</p>
Description	The type of traffic assigned to the queue.
Packets received	The aggregate number of packets received since clearing the queues or restarting the controller.
Threshold Count	The number of times the input queue is below the built-in threshold value. Threshold counts are caused by Input queue congestion where the queue is depleted below the threshold value.
Empty Count	The number of times the Input queue is empty. Empty queue counts are caused by Input queue congestion where the queue is empty without any free descriptors.
Threshold Recovery	<p>The number of times the Input queue is below the built-in threshold value, but recovered to a number above the threshold value.</p> <p>NOTE: In a stable system, the Threshold Recovery and Threshold Count will match.</p>

Output Parameter	Description
Empty Recovery	The number of times the Input queue has recovered from empty to a normal condition to a built-in low threshold. In a stable system, the Empty Recovery and Empty Count will match.

The following example displays the discovery count table that keeps track of per client home agent discovery:

```
(host) [mynode] #show datapath mobility discovery-table
Datapath Mobility Discovery Count Table
-----
Index   Valid   Version  Retry#   No-Response  Ack   Mac
  Vlan
-----
-
1       1       2        1        a             0
10:78:D2:FA:7D:38  74
The following example displays the datapath HA table information:
(host) [mynode] #show datapath mobility home-agent-table
Datapath Mobility Home Agent Table
-----
Switch IP
-----
10.16.19.14
10.16.19.140
```

The execution of the following command displays the mobility multicast-group table that floods the multicast RA traffic to the roaming clients:

```
(host) [mynode] #show datapath mobility mcast-table
```

The following example displays the statistics of the datapath mobility:

```
(host) [mynode] #show datapath mobility stats
Datapath Mobility Stats
Mcast group entry alloc errors      : 0
Frames flooded over MMG (@HA)      : 0
Frames subjected to MMG (@FA)      : 0
Frames sent to roamed clients      : 0
HA Discovery failure to notify NACK : 0
HA Discovery invalid DCT           : 0
HA Discovery DCT allocation failed  : 0
HA Discovery Probes sent           : 0
HA Discovery NULL bridge entry in DCT : 0
HA Discovery failed to start       : 0
HA Discovery successfully started   : 0
HAT insert failure                 : 0
HAT insert success                 : 0
HAT delete failure                 : 0
```

```
HAT delete success : 0
```

The following example displays the mobility multicast VLAN table information:

```
(host) [mynode] #show ip mobile multicast-vlan-table
Mobility Multicast Vlan Table
-----
Client MAC          Home vlan  Current vlan
-----
40:2C:F4:36:16:07  501       501
```

The following example displays a list of tunnels.

```
(host) [mynode] #show datapath tunnel
+-----+-----+-----+-----+
|SUM/|          |          |          |

| G | [08] | Tunnel FIB recompute                1176170 |
+-----+-----+-----+-----+-----+-----+

```

The output parameters of the `show datapath tunnel counters` command are explained in the following table:

Output Parameter	Description
Current Entries	Number of established tunnels. A warning message is sent to the system log if the value of the <code>Current Entries</code> exceeds 80% of the <code>Maximum Entries</code> value for a controller.
Pending Deletes	Number of tunnel entries that are marked to be deleted.
High Water Mark	The maximum number of concurrently established tunnels at any given time since the last controller reboot.
Maximum Entries	Maximum number of tunnel entries that can be supported by the platform.
Total Entries	The total number of times a tunnel has been created since the last controller reboot. Only a tunnel UP event is considered. For example, if the same tunnel is created 5 times, then the total entries count increments by the value of 5.
Allocation Failures	Total number of tunnel entry allocation failures.
Max Link Length	Indicates the length of the linked list that has the maximum length in the hash table.
Current Tunnel FIB	Number of tunnel FIB entries that are recomputed and have a valid session entry and route cache entry.
Tunnel FIB Recompute	Number of invalid tunnel FIB entries for which tunnel FIB is recomputed.
Tunnel FIB forwarded	Number of packets that are forwarded through tunnel.
Tunnel FIB Egress Not Unicast	Number of packets whose bridge entry is not found or whose egress destination is not unicast.
GRE Encap drop	Number of packets that are dropped due to various reasons such as destination is not a tunnel, tunnel is not valid, packet length exceeded the allowed MTU, and so on.
GRE Encap fallback to session	Number of packets that are not permitted to be directly forwarded using tunnel FIB, but rather have to fall back to the session-route processing in the pipeline.

Output Parameter	Description
Tunnel FIB stale	Number of tunnel FIB entries that are invalid due to invalid session or tunnel version number not matching the session version number.

The following example displays a partial list of crypto parameter statistics.

```
(host) [mynode] #show datapath crypto counters
+-----+-----+-----+-----+
|SUM/|          |          |          |

| G | [000] | Crypto Accelerator Present     | TRUE |
+-----+-----+-----+-----+
```

The following parameters appear in the output of the `show datapath crypto counters` command, and are useful for debugging purposes.

Parameter	Description
Crypto BadNPlus	Indicates a queue overrun in the output of the encryption circuit.
Crypto SendNPlusFailed	Indicates a queue overrun in the input of the encryption circuit.
IPSec Frag Failures	This counter increments when the AP detects a failure to fragment a frame before or after IPsec encryption.
IPSec Invalid Length	The inbound IPsec frame length is verified before and after decryption. If the frame length is found to be incorrect, this counter is incremented.
IKE Rate	When the managed device firewall receives a UDP packet, it determines if the packet is destined for an IKE (500) or IPsec_NATT (4500) port. This counter increments when the AP receives an initial IKE packet that has an 8-byte responder cookie defined all 0s.

The following example displays the output of the `show datapath frame` and `show datapath frame counters` commands.

```
(host) [mynode] #show datapath frame
+-----+-----+-----+-----+
|SUM/|      |      |      |      |
|CPU | Addr | Description          |      | Value |

```

The following table provides description for some important output parameters of `show datapath frame` and `show datapath frame counters` commands:

Output Parameter	Description
Allocated Frames	Statically pre-allocated frames (for handling data-traffic) and dynamically allocated frames (for internal control-traffic).
Max Allocated Frames	Max watermark of Allocated Frames.
TX Underrun	Hardware counter if MAC was fetching packet data while packet is being transmitted.
TX Max Collision-Late Abort	Hardware counter if packet transmission was aborted due to maximum collision count exceeded (10 or 100 modes only) or a late abort.

Output Parameter	Description
Frame Denied L2-GRE Loop	Packets where Ingress and Egress are same (Enabled for Mobility feature only).
Unknown Unicast	Unknown dest-mac counter.
IPv6 Unknown Unicast	Unknown Unicast for IPv6 ethtype.
IP Datagrams Fragmented	IP datagrams fragmented when packet-length is greater than Tunnel MTU (Tunnel can be between controllers or controller and AP).
WIFI AMSDU	Wi-Fi A-MSDU frames received from Wi-Fi clients.
WIFI AMSDU Aggregated	A-MSDU frames sent by controller to Wi-Fi clients.
Runts Received	Packet length is less than minimum header length.
Station Not Data Ready	Packets received by a controller from the APs or Stations before they got provisioned.
Station Inactive	Packets received by a controller from the APs or Stations after they were inactive.
Association Throttle	Drops of APs or Stations Associate coming at high rate (e.g., during failover).
IKE Throttle	Drops of IKE packets coming at high rate.
IPv6 NA Spoofs	IPv6 Network Advertisement spoofs.
IPv6 NS Spoofs	IPv6 Network Solicitation spoofs.
EOP zero frames	Zero length frames.
CP Policed Frames	Packets bound to Control plane from Data plane dropped.
Seqno request failure	Wi-Fi Sequence no. request failed.
Heartbeats sent to SP	Tunnel Heartbeats punted to Slowpath (due to route-cache miss, etc.)
Heartbeats dropped by FP	Tunnel Heartbeats dropped in data plane.
POE descriptor freed	Internal counter
CP Enqueue Buffer Alloc Failure	Buffer allocation failures while sending packets to Control plane.

Output Parameter	Description
VOQ retries	Virtual Output Queues are packet exchanges between any two entities (CPU or Hardware offload engines) that have failed due to there not being any available credits. Packets are scheduled to be retried at a later point in time.
Seqno responses sent	The sequence number sent in response to sequence number requests used in Wi-Fi frames.
Dot1Q Discards	<p>The Dot1Q discard counter may increase as a result of the following:</p> <ul style="list-style-type: none"> ▪ An incoming frame's VLAN does not match a port's configured VLAN. ▪ A trunk port is not a member of the received frames's VLAN and the received frame is not an STP BPDU, CISCO BPDU or an LACP PDU. ▪ A received frame has three or more stacked (QnQ tagged) VLANs. ▪ A received frame contains more than one VLAN tag, however the expected number of VLAN tags is one. ▪ An untagged access port is not a member of the VLAN in the received frame. ▪ A station has sent a tagged VLAN frame. ▪ A received LLDP frame has no multicast destination. ▪ A received frame has no multicast destination in the VLAN group.
Dot1D Discards	<p>The Dot1d discard counter may increase as a result of the following:</p> <ul style="list-style-type: none"> ▪ If a port is in STP blocking state, then received frames are dropped. ▪ The tagged frame received on untagged port and dropped. ▪ Received frame length is less than (Ethernet + VLAN) header length. ▪ Frames that have been dropped due to bridge filtering. ▪ Port has MUX flag set but NULL egress destination. ▪ Frame drop either if destined for non-tunnel or to port channel or destination tunnel with no multicast configured. ▪ Dropped frames addressed to BPDU MACs but not configured in the bridge table. ▪ Dropped unexpected frames.

When the counter value is zero, the output parameter line is not displayed.

Some of the other output parameters that could be part of the `show datapath frame` command are as follows:

<ul style="list-style-type: none"> ■ IP Fragmentation Failures ■ IP Jumbo Fragmentation Failures ■ IP Jumbo IPSec Encryption Failures ■ IP Reassembled Datagrams ■ IP Reassembly overlaps ■ IP Reassembly PAPI Failures ■ IP Reassembly PAPI ■ IP Reassembly Failures ■ IPv6 Datagrams Fragmented ■ IPv6 Fragmentation Failures ■ IPv6 Reassembled Datagrams ■ IPv6 Reassembly overlaps ■ Invalid IP headers Received ■ Invalid IPv6 headers Received ■ Too Many IPv6 Ext. Hdrs Received 	<ul style="list-style-type: none"> ■ xSec Frames Re-Assembled ■ xSec Re-Assembly Failures ■ Flood Frames ■ Flood Frames Peak Value ■ ARP Request Spoofs ■ ARP Reply Spoofs ■ Gratuitous ARP Spoofs ■ IP spoofs ■ CPU based seqno resp ■ Frame Length Failure ■ Packet send failed and will be retried later ■ Invalid Tail Room DDMO ■ Invalid mcast entry ■ Jumbo Wi-Fi Frames ■ Invalid ingress frames ■ Invalid egress frames ■ Invalid opcode ■ Invalid Port ■ Invalid Slot ■ Invalid ACL ■ Jumbo discards 	<ul style="list-style-type: none"> ■ Jumbo recvd ■ Jumbo xmits ■ Jumbo drops ■ Jumbo wire to wireless drops ■ Jumbo xmits Failures ■ Jumbo drops [Non Jumbo Port] ■ Jumbo drops [Wireless client] ■ Flooded Jumbo Frames ■ Buffer Alloc Failure ■ NAE Transmit Failure ■ Total queued BWM packets ■ Excessive ARP Requests ■ Drops - DPI enforcement ■ Drops - WEB CC enforcement ■ IPv6 Vlan Discards ■ Drops - Wireless client garps
---	---	--

The following is an example of the `show datapath compression` command output:

```

+-----+-----+-----+-----+
|SUM/|      |      |      |      |
|CPU | Addr | Description |      | Value |
+-----+-----+-----+-----+
|    | [00] | Compression Engine Present |      | True |
|    | [01] | Comp Response received |      | 150 |
|    | [02] | Comp Response failed |      | 0 |
|    | [03] | Decomp Requests |      | 80 |
|    | [04] | Decomp Response received |      | 80 |
|    | [05] | Decomp Requests queued |      | 75 |
| G  | [06] | Compression Engine Total |      | 4 |
+-----+-----+-----+-----+

```

When the counter value is zero, the output parameter line is not displayed.

The following example displays the output of the `show datapath bwm table` command:

```

(host) [mynode] #show datapath bwm table
Datapath Bandwidth Management Table Entries
-----

```

If the policed counter is a non-zero value, it means excessive traffic of that type that has been dropped to avoid saturating the Control Plane, resulting in potential DoS.

The following table provides description for the contract IDs 1-10 as well as the corresponding firewall parameters:

Contract ID	Contract Description	Firewall Parameter
1	Rate limit Control-Plane-bound untrusted unicast packets. It is used to limit Web CC traffic to CP.	untrusted-ucast

Contract ID	Contract Description	Firewall Parameter
2	Rate limit Control-Plane-bound untrusted multicast packets. It limits ACL logging, packet capture traffic.	untrusted-mcast
3	Rate limit Control-Plane-bound trusted unicast packets.	trusted-ucast
4	Rate limit Control-Plane-bound trusted multicast packets.	trusted-mcast
5	Rate limit Control-Plane-bound routed packets.	route
6	Rate limit Control-Plane-bound GRE control-plane session mirrored packets.	sessmir
7	Rate limit Control-Plane-bound authentication-related packets.	auth
8	Rate limit Control-Plane-bound VRRP protocol packets.	vrrp
9	Rate limit Control-Plane-bound ARP protocol packets	arp-traffic
10	Rate limit Control-Plane-bound other Layer-2 or bridging packets - Non-ARP traffic.	l2-other
11	Rate limit Control-Plane-bound IP error packets.	ippkt-err

The following example displays the IPv6 route table entries of AP datapath in Spit-Tunnel forwarding mode for Remote APs:

```
(host)[mynode] #show datapath route ap-name ap303 ipv6
IPv6 Route Table Entries
-----
Flags: L - Local, P - Permanent, T - Tunnel, I - IPsec, M - Mobile, A -
ARP, D - Drop

  Prefix          Gateway          Cost  VLAN  Flags
  -----
::/0              fe80::eaf7:24ff:fe46:2ee1  0     0
2001:603::/64    2001:603::159b      0     1     L
```

The following example displays the IPv6 route cache entries of AP datapath in Spit-Tunnel forwarding mode for Remote APs:

```
(host)[mynode] #show datapath route-cache ap-name ap325 ipv6
Neighbour/Route Cache Entries
-----
```

```
Flags: L - Local, P - Permanent, T - Tunnel, I - IPsec, M - Mobile, t-
trusted, A - ARP, D - Drop, R - Route across vlan
O - Temporary, N - INactive, i - Mixed Mode IPsec
```

IP	MAC	VLAN	Flags
2001:384::250	E8:F7:24:46:2E:E1	1	
2001:603::41c	AC:A3:1E:CD:3C:F0	1	LP

Related Commands

Command	Description
datapath	This command configures datapath options.

Command History

Release	Modification
ArubaOS 8.8.0.0	A new parameter, <code>allowed-address-list</code> was added.
ArubaOS 8.7.0.0	The command outputs are modified to include the following: <ul style="list-style-type: none"> A new flag, X is introduced for <code>show datapath tunnel</code> command. The <code>show datapath session dpi</code> command displays the AirSlice ID.
ArubaOS 8.6.0.0	The following changes were introduced:

Release	Modification
	<ul style="list-style-type: none"> ▪ The <code>remote-user table</code> parameter was added. ▪ The ipv6 option was added to the <code>nexthop-list</code> sub-parameter. ▪ The output of the <code>show datapath session ipv6</code> command was modified to display the next-hop list details, and includes the NhIIdx, NhIdx, and NhINhVer columns. ▪ The output of the <code>show datapath ipsec-map</code> command was modified to display v6 value under IP ver column.
ArubaOS 8.4.0.0	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ▪ The output of the <code>#show datapath tunnel ipv6</code> command was modified to include B, G, and Y flags. ▪ The output of the <code>show datapath route ap-name <ap-name> ipv6</code> and <code>show datapath route-cache ap-name <ap-name> ipv6</code> commands was modified to display IPv6 route entries. ▪ The <code>web-cc</code> and <code>counters</code> sub-parameters were added to <code>ipv6</code> parameter. ▪ The output of the <code>show datapath session ipv6 web-cc</code> command was modified to display WebCC related entries for IPv6 sessions. ▪ The <code>trusted-vlan</code> and <code>untrusted-vlan</code> sub-parameters were introduced in the <code>show datapath tunnel tunnel-id <id></code> command.
ArubaOS 8.2.0.0	The <code>netdest-id</code> , and <code>remote-device-table</code> parameters were added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show datapath cluster details

show datapath cluster details
peer <peer ip>

Description

Displays the following information:

- Global data - Heartbeat threshold values, databath assignments, and number of peers.
- Peer data - Peer statistics for cluster heartbeat requests sent, responses received, and heartbeats missed, and so on.

Parameter	Description
peer <peer ip>	Displays peer data statistics

Example

An example output of the show datapath cluster details command.

```
#show datapath cluster details

show dds debug

```
global_object_db [peer <A.B.C.D> [rkey <rkey-id>] |peerv6 <X:X:X:X::X>]
message-stats
peers
rkey
replicaton <sources>
stats
```

Description

This command shows the dds debug information.

Parameter	Description
global_object_db	DDS global object database.
peer <A.B.C.D>	Peer for the global object database.
rkey <rkey-id>	Replication key for the global object database.
peerv6 <X:X:X:X::X>	Set peer ipv6 address.
message-stats	Message statistics.
peers	Remote peers.
replication	Object replication.
rkey <rkey-id>	Replication keys
stats	Statistics of the DDS log

Related Commands

  ap-table
  certificates
  counters
  dot1x-counters
  eap-frag-mtu
  machine-auth-cache
  supplicant-info
  watermark
  wired-ap-table
```

Description

Shows the 802.1X related configurations.

Parameter	Description
ap-hash-table	Shows dot1x ap hash table.
ap-table	Shows 802.1X AP table.
certificates	Shows 802.1x certificate usage.
counters	Shows 802.1X counters.
dot1x-counters	Shows 802.1X counters.
eap-frag-mtu	Shows IP MTU for EAP fragmentation.
machine-auth-cache	Shows machine authentication cache.
supplicant-info	Shows details about supplicant(s).
watermark	Shows active and pending queue.
wired-ap-table	Shows 802.1X wired AP table.

Related Commands

Num APs: 5
```

The output of this command includes the following parameters:

Parameter	Description
MAC	The MAC address of the AP
IP	The IP address of the AP
Essid	The AP's ESSID
Type	Device type
AP name	Name of the AP
Vlan	Number of VLANs associated with the specified AP
Enc	AP's encryption method

Parameter	Description
Stations	Number of stations associated with the specified AP
Forwarding Mode	Forwarding mode used by the specified AP
Profile	AP profile
Acl	Number of ACLs this AP belongs to

EAP Failures sent	Number of EAP failures sent.

Parameter	Description
Station failed to respond	Number of times the station failed to respond.
Station NAKs	Number of station negative-acknowledgement characters.
Radius pkts to the server	Number of RADIUS packets set to the server.
Radius pkts from the server	Number of RADIUS packets sent from the server.
Server failed to respond	Number of times the server failed to respond.
Server rejects	Number of times a connection was rejected by the server.
WPA/WPA2-Key Message1	Number of WPA message-1s sent
WPA/WPA2-Key Message2	Number of WPA message-2s sent.
WPA/WPA2-Key Message3	Number of WPA message-3s sent.
WPA/WPA2-Key Message4	Number of WPA message-4s sent.
WPA-GKey Message1	Number of WPA group message-1s sent.
WPA-GKey Message2	Number of WPA group message-2s sent.
ID of the last EAP request	The ID of the last EAP request.
Length of the last EAP request	The length of the last EAP request.
ID of the last EAP response	The ID of the last EAP response.
Length of the last EAP response	The length of the last EAP response.
ID of the last radius request	The ID of the last RADIUS request.
Length of the last radius request	The length of the last RADIUS request.
ID of the last radius response	The ID of the last RADIUS response.
Length of the last radius response	The length of the last RADIUS response.

show dot1x supplicant-info list-all

```
show dot1x supplicant-info list all
```

Description

Shows all 802.1X supplicants.

Syntax

No parameters.

Example

Issue this command to display all 802.1X supplicants as well as additional relevant information.

```
802.1X User Information
-----
      MAC           Name      Auth  AP-MAC           Enc-Key/Type
      Auth-Mode     EAP-Type Remote
-----
00:15:00:26:f8:f5  user1    Yes  00:0b:86:8b:68:68  * * * * * */WPA2-
AES Explicit Mode  EAP-PEAP  No
Station Entries: 1
```

The output of this command includes the following parameters:

Parameter	Description
MAC	Supplicant MAC address
Name	Supplicant name
Auth	Shows if the supplicant authenticated successfully
AP-MAC	AP MAC address
Enc-Key/Type	Enc-Key: Supplicant's encryption key Type: Encryption type used by the supplicant
Auth-Mode	Authentication mode
EAP-Type	EAP type
Remote	Is the supplicant remote

show dot1x supplicant-info pmkid

```
show dot1x supplicant-info pmkid <supplicant-mac>
```

Description

Shows the PMKIDs of the various stations on the controller.

Syntax

No parameters.

Example

Issue this command to display the PMKIDs of the various stations on the controller.

```
PMKID Table
-----
Mac                Name                AP                PMKID
---                -

show dot1x-transactions-monitor

```
show dot1x-transactions-monitor stats
```

Description

This command displays the rate statistics, per second, for a 802.1X user. The command output is displayed only when the interval and duration is set in the `dot1x-transactions-monitor set` command, and the start action is executed in the `dot1x-transactions-monitor` command.

Parameter	Description
stats	<p>Displays the 802.1X rate statistics, per second. The output of the command displays Interval, Success, Failure, Dot1x-Station-Up, EAP-Request-Sent, EAP-Response-Received, Radius-Request-Sent, and Radius-Response-Received per second in each interval.</p> <p>NOTE: To stop the running statistics, execute the stop parameter under the <code>dot1x-transactions-monitor</code> command.</p>

Example

The output of the `show dot1x-transactions-monitor` command displays the rate statistics for the 802.1X users:

```
(host) [mynode] #show dot1x-transactions-monitor stats
802.1x Rate Statistics (All numbers are per second in each interval)
-----
Interval Success Failure Dot1x-Station-Up EAP-Request-Sent EAP-Response-
Received Radius-Request-Sent Radius-Response-Received
-----
1 0.0889 0.0000 0.0889 1.2444 1.1556 0.9778 0.9778
2 0.0444 0.0000 0.0444 0.6222 0.5778 0.4889 0.4889
3 0.0444 0.0000 0.0444 0.6222 0.5778 0.4889 0.4889
4 0.0444 0.0000 0.0444 0.6222 0.5778 0.4889 0.4889
5 0.2000 0.0000 0.2000 2.8000 2.6000 2.2000 2.2000
```

Related Commands

Command	Description
<u>dot1x-transactions-monitor</u>	Starts or stops the display of the rate statistics using the <code>show dot1x-transactions-monitor</code> command.
<u>dot1x-transactions-monitor set</u>	Sets the rate statistics interval duration and the total duration of a 802.1X transaction.

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

show dpi

```
show dpi
application
  name
  all
  category <name>
  custom-app <name>
global-bandwidth-contract
  all
  category <name>
  custom-app <name>
custom-app
  all
  string
```

Description

Shows applications and application categories that are configured for DPI. It also shows DPI global bandwidth contracts by application or application category.

Syntax

Parameter	Description
name	Name of the application.
all	Shows all applications.
category <name>	Shows all applications within a category.
custom-app <name>	Shows all custom applications.
global-bandwidth-contract	Shows the DPI global bandwidth contracts.
all	Shows all bandwidth contracts.
app <name>	Shows bandwidth contracts by application name.
appcategory <name>	Shows bandwidth contracts by application category name.
custom-app	Show custom applications.
all	Show all applications.
string	Name of the application to show.

Example

The output of the following command shows custom applications by name, ID, application category, and default ports that are configured for DPI.

```
(host) (config) #show dpi application all

show esi

Syntax

```
groups [{group-name <groupname>|{ping-name <ping-name>}}]  
parser domains|rules|stats  
ping [ping-name <ping-name>]  
servers [{group-name <groupname>|{server-name <server-name>}}]
```

Description

Displays ESI group, parser, ping health check settings, and configuration information for ESI servers.

Parameter	Description
<u>groups</u> group-name ping-name	Shows ESI group information.
<u>parser</u> domains rules stats	Shows ESI parser information.
<u>ping</u> ping-name	Shows settings for ESI ping health check attributes.
<u>servers</u> server-name	Show configuration information for ESI servers.

show esi groups

```
show esi groups [{group-name <groupname>|{ping-name <ping-name>}]
```

Description

Show ESI group information. The ESI parser is a mechanism for interpreting syslog messages from third party appliances such as anti-virus gateways. Use this command to view configured ESI server groups.

Parameter	Description
group-name <groupname>	View the facility used when logging messages into the remote syslog server.
ping-name <ping-name>	Enter the name of a set of ping values to how the names of ESI groups using that set of ping attributes. Define a set of ESI ping values using the command esi ping .

Example

This example below displays the name of each configured ESI group, including its ping definitions and ESI server.

```
(host) #show esi groups

ESI Group Table
-----
Name          Tunnel ID  Ping      Flags  Servers
----          -
anything      0x1042    pingset_1 C       0
cupertino     0x1043    -         C       0
Flags:
  C:Datapath Download complete
```

show esi parser

```
show esi parser domains|rules|stats
```

Description

Shows ESI parser information. The ESI parser is a generic syslog parser on the controller that accepts syslog messages from external third-party appliances such as anti-virus gateways, content filters, and IDS. It processes syslog messages according to user-defined rules and takes configurable actions on the corresponding system users. ESI servers are configured into domains to which ESI syslog parser rules are applied.

Parameter	Description
domains	Show ESI parser domain information.
rules	Show ESI parser rule information.
stats	Show ESI parser rule stats.

Example

Use the `show esi parser domains` command to show ESI parser domain information.

The ESI Parser Domain table in the example below shows that the controller has two ESI domains and two ESI servers.

```
(host) [mynode] (config) #show esi parser domains

ESI Parser Domain Table
-----
Domain          ESI Servers   Peer controllers
-----
corp_domain     172.21.5.50   10.3.132.14
remote_domain   192.84.66.30

Total number of servers configured: 2
```

show esi ping

```
show esi ping [ping-name <ping-name>]
```

Description

Show settings for ESI ping health check attributes.

Parameter	Description
ping-name <ping-name>	Include the optional ping-name <ping-name> parameters to display settings for one specified set of ping settings.

Example

This example below shows that the controller has three defined sets of ping attributes.

```
(host) #show esi groups

ESI Ping Table
-----
Name          Frequency (sec)  Timeout (sec)  Retry Count  ID  Num Groups
-----
ping_att1          5                5                2            2    2
ESIPing           50000            5                2            2    2
ESIPing2           50000            5                2            2    2
```

The output of this command includes the following information:

Column	Description
Name	Name of a group of ping settings.
frequency	Specifies the ping frequency in seconds.
timeout	Specifies the ping timeout in seconds.
retry-count	Specifies the ping retry count
ID	ID number assigned to the ping attributes when that set of attributes was defined.
Num Groups	Number of ESI groups to which this set of ping attributes is assigned.

Related Commands

Platforms	Licensing
esi ping	This command specifies the ESI ping health check configuration.

show esi servers

```
show esi servers [{group-name <groupname>|{server-name <server-name>}]
```

Description

Show configuration information for ESI servers. By default, this command displays configuration settings for all ESI servers. You can include the name of an ESI group to view servers assigned to just that group, or specify a server name to view information for that server only.

Parameter	Description
server-name <server-name>	Specify an ESI server name to view configuration information for just that server.

Example

This example below displays configuration details for the ESI server name **forti_1**.

```
(host) #show esi servers server-name forti_1

ESI Server Table
-----
Name      Trusted IP      Untrusted IP    Trusted Port  Untrusted Port  Group  Mode
  NAT Port  ID
-----  -
-----  --
forti_1  10.168.173.2   10.168.171.3   -/-/-        -/-/-          default
route 0      4

Flags
-----
U

Flags:
C :Datapath Download complete
U :Server Up
D :Server Down
PT:Trusted Ping response outstanding
PU:Untrusted Ping response outstanding
HT:Health Check Trusted IP
HU:Health Check Untrusted IP
FT:Trusted Ping failed
FU:Untrusted Ping failed
```

The output of this command includes the following information:

Column	Description
Name	Name of the ESI server.
Trusted IP	Displays the server IP address on the trusted network. As an option, you can also enable a health check on the specified address
Untrusted IP	Displays the server IP address on the untrusted network. As an option, you can also enable a health check on the specified address
Trusted Port	Shows the slot and port connected to the trusted side of the ESI server in the format <slot>/<module>/<port>.
Untrusted Port	Shows the slot and port connected to the untrusted side of the ESI server in the format <slot>/<module>/<port>.
Group	Name of the ESI group to which this server is assigned. If the server has not yet been assigned to a group, this column will be blank.
Mode	Specifies the ESI server mode of operation: bridge, nat, or route
Nat Port	Displays the NAT destination TCP or UDP port.
ID	ID number assigned to the server when it was first defined.
Flags	This data column displays any flags associated with this server. The flag key appears below the ESI Server Table.

```

The output of this command includes the following information:

Column	Description
IP Address	IP address of the managed device.
Name	Name of the managed device or switch.
Type	Type of device.

Column	Description
Version	Version of the ArubaOS software running on the device.
Profile	Denotes the EST profile configured on the device.
Status	The status of the EST profile.
Expiry Time	Denotes the date and time of the expiry of the certificate enrollment.
Expiry Status	Denotes the current expiry status such as Certificate is Expiring Soon, Expired, or Not Expired.

Command History

Version	Description
ArubaOS 8.8.0.0	Added a new subparameter, <code>CSR attribute Config</code> , in the output table.
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show est profile

```
show est profile {default|<profile-name>}
```

Description

Displays the information of the activated EST profiles on the device. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
<profile-name>	Name of this instance of the profile.

Example

The output of this command shows the default EST profile of a single managed device:

```
(host) [mynode] # show est profile default
EST Profile "default"
-----
Parameter                Value
-----
Server Host                N/A
Server Port                443
Challenge password        N/A
Arbitrary label            N/A
Server's CA Cert Name     N/A
Organizational Unit Name  N/A
Arbitrary enrollment label /ca:7
Arbitrary reenrollment label /ca:7
Username                   N/A
Password                   N/A
```

Related Commands

Platforms	Licensing
est	This command configures an EST profile on the controller. This configuration is then pushed to the AP on successful enrollment.
est-activate	This command is used to activate an existing EST profile on the controller or the AP.

show est status

```
show est status [all]
```

Description

Displays the information of the activated EST profiles along with the current status of the EST information on the device.

Parameter	Description
all	Displays the activated EST profiles and the current status of the EST related information of the all switches.

Example

- `show est status`—Use this command to view the current status of the EST related information on the device.
- `show est status all`—Use this command to view the current status of the EST related information of all the switches.

The output of this command shows the current EST status of a single managed device:

```
(host) [mynode] # show est status
EST STATUS
-----
Profile Name       : ssetty26_new
Server Host       : 10.20.21.26
Server Port       : 8443
Enrollment status : Re-enrolled
Arbitrary label enrollment : /ca:7
Arbitrary label reenrollment : /ca:7
Expiry status     : EXPIRING SOON
Valid from        : 2017-08-01 06:02:30
Valid till        : 2017-08-02 06:02:30
Re-enrollment due : 2017-08-02 00:02:30
```

The output of this command shows the current EST status of all the switches:

```
(host) [mynode] # show est status all
EST Status for All Switches
-----
IP Address   Name           Type      Version      Profile
Status       Expiry time    Expiry status
-----

show fault

```
show fault [history]
```

Description

Display a list of faults, which are any problematic conditions of the ArubaOS software or hardware.

Syntax

Parameter	Description
history	Include this parameter to display a history of faults cleared by the managed device or the operator.

Usage Guidelines

A managed device can maintain a list of up to 100 faults. Once 100 faults have been logged, any faults arising after that are dropped. The managed device maintains a history of the last 100 faults that have cleared. Every time a new fault clears clear, the oldest fault in the fault history is purged from the list.

Example

This example below shows all active faults the managed device, including the time the fault occurred, the fault ID number, and a description of the problem.

```
(host) [mynode] (config) #show fault

show firewall

```
show firewall [debug-route][dns-names]
```

Description

Display a list of global firewall policies and policy details.

Syntax

Parameter	Description
debug-route	Show global route debug settings, including the route protocol (IPv4/IPv6) and IP address.
dns-names	Display a list of DNS names and IP addresses used in firewall commands.

Examples

Include the optional `dns-names` parameter to list the DNS names used in firewall policies currently configured on the controller.

```
(host) [mynode] #show firewall dns-names
FW DNS names
-----
Name                Id  InUse  List
-----

Drop Larger than IPSEC MTU DF frame Enabled
Track Spoofs in Data Path           Disabled
Rate limit CP IKE traffic            Disabled
High Water Mark Percent for Outstanding Buffers Disabled
Monitoring Frequency for Outstanding Buffers Disabled
DPI classification cache             Enabled
Drop all ip spoofs                  Disabled
Prohibit RC Update                  Disabled
Enable session-spread               Disabled

```

The output of this command includes the following information:

Parameter	Description
Enforce TCP handshake before allowing data	If enabled, this feature prevents data from passing between two clients until the three-way TCP handshake has been performed. This option should be disabled when you have mobile clients on the network as enabling this option will cause mobility to fail. You can enable this option if there are no mobile clients on the network.
Prohibit RST replay attack	If enabled, this setting closes a TCP connection in both directions if a TCP RST is received from either direction.
Deny all IP Fragments	If enabled, all IP fragments are dropped.

Parameter	Description
Prohibit IP Spoofing	When this option is enabled, source and destination IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.
Monitor ping attack	If enabled, the controller monitors the number of ICMP pings per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack.
Monitor TCP SYN attack	If enabled, the controller monitors the number of TCP SYN messages per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack.
Monitor IP sessions attack	If enabled, the controller monitors the number of TCP sessions requests per second. If this value exceeds the maximum configured rate, the controller will register a denial of service attack sessions.
Deny inter user bridging	If enabled this setting prevents the forwarding of Layer-2 traffic between wired or wireless users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic.
Enable GRE Inner Frame Fragmentation	If enabled, the inner GRE frames are fragmented, when packet length is greater than tunnel MTU.
Drop Larger than GRE MTU DF frame, send ICMP Err	If enabled, IP packets with DF bit set are dropped when packet length is greater than GRE tunnel MTU and an ICMP error message is sent.
Drop Larger than GRE MTU DF frame	If enabled, IP packets with DF bit set are dropped when packet length is greater than GRE tunnel MTU and an ICMP error message is not sent.

Parameter	Description
Drop Larger than GRE MTU frame, send ICMP Err	If enabled, IP packets are dropped when packet length is greater than GRE tunnel MTU and an ICMP error message is sent.
Drop Larger than GRE MTU frame	If enabled, IP packets are dropped when packet length is greater than GRE tunnel MTU and an ICMP error message is not sent.
Log all received ICMP errors	Shows if the controller will log received ICMP errors.
Per-packet logging	If active, and logging is enabled for the corresponding session rule, this feature logs every packet.
Blacklist/Denylist Grat ARP attack client	If enabled, blacklist/denylistclients exceeding the Gratuitous ARP attack rate.
Allow tri-session with DNAT	Shows if the controller allows three-way session when performing destination NAT.
Disable FTP server	If active, this feature disables the FTP server on the controller.
Blacklist/Denylist ARP attack client	If enabled, blacklist/denylistclients exceeding the ARP attack rate.
Monitor ARP attack	Shows the status of the ARP attack monitor.
Monitor Gratuitous ARP attack	Shows the status of the Gratuitous ARP attack monitor.
GRE call id processing	If active the controller creates a unique state for each PPTP tunnel.
Session Idle Timeout	Shows if a session idle timeout interval has been defined.
WMM content enforcement	If traffic to or from the user is inconsistent with the associated QoS policy for voice, this feature reclassifies traffic to best effort and data path counters are incremented.

Parameter	Description
Session VOIP Timeout	If enabled, a idle session timeout is defined for sessions that are marked as voice sessions.
Trust packet QoS	Displays if the RTP traffic is passed without changing the DSCP value.
Only allow local subnets in user table	If enabled, the controller only adds IP addresses which belong to a local subnet to the user table.
Monitor/police CP attacks	If enabled, the controller monitors a misbehaving user's inbound traffic rate. If this rate is exceeded, the controller can register a denial of service attack.
Rate limit CP untrusted ucast traffic	Shows the inbound traffic rate
Rate limit CP untrusted mcast traffic	Displays the untrusted multicast traffic rate limit.
Rate limit CP trusted ucast traffic	Displays the trusted unicast traffic rate limit.
Rate limit CP trusted mcast traffic	Displays the trusted multicast traffic rate limit.
Rate limit CP route traffic	Displays the traffic rate limit for traffic that needs generated ARP requests.
Rate limit CP session mirror traffic	Displays the traffic rate limit for session mirrored traffic forwarded to the controller.
Rate limit CP auth process traffic	Displays the traffic rate limit for traffic forwarded to the authentication process.
Rate limit CP vrrp traffic	Displays the rate limit of VRRP traffic routed to the control plane.
Rate limit CP ARP traffic	Displays the ARP traffic rate limit in packets per second.
Rate limit CP L2 protocol/other traffic	Displays the traffic rate limit for L2 protocol and L2 special handling traffic.

Parameter	Description
Rate limit CP IP Error pkts	Displays the rate limit error IP in packets per-second.
Rate limit CP IKE traffic	Displays the traffic rate limit from IKE to CP, in packets per second.
Deny inter user traffic	If enabled, this setting disables traffic between all untrusted users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic.
Prohibit ARP Spoofing	When this option is enabled, possible arp spoofing attacks are logged and an SNMP trap is sent.
Enforce bw contracts for broadcast traffic	If enabled, bw contracts are applied ot local subnet broadcast traffic.
Multicast automatic shaping	If enabled, enables multicast optimization and provides excellent streaming quality regardless of the amount of VLANs or IP IGMP groups that are used.
Stall Detection	If enabled, triggers datapath crash on stall detection. Applies to the to 7200 Seriescontrollers only.
Enforce TCP Sequence numbers	If enabled, prevents data from passing between two clients until the three-way TCP handshake has been performed.
AMSDU Rx	AMSDU packets are dropped if this option is enabled.
Jumbo Frames	If enabled, supports up to 9216 bytes of payload on the controller.
Session-tunnel FIB	Enables session tunnel based forwarding.

Parameter	Description
Prevent DHCP Exhaustion	If enabled, this option checks for DHCP client hardware address against the packet source MAC address. This command checks the frame's source-MAC against the DHCPv4 client hardware address and drops the packet if it does not match. This feature prevents a client from submitting multiple DHCP requests with different hardware addresses, thereby preventing DHCP pool depletion.
Deny Source Routing	If enabled, forwarding of IP frames with source routing with the source routing options set is disallowed.
Immediate Freeback	If enabled, immediately frees buffers on 7200 Series controllers. Do not enable this option unless instructed to do so by a technical support representative.
DPI Classification	If enabled, performs deep packet inspection.
Track Spoofs in Data Path	If enabled, checks if there is a spoof in datapath.
Web Content Classification	If enabled, allows web content classification for all HTTP traffic. Default: disabled
Web Content Cache Miss Drop	If enabled, allows the controller to drop any packets that do not match any web content category or reputation levels in the controller's internal web content cache. Default: disabled
Optimize Duplicate Address Detection frames	Reduce flooding of IPv4 Gratuitous ARPs/IPv6 Duplicate Address Detection frames onto wireless clients. Default: enabled

Related Commands

All platforms	Base operating system.	Config mode on Mobility Conductor.

show firewall-cp

```
show firewall-cp
  internal
```

Description

Displays the Control Path firewall policies on the controller.

Example

The output of this command shows the CP firewall policies.

```
(host) [mynode] #show firewall-cp

CP firewall policies
-----
IP Version  Source IP      Source Mask  Protocol  Start Port  End Port
Permit/Deny hits  contract
-----
-----
ipv4        any            0            6         21          21         Permit
0          test
ipv4        10.10.10.10   2.2.2.2     6         8           9         Permit

ipv4        2:2:2:2::2    0            1         1           2         Permit
0
```

Related Commands

Command	Description
firewall	This command configures firewall options on the controller.
firewall cp-bandwidth-contract	This command configures bandwidth contract traffic rate limits to prevent denial of service attacks.

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show firewall-visibility

```
show firewall-visibility {aggregate-sessions-central|debug|status}
```

Description

This command displays the policy enforcement firewall visibility process state and status information.

Parameter	Description
aggregate-sessions-central	Display firewall visibility aggregate sessions table for Aruba Central.
debug	Displays process state information for debugging firewall visibility.
status	Displays the status of firewall visibility as enabled or disabled.

Example

The following command displays the status of firewall visibility.

```
(host) [mynode] #show firewall-visibility status
enabled
```

The following command displays the status of firewall visibility sessions and their grouping based on the BSSID.

```
(host) [mynode] #show firewall-visibility status
Firewall Visibility Status:
enabled
Sort by Bssid Status:
  sorting enabled:  Enabled
  sort by bssid needed:  Enabled
```

Related Commands

Command	Description
firewall	This command configures firewall options on the controller.
firewall cp	This command creates whitelist/allowlist session ACLs
firewall cp-bandwidth-contract	This command configures bandwidth contract traffic rate limits to prevent denial of service attacks.

Command History

Release	Modification
ArubaOS 8.10.0.0	The show firewall-visibility status command output includes the Sort by Bssid Status parameter.
ArubaOS 8.0.0.0	Command introduced.

All platforms	PEFNG license.	Config or Enable mode on Mobility Conductor.

show flush-r1-on-new-r0

```
ap·flush-r1-on-new-r0 {enable|disable}
```

Description

Use this command to view the status of flushing r1 keys on new r0.

Syntax

No parameters.

Example

The following example displays the status of flushing r1 keys on new r0:

```
(host) [mynode] (config) #show flush-r1-on-new-r0
Fast Roaming flush-r1-on-new-r0:enable
```

Related Commands

Command	Description
ap flush-r1-on-new-r0	This command enables or disables flushing of R1 keys, when R0 is updated for d-tunnel or bridge mode.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode or Config mode.

show gap-debug

show gap-debug

Description

Displays the troubleshooting information for the global AP database.

Usage Guidelines

Use this command to identify any issues with the global AP database. This command displays the troubleshooting information for the global AP database.

Example

The following is a sample output of this command:

```
(host) [mynode] (6000-202) #show gap-debug

```

The output of this command includes the following information:

Parameter	Description
IP	The IP address of the managed device

Parameter	Description
Master/Conductor Cookie	The cookie information on Mobility Conductor that is used to communicate with the LMS.
Master/Conductor Seq	The sequence number used by Mobility Conductor to sync up with the LMS. This tracks the number of times Mobility Conductor has communicated with the LMS.
LMS Cookies	The cookie information on the LMS that is used to communicate with Mobility Conductor.
LMS Seq	The sequence number used by the LMS to sync up with Mobility Conductor. This tracks the number of times the LMS has communicated with Mobility Conductor.
Activity	The time at which the last activity happened on the LMS.
Status	Indicates if the status of the LMS is up or down.
Msg in Prog	Indicates if an active communication is happening between the LMS and Mobility Conductor. It can be Yes or No. If it is yes, then the Msg Len and Attempt fields are set.
Msg Len	The length of the message that Mobility Conductor is syncing with the LMS.
Attempts	Number of times Mobility Conductor has attempted to sync with the LMS.
Last Reset Reason	Indicates the reason for last reset.

Related Commands

Command	Description
<code>ap gap-db</code>	Resynchronize an AP status on a managed device and Mobility Conductor.

Command History

Release	Modification

show gateway health-check

show gateway health-check

Description

Display the current status of the gateway health-check feature.

Syntax

No parameters.

Usage Guidelines

The gateway health check feature can only be enabled by Aruba Technical Support.

Example

This example below shows that the gateway health-check feature has not been enabled on the managed device.

```
(host) [mynode] (config) #show gateway health-check
Gateway health check not enabled
```

Related Commands

Command	Description
gateway health-check	Disable the gateway health check

show global-user-table

Syntax

```
show global-user-table count|list
```

Description

This command displays a count of global user based on the specified criteria or displays the list of users matching the given criteria.

Parameter	Description
count	Show the number of users matching the given criteria
ap-name	Count users matching the specified AP name
authentication-method	Count users matching the specified authentication method
bssid	Count users matching the specified BSSID
current-switch	Match IP address of the switch where the user is currently associated
ssid	Count users matching the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.
phy-type	Count users matching the specified Phy type
role	Count users matching the specified role
age	Count users matching the specified age
list	Show users matching the given criteria
ap-name	Lists users matching the specified AP name
authentication-method	Lists the users matching the specified authentication method
bssid	Lists the users matching the specified BSSID
current-switch	Match IP address of the switch where the user is currently associated
current-switch-v6	Match IPv6 address of the switch where the user is currently associated

Parameter	Description
devtype	Lists the users matching device type
ssid	Lists the users matching the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.
ip	Match IP address
ipv6	Match IPv6 address
mac-addr	Match MAC address
name	Match name
not	Show users that do not satisfy the given criteria
or	Show users that satisfy any of the given condition
phy-type	Match PHY type
role	Match role
rows	Show certain rows
start	Show user table starting from the specific row

Examples

```
(host) [mynode] #show global-user-table list

Global Users
-----
      IP          MAC          Name      Current switch  Role  Auth  AP name
Roaming  Essid    Bssid  Phy  Profile  Type  User Type

show gsm

```
show gsm
  application
  channel-matrix
  debug
  lookup
```

Description

This command displays the list of all interfaces. Click the parameter links below to view the corresponding show commands.

Parameter	Description
application	Displays the status of the GSM application, for example, stm, auth, and so on.
channel-matrix	Displays the channels with Publisher and Subscriber Information.
debug	Displays status, event ring channel information, and trace events for channel and assignment related features like cluster, LLDP, tunneled nodes, UCC, and so on.
lookup	Displays status, event ring channel information, and trace events for specific channel and assignment related features like cluster, LLDP, tunneled nodes, UCC, and so on.

Description

This command displays status, event ring channel information, and trace events for channel and assignment related features like cluster, LLDP, tunneled nodes, UCC, and so on.

Parameter	Description
Channel	Channel Name
ag_user	AirGroup User Channel
ale_sta	Analytics and Location Engine Data
all	All GSM Channels
amon_registration	AMON messages Registration Data
ap	AP Channel
application_status	Application Status Data
blacklist/denylist	Blacklist/Denylist Channel
bss	BSS Channel
bucket_map	STA Hash Bucket to UAC map
cac_usage	Call Admission Control Usage Data
cluster	controller Cluster Info
cluster_aac	Cluster AAC Assignment Data
cluster_ap	Cluster AP Data
cluster_bss	Cluster BSS Data
cluster_sta	Cluster STA Data
cluster_tunneled_node	Cluster Tunneled Node Channel.
dds_peer	DDS Peer Info
dev_id_cache	Device Id Cache Channel
device_config	Device Config

Parameter	Description
device_lclist	Device Lclist
dhcpd_via_info	DHCP VIA Channel
ha_info	HA Info Channel
ip_probe	MIP Proxy Info
ip_user	IP User Channel
ipsec_tunnel_info	ipsec_tunnel_info Channel
key_cache	Key Cache Channel
license_keys	License Keys Channel
lldp_chassis_info	LLDP Chassis Info Channel
lldp_info	LLDP Info Channel
mac_user	Layer 2 MAC user Channel
mip_proxy	MIP Proxy Info
mip_tunnel	Mobileip tunnel control information.
named_vlan_info	Named vlans information.
pmk_cache	PMK Cache Channel
port_info	Port Info Channel
radio	Radio Channel
rap_whitelist/rap_allowlist	RAP Whitelist/Allowlist Channel
remote_ip_user	Remote IP User Data
rep_key	Replication Key Channel
sectun	Secured Tunnel Channel
service_ctrl_info	Service Control Info
sta	STA Channel
sys_racl	sys_racl Data
tunneled_node	Tunneled Node Channel.
tunneled_user	Tunneled User Channel.

Parameter	Description
ucc_client	UCC Client Channel
ucc_session	UCC Session Channel
user	User Channel
v4_dhcp_pool	v4 DHCP Pool Info
via_user	VIA VPN users information
vlan_info	VLAN Info Channel
web_cc_info	Web content classification Info Channel
wired_ap	Wired AP Channel
rkey	Replication key
assignment	Current Replication Key assignment
rap_public_ip	Displays the public IP address of the Remote AP cluster configured behind NAT.

Example

The following command checks the status of the tunneled node:

```
(host) [mynode] #show gsm debug channel tunneled_node status
GSM Channel status for Channel:TUNNELED_NODE
CSM:: Key = 0X1BB7, Size = 357612 B
DSM:: Base Key = 0X1BB8, Size = 524288 B Max number of segments = 1 Segments

Description

This command displays status, event ring channel information, and trace events for specific channel and assignment related features like cluster, LLDP, tunneled nodes, UCC, and so on. The optional output modifiers `| begin` , `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

mip_tunnel	Mobileip tunnel control information.
named_vlan_info	Named vlans information.
ofa_port	OpenFlow Port Channel
pmk_cache	PMK Cache Channel
port_info	Port Info Channel
radio	Radio Channel
rap_whitelist/rap_allowlist	RAP Whitelist/AllowlistChannel
rep_key	Replication Key Channel
sectun	Secured Tunnel Channel
service_ctrl_info	Service Control Info
split_tunnel	Split Tunnel
sta	STA Channel
sys_racl	sys_racl Data
tunneled_node	Tunneled Node Channel.

Parameter	Description
tunneled_user	Tunneled User Channel.
ucc_client	UCC Client Channel
ucc_session	UCC Session Channel
user	User Channel
vlan_info	VLAN Info Channel
vrrp_info	Virtual Router Redundancy Protocol Information
web_cc_info	Web content classification Info Channel
wired_ap	Wired AP Channel

Example

The following example displays the GSM channel report for a radio with BSSID 48:4a:e9:7c:8c:d0:

```
(host) [mynode] #show gsm lookup channel radio key radio_bssid
48:4a:e9:7c:8c:d0

Object details as follows:
      state      :: ACTV
      rep_key     :: 1
      v_repkey    :: 3
      radio_bssid :: 48:4a:e9:7c:8c:d0
      ap_name     :: 48:4a:e9:cf:c8:cc
      ap_ip_address :: fd8d:3da:cf00:666:828d:b7ff:fec0:fc
```

show guest-access-email

show guest-access-email

Description

This command shows a guest access email profile configuration. The guest access email process sends email to either the guest or the sponsor whenever a guest user account is created or when the Guest Provisioning user manually sends email from the GPP.

Syntax

No parameters.

Usage Guidelines

Issue this command to show the current guest access email profile parameters. The **Parameter** and **Value** columns show the configured SMTP server and SMTP ports. that process guest email.

```
(host) [mynode] (config) #show guest-access-email

Guest-access Email Profile
-----
Parameter      Value
-----
SMTP Server    10.1.1.4
SMTP Port      25
```

show ha ap

```
show ha ap
  information {ip-addr <ip-addr>|ip6-addr <ip6-addr>}
  table
```

Description

This command displays information about APs using the High-Availability (HA) features. The HA features work across Layer-3 networks, so there is no need for a direct Layer-2 connection between a High-Availability group when the AP first connects to its active. The active provides the IP address of a standby and the AP attempts to establish a tunnel to the standby. If an AP fails to connect to the first standby, then the active will select a new standby for that AP, and the AP will then attempt to connect to that standby .

An AP will failover to its backup if it fails to contact its active through regular heartbeats and keepalive messages, or if the user manually triggers a failover using the WebUI or CLI.

Parameter	Description
<pre>information ip-addr <ip-addr> ip6-addr <ip6-addr></pre>	Issue this command under the supervision of Aruba support to troubleshoot the HA feature.
<pre>table</pre>	Display the HA AP table to view information about APs configured to use the HA feature.

Examples

The following command displays the HA table for the HA group **default**:

```
(host) [mynode] (config) #show ha ap table
HA AP Table
-----
AP          IP-Address   MAC-Address   AP-flags  HA-flags
--          -
ard         10.3.31.245  6c:f3:7f:c6:72:c0  LU
arr         10.3.31.222  d8:c7:c8:c0:02:7c  LU
kalap105-2  10.3.31.253  00:24:6c:c0:22:6b  LU          S
Total Num APs::3
Active APs::2
Standby APs::1
AP Flags: R=RAP; S=Standby; s=Bridge Split VAP L=Licensed; M=Mesh, U=Up
HA Flags: S=Standby, C=Standby connected, L=LMS, F=Sent Failover Request to
AP,
H=AP flagged for Inter Controller Heartbeat
```

show ha group

```
show ha
  group-membership
  group-profile [<profile>]}
```

Description

This command displays HA profile settings and shows the HA group to which the managed device is currently assigned. The HA feature supports redundancy models with an active managed device pair, or an active or standby deployment model with one backup managed device supporting one or more active managed devices. Each of these clusters of active and backup managed devices comprises a HA group. Note that all active and backup managed devices within a single HA group must be deployed in a single Mobility Conductor - managed device topology. The HA feature works across Layer-3 networks, so there is no need for a direct Layer-2 connection between managed devices in a HA group.

Parameter	Description
group-membership <profile>	Name of the HA group to which the managed device should be a member.
group-profile [<profile>]	Display a list of all HA groups, or include the optional <profile> parameter to display configuration settings for the specified profile.

Examples

The following command shows that the managed device from which the command was issued is a member of the HA group ha-group2:

```
(host) [mynode] (config) #show ha-group-member
Member of HA group :ha-group2
```

The following example shows that the managed device has two configured HA group profiles. The **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column:

```
HA group information List
-----
Name      Profile Status
----      -
default
new
Total: 2
```

show ha heartbeat counters

```
show ha heartbeat counters
```

Description

This command displays statistics for the HA extended managed device capacity feature. The HA inter-managed device heartbeat feature allows for faster AP failover from an active managed device to a standby managed device, especially in situations where the active managed device reboots or loses connectivity to the network.

The inter-managed device heartbeat feature works independently from the AP mechanism that sends heartbeats from the AP to the managed device. If enabled, the inter-managed device heartbeat feature supersedes the AP's heartbeat to its managed device. As a result, if a standby managed device detects missed inter-managed device heartbeats from the active managed device, it triggers its standby APs to failover to the standby managed device, *even if those APs have not detected any missed heartbeats between the APs and their active managed device*. Use this feature with caution in deployments where the active and standby managed device are separated over high-latency WAN links.

This feature is disabled by default. It can be used in conjunction with the HA state synchronization feature only in topologies that use a single active and standby managed device, or a pair of dual-mode active managed devices that act as a standby managed device for each other. HA inter-managed device heartbeats can be enabled and configured in the HA group profile using the WebUI or CLI.

Examples

The following command displays HA heartbeat statistics for the HA group **default**:

```
(host) [mynode] (HA group information "default") #show ha heartbeat counters

Heartbeat stats
-----
Controller IP   Active Reference Count      Total Heartbeat Sent      Total
Heartbeat Received
-----
-----
172.14.0.2      1                          101                        101

Last Missed Heartbeat (Count) Time
-----
0
```

The output of this command includes the following parameters:

Parameter	Description
IP	IP address of the managed device from which this command was issued.
Active Reference Count	Number of APs that are using that standby managed device as their active managed device.
Total HeartBeat Sent	Total number of heartbeats sent by the managed device.
Total Heartbeat REceived	Total number of heartbeats received by the managed device.
Last Missed Heartbeat(count) time	Timestamp showing when the last heartbeat sent was not received, as well as the number of heartbeats that failed to be sent.

show ha oversubscription statistics

show ha oversubscription statistics

Description

This command displays statistics for the HA extended managed device capacity feature. A managed device acting as a standby managed device can oversubscribe to standby APs by up to four times that managed device's rated AP capacity, as long as the tunnels consumed the standby APs do not exceed the maximum tunnel capacity for that standby managed device.

Feature Requirements

All managed devices using this feature must be deployed in a master/ conductor -local topology where centralized licensing is enabled on the active and standby managed device. If centralized licensing is disabled, the standby AP oversubscription feature is also disabled. Standby managed device oversubscription and the HA state synchronization features are mutually incompatible and cannot be enabled simultaneously. If your deployment uses the state synchronization feature, you must disable it before you enable standby managed device oversubscription.

Standby Managed Devices Capacity

The following table describes the AP oversubscription capacity maximum supported tunnels and for managed devices that support this feature:

controller Model	Standby AP Capacity	Maximum Tunnels Supported
7210	4x rated AP capacity	16384 tunnels
7220	4x rated AP capacity	32768 tunnels
7240	4x rated AP capacity	65536 tunnels

To determine the number of standby tunnels consumed by APs on each active managed device, multiply the number of APs on the active managed device by the number of BSSIDs per AP. As an example, consider a deployment with four active 7210 managed devices that each have 512 APs with 8 BSSIDs. The APs on each active managed device consume (512 * 8) tunnels, for a combined total of 16,384 tunnels. A single 7210 managed device using the standby managed device oversubscription feature can act as the standby managed device for all four active managed devices in this example, because this topology is within the 4x rated AP capacity limit and maximum tunnel limit for the 7210 managed device model.

If the network administrator later changed all the APs in this deployment to support 10 BSSIDs, each active managed device would use (512 * 10) tunnels, for a combined total of 20,480 tunnels

on the four active managed devices. The tunnels required by the APs on the active managed device would then exceed the maximum tunnel limit for the standby managed device, so the standby managed device can no longer support all APs on the active managed device.

AP Failover

If a standby managed device reaches its AP oversubscription capacity or exceeds its maximum BSSID limit, the standby managed device drops any subsequent standby AP connections. A dropped AP attempts to reconnect to the standby managed device, but after it exceeds the maximum number of request retries, the AP informs the active managed device that it is unable to connect to the standby managed device. The active managed device then prompts the AP to create a standby tunnel to another standby managed device, if one is configured.

If an active managed device fails, the APs on the active managed device fail over to the standby managed device. Once the standby managed device has reached its capacity for active APs, it terminates tunnels to any standby APs that controller can no longer serve. When these APs detect that there is no longer a heartbeat between the AP and the standby managed device, they notify their active managed device that they can no longer connect to the standby. The active managed device then prompts the APs to establish standby tunnels to another standby managed device, if one is configured.

Examples

The following command displays oversubscription statistics for APs and tunnels:

```
(host) [mynode] (config) #show ha oversubscription statistics
Platform oversubscription factor :          4
APs Limits
-----
APs                Number
----             -
Platform Limit     512
Current Active     2
Current Standby    694
Active remaining   0
Standby remaining  1
Maximum allowed Standby 697

BSS Limits
-----
Tunnels           Limits
-----
Maximum BSS tunnels 16384
Average BSS/AP      23
BSS tunnels in use  16360
BSS tunnels available 24
```

The output of this command includes the following parameters:

Parameter	Description
Platform limit	Maximum number of APs supported by the managed device platform.
Current Active	Number of active APs currently associated to the managed device.
Current Standby	Number of APs that are currently using the managed device as a standby managed device.
Active Remaining	Number of APs that can connect to this managed device in Active mode.
Standby Remaining	Number of APs that can connect to this managed device in Standby mode.
Maximum allowed Standby	Maximum number of Standby APs supported by the managed device.
Maximum BSS tunnels	The maximum number of BSS tunnels supported by the managed device.
Average BSS/AP	The average number of BSS tunnels per AP using the managed device as a standby managed device.
BSS tunnels in use	Number of BSS tunnels currently in use by the managed device.
BSS tunnels available	Number of BSS tunnels not currently in use by the managed device.

```

Description

Displays the statistics of an IAP VPN subnet. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
subnet <subnet-name>	Displays specific subnet information for an IAP.

Example

The following command displays details of a subnet:

```
(host) [mynode] (config) #show iap subnet-stats subnet <subnet>
```

Related Commands

Command	Description
hostname	This command changes the hostname of the Mobility Conductor, standby controller, or managed device.
iap trusted-branch-db	This command is used to configure an Instant AP (IAP)-VPN branch as trusted.

Command History

Release	Modification
ArubaOS 8.6.0.17 and 8.7.1.9	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters.	Enable or Configuration mode on managed devices.

show iap subnets-summary

```
show iap subnets-summary
```

Description

Displays the summary of IAP subnet information. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following command displays details of a subnet:

```
(host) [mynode]# show iap subnets-summary
Summary of IAP Branch Subnets
-----
S.No  Subnet Name                MaxBID  BIDs set in Bitmap  BIDs free in
Bitmap Allocated Branches      Down Branches  Reclaimed from Down Branches
-----
-----
1     1.1.1.0-1.1.1.255,1        64       4                   60
    4                        3                   0
2     50.11.0.0-50.11.255.255,5 8192     5                   8187
    5                        4                   0
3     59.59.95.0-59.59.95.100,4 12       2                   10
    2                        2                   0
```

show iap table

```
show iap table
  branch-key <brkey>
  long
  summary
```

Description

Displays the branch details connected to the managed device.

Parameter	Description
branch-key <brkey>	Key for the branch, which is unique to each branch.
long	Displays the branches connected to the managed device in detailed view.
summary	Displays the summary of the IAP table.

Example

The following example shows the details of the branches connected to the managed device:

```
(host) [mynode] (config) #show iap table long

Total No of DOWN Branches   : 4
Total No of Branches        : 8

```

Tunnel End Points

The output of this command includes the following parameters:

Parameter	Description
VC Name	Name of Virtual managed device of the branch.
VC MAC Address	MAC address of the Virtual managed device of the branch.
Status	Current status of the branch (UP or DOWN).
Inner IP	Internal VPN IP of the branch.
Assigned Subnet	Subnet mask assigned to the branch.
Assigned Vlan	VLAN ID assigned to the branch.
VC Branch Name/Key	Key for the branch, which is unique to each branch.
Bid(Subnet Name)	<p>Branch ID (BID) of the subnet.</p> <p>In the example above, the managed device displays bid-per-subnet-per-branch i.e., for "LA" branch, BID "2" for the ip-range "10.15.205.0-10.15.205.250" with client count per branch "5"). If a branch has multiple subnets, it can have multiple BIDs.</p> <p>Branches that are in UP state and do not have a Bid(Subnet Name) means that the IAP is connected to a managed device which did not assign any bid for any subnet. In the above example, "Paris-CB:D3:16" branch is UP and does not have a Bid(Subnet Name) information. This means that either the IAP is connected to a backup managed device or connected to a primary managed device without any distributed L2 or L3 subnets.</p> <p>For more information on bid-per-subnet-per-branch and distributed L2 and L3 subnets, see the <i>DHCP Configuration</i> chapter of the Aruba <i>Instant Access Point 6.2.1.0-3.3 User Guide</i>.</p>
Tunnel End Points	Displays tunnel end points for the branch.

show iap trusted-branch-db

```
show iap trusted-branch-db
```

Description

Displays the details of IAP trusted branch database information.

Examples

The following example shows the details of IAP trusted branch database information:

```
(host) [mynode] (config) #show iap trusted-branch-db

Trusted Branch Validation: Enabled
IAP Trusted Branch Table
-----
Branch MAC
-----
01:01:0e:3e:4c:33
```

The following example shows details of IAP trusted branch database information:

```
(host) #show iap trusted-branch-db

Trusted Branch Validation: Disabled
IAP Trusted Branch Table
-----
Branch MAC
-----
(allow all as trusted branch)
```

The output of this command includes the following parameters:

Parameter	Description
Branch MAC	MAC address of the trusted IAP branch.

Related Commands

  rate-thresholds-profile
  signature-matching-profile
  signature-profile
  unauthorized-device-profile
  wms-general-profile
  wms-local-system-profile
```

Description

This command displays the list of all IDS profiles. Click the parameter links below to view the corresponding show commands.

Parameter	Description
ap-classification-rule	Displays the IDS AP Classification Rule Profile.
ap-rule-matching	Displays the IDS Active AP Rules Profile.
dos-profile	Displays an IDS DoS Profile.
general-profile	Displays an IDS General Profile.
impersonation-profile	Displays an IDS Impersonation Profile.
management-profile	Displays the management event correlation for IDS event traps and sylogs (logs).
profile	Displays all ids profiles or displays a specific profile name.
rap-wml-server-profile	Displays an IDS Rate Thresholds Profile.
rap-wml-table-profile	Displays an IDS Rate Thresholds Profile.
rate-thresholds-profile	Displays an IDS Rate Thresholds Profile.
signature-matching-profile	Displays an IDS Signature Matching Profile.
signature-profile	Displays an IDS Signature Profile.

Parameter	Description
unauthorized-device-profile	Displays an IDS Unauthorized Device Profile.
wms-general-profile	Displays general statistics for the WMS configuration.
wms-local-system-profile	Displays statistics for the WMS Local System Profile settings.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ids ap-classification-rule

id-classification-rule <rule-name>

Description

Displays the IDS AP Classification Rule Profile. Issue this command without the <rule-name> option to view the AP Classification Rule Profile list. Add the rule name option to display values for the rule.

Parameter	Description
<rule-name>	Enter the AP classification rule profile name.

Example

The following example is the show command *without* the rule name option:

```
(host) [mynode] (config) #show ids ap-classification-rule
IDS AP Classification Rule Profile List
-----
Name                References  Profile Status
----                -
exclude-ssid-rule   1
rule1                1
rule2                1
Total:3
```

In the example above, the **Reference** column indicates the number of references to the rule named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

Optionally, you can enter a rule name to view the parameters for that rule. For example:

```
(host) [mynode] (config) #show ids ap-classification-rule rule1
IDS AP Classification Rule Profile "rule1"
-----
Parameter                Value
-----
SSID                      Aruba-ap
Match SSIDs               true
Min SNR value             0
Max SNR value             255
Discovered APs count      2
Check for Min Discovered APs true
Classify To AP Type       suspected-rogue
Confidence level increase 5
```

Related Commands

Command	Description

show ids ap-rule-matching

Description

Displays the IDS Active AP Rules Profile. Issue this command to view the Active AP Rules Profile list.

Example

The following command displays AP Rule names information:

```
(host) [mynode] (config) #show ids ap-rule-matching

IDS Active AP Rules Profile
-----
Parameter      Value
-----
AP Rule name   snr0
AP Rule name   rule1
AP Rule name   rule2
AP Rule name   exclude-ssid-rule
```

In the above example, the rule names in the *Value* column have been activated by the **ids ap-rule-matching** command.

Related Commands

Command	Description

show ids dos-profile

```
show ids dos-profile <profile-name>
```

Description

Shows an IDS DoS Profile. Issue this command without the <profile-name> parameter to display an IDS DoS Profile.

Parameter	Description
<profile-name>	Name of an IDS DoS Profile.

Examples

The following example shows that the controller has four configured DoS Profiles:

```
(host) [mynode] (config) #show ids dos-profile

IDS Denial Of Service Profile List
-----
Name      References Profile Status
-----
default   4
test      0
test1     1
Wizard-test 1
Wizard-test2 1

Total: 5
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The following example displays a partial output for the profile **test1**:

```
(host) [mynode] (config) #show ids dos-profile test1
Parameter                                     Value
-----

WMS Client Monitoring              all

```

The output of this command includes the following parameters:

Parameter	Description
Adhoc AP Max Unseen Timeout	Ageout time in seconds since ad hoc (IBSS) AP was last seen.
Adhoc (IBSS) AP Inactivity Timeout	Ad hoc (IBSS) AP inactivity timeout in number of scans.
AP Inactivity Timeout	Time, in seconds, after which an AP is aged out.
AP Max Unseen Timeout	Ageout time, in seconds, since AP was last seen.
Frame Types for RSSI calculation	Frame types used in AM RSSI calculation.

Parameter	Description
IDS Event Generation on AP	Enable or disable IDS event generation from the AP. Event generation from the AP can be enabled for syslogs, traps, or both. This does not affect generation of IDS correlated events on the switch.
Max Monitored Devices	Maximum number of APs and stations that can be monitored. This number does not include stations that are not associated to any AP. Within this max value, the AP reserves a buffer for stations that are associated locally.
Max Monitored APs	Maximum number of monitored APs. Default value: 0
Max Monitored Stations	Maximum number of monitored stations.
Max Unassociated Stations	Maximum number of unassociated stations.
Min Potential AP Beacon Rate	Minimum beacon rate acceptable from a potential AP, in percentage of the advertised beacon interval.
Min Potential AP Monitor Time	Minimum time, in seconds, a potential AP has to be up before it is classified as a real AP.
Mobility Manager RTLS	Shows if RTLS communication with the configured mobility-manager is enabled or disabled.
Monitored Device Stats Update Interval	Time interval, in seconds, for AP to update the switch with stats for monitored devices. Minimum is 60.
Packet SNR Threshold	The packet Signal to Noise Ratio (SNR) threshold. All packets with SNR below this threshold is dropped from IDS and ARM processing. No packets are dropped if the threshold is set to 0.
Send Adhoc Info to Controller	Enable or disable sending adhoc information to the managed device from the AP.
Signature Quiet Time	After a signature match is detected, the time to wait, in seconds, to resume checking.
STA Inactivity Timeout	Time, in seconds, after which a station is aged out.
STA Max Unseen Timeout	Time, in seconds, after which an AP is aged out.

Parameter	Description
Station RSSI Message Interval	Interval, in seconds, at which the AP delivers station RSSI messages to the management server. The range value is 1-36000. The default value is 1 second.
Station RSSI Message	Enables or disables station RSSI messages. The default value is disabled.
Stats Update Interval	Interval, in seconds, for the AP to update the managed device with statistics. This setting takes effect only if the Aruba Mobility Manager is configured. Otherwise, statistics update to the managed device is disabled.
Unclassified AP Update	Enables or disables classification updates for monitored APs. If this option is enabled, there is a decrease in the delay with which the devices are classified. The default value is disabled.
Unclassified STA Update	Enables or disables classification updates for monitored clients. If this option is enabled, there is a decrease in the delay with which the devices are classified. The default value is disabled.
Unclassified Device Update Interval	The time interval, in seconds, for the AP to send the WMS a list of unclassified APs and clients. The range value is 30-36000 seconds. The default value is 60 seconds.
Wired Containment	Shows if the profile has enabled or disabled containment from the wired side.
Wired Containment of AP's Adj MACs	Shows if the profile has enabled or disabled wired containment of MACs offset by one from APs BSSID.
Wired Containment of Suspected L3 Rogue	Shows if the profile has enabled or disabled the feature to identify and contain an AP with a preset wired MAC address that is completely different from the AP's BSSID. where the MAC address that the AP provides to wireless clients as a 'gateway MAC' is offset by one character from its wired MAC address.
Wireless Containment	Shows if the profile has enabled or disabled containment from the wireless side.
Wireless Containment Deauth Reason	Specify deauth reason for containment from the wireless side. Range: 1 - 134 Default: 3

Parameter	Description
Debug Wireless Containment	Shows if the profile has enabled or disable debugging of containment from the wireless side.
Wired Containment of AP's Adj MACs	Enable or disable wired containment of MACs offset by one from APs BSSID.

Related Commands

show ids impersonation-profile

```
show ids impersonation-profile <profile-name>
```

Description

Displays an IDS Impersonation Profile. Issue this command without the <profile-name> parameter to display the IDS Impersonation Profile list. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an IDS Impersonation Profile.

Examples

The following example displays that the Mobility Conductor has five configured Impersonation Profiles:

```
(host) [mynode] (config) #show ids impersonation-profile

IDS Impersonation Profile List
-----
Name           References  Profile Status
----           -
default        4
test           0
test1          1
Wizard-test    1
Wizard-test2   1

Total: 5
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The following example displays the configuration settings for the profile **test1**:

```
(host) (config) #show ids impersonation-profile test1

IDS Impersonation Profile "test1"
-----
Parameter                               Value
-----
Detect AP Impersonation                   false
Protect from AP Impersonation             false
Beacon Diff Threshold                     50 %
Beacon Increase Wait Time                 3 sec
```

```

Detect AP Spoofing           true
Detect Beacon Wrong Channel  false
Beacon Wrong Channel Detection Quiet Time 900 sec
Detect Hotspotter Attack     true
Hotspotter Quiet Time       900 sec

```

The output of this command includes the following parameters:

Parameter	Description
Detect AP Impersonation	Shows of the profile has enabled or disabled detection of AP impersonation.
Protect from AP Impersonation	Shows if AP impersonation is enabled or disabled for the profile. When AP impersonation is detected, both the legitimate and impersonating AP are disabled using a DoS attack.
Beacon Diff Threshold	Percentage increase in beacon rates that triggers an AP impersonation event.
Beacon Increase Wait Time	Time, in seconds, after the beacon difference threshold is crossed before an AP impersonation event is generated.
Detect AP Spoofing	AP Spoofing detection is enabled
Detect Beacon Wrong Channel	Disable detection of beacons advertising the incorrect channel
Beacon Wrong Channel Detection Quiet Time	Wait 90 seconds after detecting a beacon with the wrong channel after which the check can be resumed.
Detect Hotspotter Attack	Enable detection of the Hotspotter attack to lure away valid clients.
Hotspotter Quiet Time	Wait 90 seconds after detecting an attempt to Use the Hotspotter tool against clients.

show ids management-profile

Description

Displays the management event correlation for IDS event traps and sylogs (logs).

Example

The following example displays the current management status:

```
(host) [mynode] (config) #show ids management-profile

IDS Management Profile
-----
Parameter          Value
-----          -
IDS Event Correlation    logs-and-traps
Event Correlation Quiet Time 900 sec
```

The display output of the above command includes:

Parameter	Description
IDS Event Correlation	Management profile is set for logs-and-traps.
Event Correlation Quiet Time	The time to wait, 900 seconds, before the event can be raised again.

Related Commands

show ids profile

```
show ids profile <profile-name>
```

Description

Displays all ids profiles or displays a specific profile name. Issue this command without the <profile-name> parameter to display the list of IDS Profiles. Include a profile name to display detailed information for that profile.

Parameter	Description
<profile-name>	Name of an IDS Profile.

Examples

The following example shows that the controller has seven configured IDS Profiles:

```
(host) [mynode] (config) #show ids profile

IDS Profile List
-----
Name           References  Profile Status
-----
default        5
test           0
test-tarpit    1
test-wired-lb  0
test1          0
Wizard-test    0
Wizard-test2  0

Total: 7
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The following example displays the configuration settings for the profile **test1**:

```
(host) [mynode] (config) #show ids profile test1

IDS Profile "test1"
-----
Parameter                               Value
-----
IDS General profile                       test1
IDS Signature Matching profile            test1
IDS DOS profile                           test1
```

```
IDS Impersonation profile      test1
IDS Unauthorized Device profile test1
```

The output of this command includes the following parameters:

Parameter	Description
IDS General profile	Name of a IDS General profile to be applied to an AP or AP group.
IDS Signature Matching profile	Name of a IDS Signature Matching profile to be applied to an AP or AP group.
IDS DOS profile	Name of a IDS DoS profile to be applied to an AP or AP group.
IDS Impersonation profile	Name of a IDS Impersonation profile to be applied to an AP or AP group.
IDS Unauthorized Device profile	Name of a IDS Unauthorized Device profile to be applied to an AP or AP group.

show ids rate-thresholds-profile

```
show ids rate-thresholds-profile <profile-name>
```

Description

Shows an IDS Rate Thresholds Profile. Issue this command without the <profile-name> parameter to display the IDS Rate Threshold Profile list. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an IDS Rate Threshold Profile.

Examples

The following example shows that the controller has three configured IDS Rate Threshold profiles:

```
(host) [mynode] (config) #show ids rate-thresholds-profile

IDS Rate Thresholds Profile List
-----
Name                               References  Profile Status
----                               -
default                             20
probe-request-response-thresholds  10          Predefined
test                                 0

Total: 3
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The following example displays the configuration settings for the profile **test**:

```
(host) [mynode] (config) #show ids rate-thresholds-profile test

IDS Rate Thresholds Profile "test"
-----
Parameter                          Value
-----
Channel Increase Time               15 sec
Channel Quiet Time                  900 sec
Channel Threshold                    300
Node Time Interval                   15 sec
Node Quiet Time                      900 sec
Node Threshold                       200
```

The output of this command includes the following parameters:

Parameter	Description
Channel Increase Time	Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm.
Channel Quiet Time	The time that must elapse after a channel rate alarm before another identical alarm may be triggered. This option prevents excessive messages in the log file.
Channel Threshold	Number of a specific type of frames that must be exceeded within a specific interval in an entire channel to trigger an alarm.
Node Time Interval	Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm.
Node Quiet Time	The time that must elapse after a node rate alarm before another identical alarm may be triggered. This option prevents excessive messages in the log file.
Node Threshold	Number of a specific type of frames that must be exceeded within a specific interval for a particular client MAC address to trigger an alarm.

show ids signature-matching-profile

```
show ids signature-matching-profile <profile-name>
```

Description

Shows an IDS Signature Matching Profile. Issue this command without the <profile-name> parameter to display the entire IDS Signature Matching Profile list. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an IDS Signature Matching Profile.

Examples

The following example shows that the Mobility Conductor has four configured Signature Matching Profiles:

```
(host) [mynode] (config) #show ids signature-matching-profile

IDS Signature Matching Profile List
-----
Name           References  Profile Status
-----
default        4
test1          1
Wizard-test    1
Wizard-test2   1

Total: 4
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The following example displays the configuration settings for the profile **test1**:

```
(host) [mynode] (config) #show ids signature-matching-profile test1

IDS Signature Matching Profile "test1"
-----
Parameter      Value
-----
IDS Signature   Deauth-Broadcast
IDS Signature   Disassoc-Broadcast
```

The output of this command includes the following parameters:

Parameter	Value
IDS Signature	Broadcast is not authorized.
IDS Signature	Disassociate broadcast.

Related Commands

show ids signature-profile

```
show ids signature-profile <profile-name>
```

Description

Shows an IDS Signature Profile. Issue this command without the <profile> parameter to display the entire IDS Signature Profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an IDS Signature Profile.

Examples

The following example shows that the controller has eight configured Signature Profiles:

```
(host) [mynode] (config) #show ids signature-profile

IDS Signature Profile List
-----
Name                References  Profile Status
----                -
AirJack             1          Predefined
ASLEAP              1          Predefined
Deauth-Broadcast   1          Predefined
default             1
Netstumbler Generic 1          Predefined
Netstumbler Version 3.3.0x 1          Predefined
Null-Probe-Response 1          Predefined
sample              0

Total: 8
```

The following example displays the configuration settings for the profile **AirJack**:

```
(host) [mynode] (config) # show ids signature-profile
IDS Signature Profile "AirJack" (predefined)
-----
Parameter  Value
-----
Frame Type  beacon SSID = AirJack
```

The output of this command includes the following parameters:

Parameter	Description
Frame Type	Type of 802.11 frame. For each type of frame, further parameters may be included to filter and detect only the required frames. <ul style="list-style-type: none"> ▪ assoc: Association frame type. ▪ auth: Authentication frame type. ▪ beacon: Beacon frame type. ▪ control: All control frames. ▪ data: All data frames. ▪ deauth: Deauthentication frame type. ▪ disassoc: Disassociation frame type. ▪ mgmt: Management frame type. ▪ probe-request: Probe request frame type. ▪ probe-response: Probe response frame type. ▪ ssid: For beacon, probe-request, and probe-response frame types, the SSID as either a string or hex pattern. ▪ ssid-length: For beacon, probe-request, and probe-response frame types, the length, in bytes, of the SSID.
payload	Pattern at a fixed offset in the payload of an 802.11 frame.
sequence number	Sequence number of the frame.
src- mac	Source MAC address in the 802.11 frame header.
dst- mac	Source MAC address in the 802.11 frame header.
bssid	BSSID field in the 802.11 frame header.

Description

Show an IDS Unauthorized Device Profile. Issue this command without the <profile-name> parameter to display the IDS Unauthorized Device Profile list. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an IDS Unauthorized Device Profile.

Examples

The following example shows that the Mobility Conductor has five configured Unauthorized Device Profiles:

```
(host) [mynode] (config) #show ids unauthorized-device-profile

IDS Unauthorized Device Profile List
-----
Name           References  Profile Status
-----
default        4
test           0
test1          1
Wizard-test    1
Wizard-test2   1

Total: 5
```

In the example above, the **Reference** column indicates the number of references to the profile named in the **Name** column. The **Profile Status** column is blank unless the rule is predefined.

The following example displays the configuration settings for the profile **test1**:

```
(host) [mynode] (config) #show ids unauthorized-device-profile test1

IDS Unauthorized Device Profile "test1"
IDS Unauthorized Device Profile "default"
-----

```

The output of this command includes the following parameters:

Parameter	Description
Protect 802.11n High Throughput Devices	Shows if the profile enables or disables protection of HT (802.11n) devices.

Parameter	Description
Protect 40MHz 802.11n High Throughput Devices	Shows if the profile enables or disables protection of HT (802.11n) devices operating in 40 MHz mode.
Detect Active 802.11n Greenfield Mode	Shows if the profile enables or disables detection of HT devices advertising greenfield preamble capability.
Detect AdHoc Networks	Shows if the profile has enabled or disabled detection of ad hoc networks.
Protect from Adhoc Networks	Shows if the profile has enabled or disabled protection from WPA or WPA2 ad hoc networks.
Protect from Adhoc Networks-Enhanced	Shows if the profile has enabled or disabled protection from WEP or Open ad hoc networks.
Detect Valid SSID Misuse	Shows if the detect valid SSID misuse is enabled (true) or disabled (false).
Adhoc Network Using Valid SSID Quiet Time	Shows time to wait, in seconds, after detecting an ad hoc network using a valid SSID, after which the check can be resumed.
Allow Well Known MAC	Shows if the profile allows devices with known MAC addresses to classify rogue APs.
Detect Devices with an Invalid MAC OUI	Shows if the profile has enabled or disabled checking of the first three bytes of a MAC address, known as the OUI, assigned by the IEEE to known manufacturers.
MAC OUI detection Quiet Time	Time, in seconds, that must elapse after an invalid MAC OUI alarm has been triggered before another identical alarm may be triggered.

Parameter	Description
Detect Misconfigured AP	Shows if the profile has enabled or disabled detection of misconfigured APs.
Protect Misconfigured AP	Shows if the profile has enabled or disabled protection of misconfigured APs.
Detect Bad WEP	Shows if the profile has enabled or disabled detection of WEP initialization vectors that are known to be weak or repeating.
Privacy	Shows if the profile has enabled or disabled encryption as a valid AP configuration.
Require WPA	Shows if the Mobility Conductor will flag any valid AP not using WPA as a misconfigured AP.
Valid 802.11g channel for policy enforcement	A list of valid 802.1b or 802.1g channels that third-party APs are allowed to use.
Valid 802.11a channel for policy enforcement	A list of valid 802.11a channels that third-party APs are allowed to use.
Valid and Protected SSIDs	A list of valid and protected SSIDs.
Valid MAC OUIs	A list of valid MAC OUIs.
Rogue AP Classification	Shows if the profile has enabled or disabled rogue AP classification.
Overlay Rogue AP Classification	Shows if the Mobility Conductor allows APs that are plugged into the wired side of the network to be classified as "suspected rogue" instead of "rogue".

Parameter	Description
OUI-based Rogue AP Classification	Shows if OUI-based rogue AP classification is enabled or disabled.
Propagated Wired MAC based Rogue AP Classification	Shows if rogue AP classification through propagated wired MACs is enabled or disabled.
Rogue Containment	Shows if the Mobility Conductor will automatically shut down rogue APs.
Suspected Rogue Containment	Shows if the Mobility Conductor will automatically treat suspected rogue APs as interfering APs.
Suspected Rogue Containment Confidence Level	Confidence level of suspected Rogue AP to trigger containment, expressed as a percentage.
Detect Station Association To Rogue AP	Shows if the profile has been configured to detect station association to a rogue AP.
Detect Unencrypted Valid Clients	Shows if the profile has enabled or disabled detection of unencrypted valid clients.
Unencrypted Valid Client Detection Quiet Time	Shows the time to wait, in seconds, after detecting an unencrypted valid client after which the check can be resumed.
Detect Valid Client Misassociation	Shows if the profile has enabled or disabled detection of a misassociation between a valid client and an unsafe AP.
Detect Valid SSID Misuse	Shows if the profile has enabled or disabled detection of Interfering or Neighbor APs using valid or protected SSIDs.
Protect SSID	Shows if the profile has enabled or disabled use of SSID by valid APs only.

Parameter	Description
Protect Valid Stations	Shows if the Mobility Conductor will allow valid stations to connect to a non-valid AP.
Valid Wired MACs	List of valid and protected SSIDs.
Vendor Specific OUI/OUI-Type for containment exclusion	Shows the details of vendor specific IE information for containment exclusion.
Detect Windows Bridge	Shows if the profile has enabled or disabled detection of Windows station bridging.
Protect Windows Bridge	Shows if the profile has enabled or disabled protection of Windows station bridging.
Detect Wireless Bridge	Shows if the profile has enabled or disabled detection of wireless bridging.
Wireless Bridge detection Quiet Time	Time, in seconds, that must elapse after a wireless bridge alarm has been triggered before another identical alarm may be triggered.
Protect From Wireless Hosted Networks	Shows if the profile has enabled or disabled detection of a wireless hosted network.
Wireless Hosted Network Quiet Time	The wireless hosted network detection feature sends a log message and trap when a wireless hosted network is detected. The quiet time displayed in this field displays the amount of time, in seconds, that must elapse after a wireless hosted network log message or trap has been triggered before an identical log message or trap can be sent again.

Parameter	Description
Protect From Wireless Hosted Networks	Shows if the profile has enabled or disabled containment on a wireless hosted network by launching a DoS attack to disrupt associations between a Windows 7 software-enabled Access Point (softAP) and a client, and disrupt associations between the client that is hosting the softAP and any access point to which the host connects.

show ids wms-general-profile

```
show ids wms-general-profile
```

Description

Displays general statistics for the wms configuration.

Example

The following example shows per-channel statistics for all monitored APs:

```
(host) [mynode] (config) #show ids wms-general-profile

IDS WMS General Profile
-----
Parameter                               Value
-----
AP poll interval                         60000 msec
AP poll retries                           3
AP ageout interval                       0 minutes
Adhoc AP ageout interval                 31 minutes
Station ageout interval                 100 minutes
Statistics update                         true
Persistent Neighbor APs                  true
Persistent Valid STAs                    false
AP learning                              false
Propagate Wired Macs                     true
Collect Stats for Monitored APs and Clients false
Learn System Wired Macs                   false
```

The output of this command includes the following information:

Column	Description
AP poll interval	Interval, in milliseconds, for communication between the controller and AMs. The controller contacts the AM at this interval to download AP to station associations, update policy configuration changes, and download AP and station statistics.
AP poll retries	Maximum number of failed polling attempts before the polled AM is considered to be down.
AP ageout interval	Time, in minutes, that an AP must remain unseen by any probes before it is deleted from the database.

Column	Description
Adhoc AP ageout interval	Time, in minutes, that an ad hoc (IBSS) AP remains unseen before it is deleted (ageout) from the database.
Station ageout interval	Time, in minutes, that a client must remain unseen by any probes before it is deleted from the database.
Statistics update	Shows the status of the statistics updates in the database.
Persistent Neighbor APs	Shows the status of known AP neighbors.
Persistent Valid STAs	Shows the status of known AP neighbors.
AP learning	Shows the status of "learning" of non-Aruba APs.
Propagate Wired Macs	Shows if the controller has enabled or disabled the propagation of the gateway wired MACs.
Collect Stats for Monitored APs and Clients	Shows if the master/ conductor controller will collect up to 25,000 statistic entries for monitored APs and clients.
Learn System Wired Macs	Shows the status of "learning" of wired MACs at the controller.

Related Commands

All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ids wms-local-system-profile

```
ids wms-local-system-profile
max-ap-threshold <max-ap-threshold>
```

Description

Displays statistics for the WMS Local System Profile settings. The configuration parameters in IDS WMS Local System Profile enables local termination of the WMS service, sets maximum thresholds for the maximum number of managed APs and stations, and defines the intervals at which valid AP, rogue AP, and station data is sent to the managed device. Issue this command to view the local WMS service profile settings .

Example

The following commands first set the interval time for repopulating the MAC table to 10 minutes and then sets the maximum number of APs to 100:

```
(host)[mynode] (config) #show ids wms-local-system-profile
IDS WMS Local System Profile
-----
Parameter                               Value      Set
-----
Max AP Threshold                         100
Max STA Threshold                        0
Max RBTtree Entries                      3
Max System Wired MACs                    1000
Override Service Termination            false
Periodic AP Snapshot Interval           180 minutes
Periodic Rogue AP Snapshot Interval     30 minutes
Periodic STA Snapshot Interval          180 minutes
System Wired MAC Update Interval         8
```

The output of this command includes the following information:

Table 12: *IDS WMS Local System Profile Settings*

Parameter	Description
Max AP Threshold	The max threshold for the total number of APs.
Max STA Threshold	The max threshold for the total number of stations.
Max RBTtree Entries	The max threshold for the total number of AP and station RBTtree entries.
Max System Wired MACs	The max number of system wired MAC table entries learned by the managed device.

Parameter	Description
Override Service Termination	If enabled, this feature overrides the system-determined termination mode, and terminates WMS service at the managed device to which the AP is associated.
Periodic AP Snapshot Interval	The interval in minutes at which to generate a periodic snapshot of monitored APs. The (AMON) messages comprising the snapshot will be spread over this interval.
Periodic Rogue AP Snapshot Interval	The interval in minutes at which to generate a periodic snapshot of monitored Rogue APs. The (AMON) messages comprising the snapshot will be spread over this interval.
Periodic STA Snapshot Interval	The interval in minutes at which to generate a periodic snapshot of monitored clients. The (AMON) messages comprising the snapshot will be spread over this interval.
System Wired MAC Update Interval	The interval, in minutes, for repopulating the system wired MAC table at the managed device.

Related Commands

show ifmap

Syntax

```
show ifmap
  cppm
  state cppm
  statistics cppm
```

Descriptions

Issue this command to show the ClearPass Policy Manager IF-MAP configuration profile and the IP-MAP connection state.

Parameter	Description
cppm	Shows the ClearPass Policy Manager IF-MAP profile parameters and their values.
state cppm	Shows the ClearPass Policy Manager IF-MAP connection state including if it is enabled, and the servers and their state.
statistics cppm	Shows the statistics data.

Example

To configure this feature using the CLI:

```
(host) [mynode] (config) #ifmap
(host) [mynode] (config) #ifmap cppm
(host) [mynode] (CPPM IF-MAP Profile) #server host <host>
(host) [mynode] (CPPM IF-MAP Profile) #port <port>
(host) [mynode] (CPPM IF-MAP Profile) #passwd <psswd>
(host) [mynode] (CPPM IF-MAP Profile) #enable
```

This show command show if the CCPM interface is enable and the ClearPass Policy Manager server IP address, username and password.

```
(host)[mynode] (CPPM IF-MAP Profile) #show ifmap cppm
CPPM IF-MAP Profile
-----
Parameter                Value
-----
CPPM IF-MAP Interface    Enabled
CPPM IF-MAP Server       10.10.10.10:443 admin/*****
```

This show command shows if state of all enabled ClearPass Policy Manager servers.

```
(host)[mynode] (CPPM IF-MAP Profile) #show ifmap state cppm
CPPM IF-MAP Connection State [Interface: Enabled]
-----
Server                State
-----

```

Related Commands

Command	Description
ifmap	This command is used in conjunction with ClearPass Policy Manager. It sends HTTP User Agent Strings and mDNS broadcast information to ClearPass so that it can make more accurate decisions about what types of devices are connecting to the network

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode

show image version

Syntax

```
show image version  
type
```

Description

Display the current system image version on both partition 0 and 1.

Parameter	Description
type	Displays the System image type.

Example

The following example shows that the managed device is running ArubaOS 8.0 and booting off partition 0:1.

```
(host)[mynode] #show image version  
-----  
Partition           : 0:0 (/mnt/disk1)  
Software Version    : ArubaOS 8.0.0.0-svcs-ctrl (Digitally Signed -  
Developer/Internal Build)  
Build number        : 0000  
Label               : ssetty@ss_sc_new-ENG.0000  
Built on            : Wed Jun 8 14:46:22 IST 2016  
-----  
Partition           : 0:1 (/mnt/disk2) **Default boot**  
Software Version    : ArubaOS 8.0.0.0-svcs-ctrl (Digitally Signed -  
Developer/Internal Build)  
Build number        : 0000  
Label               : ssetty@ss_sc_new-ENG.0000  
Built on            : Thu Jun 16 12:53:57 IST 2016
```

The output of this command includes the following parameters:

Parameter	Description
Partition	Partition number and name. The default boot partition will display a **Default boot** notice by the partition name.
Software Version	Version of ArubaOS software running on the partition.

Parameter	Description
Build number	Build number for the software version.
Label	The label parameter can display additional information for the build. By default, this value is the software build number.
Built on	Date the software build was created.

Following is an example of `show image version type` command:

```
(host) [mynode] #show image version type
This image is development build
```

Related Commands

Command	Description
show ap image-preload status	This command displays the list of APs that will preload a new version of software from a controller with the AP preload feature activated.

show interface

```
show interface
  cellular
  counters
  gigabitethernet
  list
  loopback
  mgmt
  port-channel
  tunnel
  vlan
```

Description

This command displays the list of all interfaces. Click the parameter links below to view the corresponding show commands.

Parameter	Description
cellular	Displays the access groups configured on the cellular interface.
counters	Displays a table of L2 interfaces counters.
gigabitethernet	Displays information about a specified Gigabit Ethernet port.
list	Displays interfaces for all platforms supported by current SC version.
loopback	Displays information about the Loopback IP interface.
mgmt	Displays information about management Ethernet IP interfaces.
port-channel	Displays information about a specified port-channel interface.
tunnel	Displays information about tunnel interfaces.
vlan	Displays information about a specified VLAN interface.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show interface cellular access-group

show interface cellular access-group

Description

Lists the access groups configured on the cellular interface.

Example

```
(host) [mynode] #show interface cellular access-group
Cell Interface:
session access list 3 is configured
```

Related Commands

Command	Description
interface cellular	This command allows you to specify an ingress or egress ACL to the cellular interface of an EVDO modem.

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show interface counters

show interface counters

Description

Displays a table of L2 interfaces counters.

Example

The example below shows the output of the `show interface counters` command:

```
(host) [mynode] #show interface counters
Port          InOctets      InUcastPkts   InMcastPkts
InBcastPkts
GE0/0/0       87071474     45349         590754       112566
Port          OutOctets     OutUcastPkts  OutMcastPkts
OutBcastPkts
GE0/0/0       10646801    18727         581          2
```

The output of this command includes the following parameters:

Parameter	Description
Port	Port number.
InOctets	Number of octets received through the port.
InUcastPkts	Number of unicast packets received through the port.
InMcastPkts	Number of multicast packets received through the port.
InBcastPkts	Number of broadcast packets received through the port.
OutOctets	Number of octets sent through the port.
OutUcastPkts	Number of unicast packets sent through the port.
OutMcastPkts	Number of multicast packets sent through the port.
OutBcastPkts	Number of broadcast packets sent through the port.

Related Commands

Command	Description
interface range	This command configures a range of GigabitEthernet interfaces on the managed device.
interface tunnel	This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device.
interface vlan	This command configures a VLAN interface.
interface vlan ip igmp	This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show interface gigabitethernet

show interface gigabitethernet <slot/module/port>

Description

Displays information about a specified Gigabit Ethernet port.

Parameter	Description
access-group	Displays the Access Groups configured on this interface.
counters	Displays L2 interface counters for the specified interface.
switchport	Displays L2 interface information.
transceiver	Displays the transceiver serial ID information.
trusted-vlan	Displays port member vlan trusted status.
untrusted-vlan	Displays port member vlan untrusted status.
xsec	Displays xsec configuration.

Examples

The example below shows the output of `show interface gigabitethernet 0/0/0`:

```
(host)[mynode] (config) #show interface gigabitethernet 0/0/0
GE 0/0/0 is up, line protocol is up
Hardware is 10 Gigabit Ethernet, address is 00:0C:29:37:AB:82 (bia
00:0C:29:37:AB:82)
Description: GE0/0/0
Encapsulation ARPA, loopback not set
speed (10 Gbps)
MTU 1500 bytes, BW is 10000 Mbit
Last clearing of "show interface" counters 5 day 4 hr 57 min 41 sec
link status last changed 5 day 4 hr 55 min 22 sec
1560452 packets input, 498781462 bytes
Received 240098 broadcasts, 0 runts, 0 giants, 0 throttles
0 input error bytes, 0 CRC, 0 frame
240098 multicast, 1320354 unicast
1149614 packets output, 158075706 bytes
0 output errors bytes, 0 deferred
0 collisions, 0 late collisions, 0 throttles
This port is TRUSTED
```

The output of this command includes the following parameters:

Parameter	Description
GE 0/0/0 is...	Displays the status of the specified port.
line protocol is...	Displays the status of the line protocol on the specified port.
Hardware is...	Describes the hardware interface type.
address is...	Displays the MAC address of the hardware interface.
Description	The port type, name, and connector type.
Encapsulation	Encapsulation method assigned to this port.
loopback...	Displays whether or not loopback is set.
Configured	Configured transfer operation and speed.
Jumbo support...	Jumbo frame support is enabled.
Negotiated	Negotiated transfer operation and speed.
MTU bytes	MTU size of the specified port in bytes.
BW is...	Bandwidth of the link.
Last clearing of "show interface counters"	Time since "show interface counters" was cleared.
link status last changed...	Time since "show interface counters" was cleared. Below the time, all current counters related to the specified port are listed.
This port is...	Whether or not this port is trusted.
POE status of the port is...	The POE status of the specified port.
BW-Contract List/ Application Exception List/ Application BW-Contract list	Information about the bandwidth contract applied to the interface. For details, see interface gigabitethernet .

The example below shows the output of `show interface gigabitethernet 0/0/0 counters`:

```
(host)[mynode] (config) #show interface gigabitethernet 0/0/0 counters
Port          InOctets      InUcastPkts   InMcastPkts
InBcastPkts
GE0/0/0      498972448     1321416       240316        0
```

Port	OutOctets	OutUcastPkts	OutMcastPkts
OutBcastPkts GE0/0/0	158234051	1150823	0

The output of this command includes the following parameters:

Parameter	Description
Port	Port number.
InOctets	Number of octets received through the port.
InUcastPkts	Number of unicast packets received through the port.
InMcastPkts	Number of multicast packets received through the port.
InBcastPkts	Number of broadcast packets received through the port.
OutOctets	Number of octets sent through the port.
OutUcastPkts	Number of unicast packets sent through the port.
OutMcastPkts	Number of multicast packets sent through the port.
OutBcastPkts	Number of broadcast packets sent through the port.

The example below shows the output of `show interface gigabitethernet 0/0/0 switchport`:

```
(host)[mynode] (config)#show interface gigabitethernet 0/0/0 switchport

Name: GE0/0/0
Switchport: Enabled
Administrative mode: static access
Operational mode: static access
Administrative Trunking Encapsulation: dot1q
Operational Trunking Encapsulation: dot1q
Access Mode VLAN: 1 (Default)
Trunking Native Mode VLAN: 1 (Default)
Trunking Vlans Enabled: NONE
Trunking Vlans Active: NONE
```

The output of this command includes the following parameters:

Parameter	Description
Name	Port name.
Switchport	Whether or not switchport is enabled.

Parameter	Description
Administrative mode	Administrative mode .
Operational mode	Operational mode.
Administrative Trunking Encapsulation	Encapsulation method used for administrative trunking.
Operational Trunking Encapsulation	Encapsulation method used for operational trunking.
Access Mode VLAN	The access mode VLAN for the specified port.
Trunking Native Mode VLAN	The trunking native mode VLAN for the specified port.
Trunking Vlans Enabled	Number of trunking VLANs currently enabled.
Trunking Vlans Active	Number of trunking VLANs currently active.

The example below shows the output of `show interface gigabitethernet 0/0/2 transceiver`:

```
(host)[mynode] (config)#show interface gigabitethernet 0/0/2 transceiver

Module is SFP+
Product Number      : J9151E  HPE
Part Number         : 1990-4727, rev: 10
S/N                 : CN01KBW0FL
Date Code           : 200107 Lot:
Supported Modes     : 10GBASE-LR, LC Connector
Wavelength          : 1310 nm
Aruba Certified     : YES
```

The output of this command includes the following parameters:

Parameter	Description
Module	Indicates the SFP transceiver module.
Product Number	Denotes the product number.
Part Number	Part number provided by the SFP vendor.
S/N	Serial number provided by the SFP vendor.
Date Code	Denotes the vendor's manufacturing date code. It consists of 6 numbers each, two of them represent year, month and day of month respectfully. It also includes a vendor specific lot code which may be blank.

Parameter	Description
Supported Modes	Denotes the transceiver type and the description value.
Wavelength	Displays the wavelength in nm.
Aruba Certified	Displays if the SFP transceiver is certified by Aruba.

The example below shows the output of `show interface gigabitethernet 0/0/0 untrusted-vlan`:

```
(host) [mynode] (config)#show interface gigabitethernet 0/0/0 untrusted-vlan
Name: GE1/0
Untrusted Vlan(s)
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the specified port.
Untrusted Vlan(s)	List of untrusted VLANs.

The example below shows the output of `show interface gigabitethernet 0/0/1 xsec`:

```
(host) [mynode] (config)# show interface gigabitethernet 0/0/1 xsec
xsec vlan 7 is ACTIVE
```

The output of this command includes the following parameters:

Parameter	Description
xsec vlan 7 is ACTIVE	This states that xsec is active on the specified port as well as the associated VLAN.

Related Commands

Command	Description
interface range	This command configures a range of GigabitEthernet interfaces on the managed device.

Command	Description
interface tunnel	This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device.
interface vlan	This command configures a VLAN interface.
interface vlan ip igmp	This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Command History

Release	Modification
ArubaOS 8.10.0.0	The <code>Aruba Certified</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show interface list

```
show interface list
```

Description

Lists the interfaces for all platforms supported by current SC version.

Example

```
(host) [mynode] #show interface list

Platforms: A7210, A7220, A7240

interface gigabitethernet 0/0/0
```

```
interface gigabitethernet 0/0/1
interface gigabitethernet 0/0/2
interface gigabitethernet 0/0/3
interface gigabitethernet 0/0/4
interface gigabitethernet 0/0/5
```

Platforms: A9240, A9240_silver

```
interface gigabitethernet 0/0/0
interface gigabitethernet 0/0/1
interface gigabitethernet 0/0/2
interface gigabitethernet 0/0/3
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show interface loopback

show interface loopback

Description

Displays information about the loopback IP interface.

Example

The example below shows the output of the `show interface loopback` command:

```
(host) [mynode] #show interface loopback

loopback interface is up line protocol is up
Hardware is Ethernet, address is 00:0C:29:37:AB:81
IPv6 link-local address is fe80::c:290f:ff37:ab81/64
```

The output of this command includes the following parameters:

Parameter	Description
loopback interface is...	Status of the loopback interface.
line protocol is...	Status of the line protocol on the specified port.
Hardware is...	Hardware interface type.
address is...	MAC address of the loopback interface.
IPv6 link-local address	IP address and subnet mask of the loopback interface.

Related Commands

Command	Description
interface range	This command configures a range of GigabitEthernet interfaces on the managed device.
interface tunnel	This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device.
interface vlan	This command configures a VLAN interface.

Command	Description
interface vlan ip igmp	This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable or config mode on Mobility Conductor.

show interface mgmt

show interface mgmt

Description

Displays information about management Ethernet IP interfaces.

Example

The example below shows the output of `show interface mgmt`:

```
(host) [mynode] (config)# show interface mgmt

mgmt is up line protocol is up
Hardware is Ethernet, address is 00:0C:29:37:AB:77
```

The output of this command includes the following parameters:

Parameter	Description
mgmt is...	Status of the mgmt interface.
line protocol is...	Status of the line protocol on the specified port.
Hardware is...	Describes the hardware interface type.
address is...	Interface's MAC address.

Related Commands

Command	Description
interface mgmt	This command configures the out-of-band Ethernet management port on controller.
interface range	This command configures a range of GigabitEthernet interfaces on the managed device.
interface tunnel	This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device.
interface vlan	This command configures a VLAN interface.

Command	Description
interface vlan ip igmp	This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command Introduced.

Command Information

show interface port-channel

```
show interface port-channel <id>
  access-group
  counters
  switchport
  trusted-vlan
  untrusted-vlan
  xsec
    xsec point-to-point
```

Description

Displays information about a specified port-channel interface.

Parameter	Description
access-group	Displays access groups configured on this interface.
counters	Displays L2 interface counters for the specified interface.
switchport	Displays L2 interface information for the specified interface.
trusted-vlan	Displays port member vlan trusted status.
untrusted-vlan	Displays port member vlan untrusted status.
xsec	Displays xsec configuration.
xsec point-to-point	Displays the point-to-point xsec tunnels for the specified interface.

Examples

The examples below show the output of `show interface port-channel 7` on a managed device.

```
(host) [mynode] (config) #show interface port-channel 7
Port-Channel 7 is administratively up, Link is up, Line protocol is down
Hardware is Port-Channel, address is 00:0C:29:37:AB:81 (bia
00:0C:29:37:AB:81)
Description: Link Aggregate
Spanning Tree is Discarding
Switchport priority: 0
Member port(s):
Speed :0 Mbps
Interface index: 8200
MTU: 1500 bytes
Last clearing of "show interface" counters 0 day 8 hr 48 min 3 sec
link status last changed 0 day 8 hr 48 min 3 sec
```

```

0 packets input, 0 bytes
Received 0 broadcasts, 0 runts, 0 giants, 0 throttles
0 input error bytes, 0 CRC, 0 frame
0 multicast, 0 unicast
0 packets output, 0 bytes
0 output errors bytes, 0 deferred
0 collisions, 0 late collisions, 0 throttles
Port-Channel 7 is NOT TRUSTED

```

The output of this command includes the following parameters:

Parameter	Description
Port-Channel 7 is...	Status of the specified port.
line protocol is...	Status of the line protocol on the specified port.
Hardware is....	Hardware interface type.
address is...	MAC address of the hardware interface.
Description	The port type, name, and connector type. If the LAG is created by LACP, it is indicated as shown in the display output above. If the LAG is created by LACP, you can not statically add or delete any ports under that port channel. All other commands are allowed. If LACP is not shown, then the LAG is created by static configuration.
Spanning Tree is...	Spanning tree status on the specified port-channel.
VLAN membership	Number of VLANs the specified port-channel is associated with.
Switchport priority	Switchport priority of the specified port-channel.
Jumbo Support is...	Displays the status of jumbo frame on a port channel.
Last clearing of "show interface counters"	Time since "show interface counters" was cleared. Below the time, all current counters related to the specified port are listed.
Port-channel 7 is...	Whether or not this port-channel is trusted.

```

Port-Channel 7:

Port-Vlan Session ACL
-----
SessionACL          Vlan      Status
-----          -----

```

The output of this command includes the following parameters:

Parameter	Description
SessionACL	Session ACL name.
Vlan	VLAN number.
Status	ACL status.

```

#show interface port-channel 7 counters
Port          InOctets      InUcastPkts    InMcastPkts    InBcastPkts
PC 0:         0              0              0              0
Port          OutOctets      OutUcastPkts   OutMcastPkts   OutBcastPkts
PC 0:         0              0              0              0

```

The output of this command includes the following parameters:

Parameter	Description
PC	Port number.
InOctets	Number of octets received through the port.
InUcastPkts	Number of unicast packets received through the port.
InMcastPkts	Number of multicast packets received through the port.
InBcastPkts	Number of broadcast packets received through the port.
OutOctets	Number of octets sent through the port.
OutUcastPkts	Number of unicast packets sent through the port.
OutMcastPkts	Number of multicast packets sent through the port.
OutBcastPkts	Number of broadcast packets sent through the port.

```

#show interface port-channel 7 trusted-vlan

```

```
Name: Port-channel 7
Switchport: Enabled
Administrative mode: static access
Operational mode: static access
Administrative Trunking Encapsulation: dot1q
Operational Trunking Encapsulation: dot1q
Access Mode VLAN: 1 (Default)
Trunking Native Mode VLAN: 1 (Default)
Trunking Vlans Enabled: NONE
Trunking Vlans Active: NONE
```

The output of this command includes the following parameters:

Parameter	Description
Name	Port name.
Switchport	Whether or not switchport is enabled.
Administrative mode	Administrative mode .
Operational mode	Operational mode.
Administrative Trunking Encapsulation	Encapsulation method used for administrative trunking.
Operational Trunking Encapsulation	Encapsulation method used for operational trunking.
Access Mode VLAN	The access mode VLAN for the specified port.
Trunking Native Mode VLAN	The trunking native mode VLAN for the specified port.
Trunking Vlans Enabled	Number of trunking VLANs currently enabled.
Trunking Vlans Active	Number of trunking VLANs currently active.

```
#show interface port-channel 7 trusted-vlan

Name: Port-Channel7
Trusted Vlan(s)
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the specified port.
trusted Vlan(s)	List of trusted VLANs.

```
#show interface port-channel 7 untrusted-vlan

Name: FE1/0
Untrusted Vlan(s)
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the specified port.
Untrusted Vlan(s)	List of untrusted VLANs.

```
#show interface port-channel 7 xsec

xsec vlan 7 is ACTIVE
```

The output of this command includes the following parameters:

Parameter	Description
xsec vlan 7 is ACTIVE	This states that xsec is active on the specified port as well as the associated VLAN.

Related Commands

Command	Description
interface mgmt	This command configures the out-of-band Ethernet management port on controller.
interface port-channel	This command configures an Ethernet port channel.
interface range	This command configures a range of GigabitEthernet interfaces on the managed device.
interface tunnel	This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device.
interface vlan	This command configures a VLAN interface.

Command	Description
interface vlan ip igmp	This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or config mode on Mobility Conductor.

show interface tunnel

```
show interface tunnel <id> {trusted-vlan | untrusted-vlan}
```

Description

Displays information about tunnel interfaces.

Parameter	Description
id	Tunnel interface number.
trusted-vlan	Displays trusted VLAN list.
untrusted-vlan	Displays untrusted VLAN list.

Examples

The example below shows the output of `show interface tunnel` for IPv4:

```
(host) [mynode] #show interface tunnel 2000

Tunnel stats last fetched from SOS: 8 sec ago
Tunnel 2000 is up line protocol is down
Description: Tunnel Interface
Source 10.16.33.208 (Vlan 33)
Destination 1.1.1.200
Tunnel mtu is set to 1100
Tunnel is a Layer2 GRE TUNNEL
Tunnel is Trusted
Inter Tunnel Flooding is enabled
Tunnel keepalive is enabled
Keepalive type is Default
Tunnel keepalive interval is 1 seconds, retries 1
Heartbeats sent 1992, Heartbeats lost 1991
Tunnel is down 2 times
Trusted vlans:350-850
tunnel vlan 300-900
RxBytes: 0, TxBytes: 384, Encaps: 6, Decaps: 0
```

The example below shows the output of `show interface tunnel` for IPv6:

```
(host) [mynode] #show interface tunnel 20

Tunnel stats last fetched from SOS: 8 sec ago
Tunnel 20 is up line protocol is up
Description: Tunnel Interface
Source 2001:10:16:32::54 (Vlan 32)
```

```

Destination 2001:10:16:32::53
Tunnel mtu is set to 1500
Tunnel is a Layer2 GRE TUNNEL
Tunnel is Trusted
Inter Tunnel Flooding is enabled
Tunnel keepalive is disabled
Keepalive type is Default
Tunnel keepalive interval is 0 seconds, retries 0
Trusted vlan 300-350
tunnel vlan 100,200,300-350
RxBytes: 0, TxBytes: 384, Encaps: 6, Decaps: 0

```

The example below shows the output of `show interface tunnel` for trusted vlan:

```

(host) [mynode] #show interface tunnel 30 trusted-vlan
Trusted Vlan(s):300-350

```

The example below shows the output of `show interface tunnel` for untrusted vlan:

```

(host) [mynode] #show interface tunnel 40 untrusted-vlan
Untrusted Vlan(s):1-299,351-4094

```

The output of this command includes the following parameters:

Parameter	Description
Tunnel stats last fetched from SOS: 8 sec ago	Displays when the tunnel statistics were last fetched from SOS. This parameter is printed only once.
Tunnel 2000 is up line protocol is down	Displays the status of the specified interface tunnel and its line protocol.
Description	Displays the description of the specified interface tunnel.
Source	Displays the IP address of the source of the specified interface tunnel.
Destination	Displays the IP address of the destination of the specified interface tunnel.
Tunnel mtu is set to 1100	Displays the MTU size of the specified interface tunnel.

Parameter	Description
Tunnel is a Layer2 GRE TUNNEL	Displays the layer 2 or layer 3 status of the specified interface tunnel.
Tunnel is trusted	Displays whether or not the specified interface tunnel is trusted.
Inter tunnel flooding is enabled	Displays whether or not the inter tunnel flooding of the specified interface tunnel is enabled.
Tunnel keepalive is disabled	Displays whether or not the tunnel keepalive of the specified interface tunnel is enabled.
Keepalive type is Default	Displays the type of the keepalive of the specified interface tunnel.
Tunnel keepalive interval is 1 seconds, retries 1	Displays the keepalive interval and number of retries configured on the specified interface tunnel.
Heartbeats sent 1992, Heartbeats lost 1991	Displays the number of heartbeats sent and lost on the specified interface tunnel.
Tunnel is down 2 times	Displays the number of times the tunnel was down on the specified interface tunnel.
Trusted vlans:350-850	Displays the VLAN IDs that are trusted on the specified interface tunnel.
tunnel vlan 300-900	Displays the VLAN IDs that are part of the tunnel in the specified interface tunnel.
RxBytes: 0, TxBytes: 384, Encaps: 6, Decaps: 0	Displays the number of sent, received, encapsulated, and decapsulated packets.

Related Commands

Command	Description
interface mgmt	This command configures the out-of-band Ethernet management port on controller.

Command	Description
interface range	This command configures a range of GigabitEthernet interfaces on the managed device.
interface tunnel	This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device.
interface vlan	This command configures a VLAN interface.
interface vlan ip igmp	This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

Command History

Release	Modification
ArubaOS 8.7.0.0	The <code>Tunnel stats last fetched from SOS</code> and <code>RxBytes:</code> , <code>TxBytes:</code> , <code>Encaps:</code> , <code>Decaps:</code> parameters were introduced.
ArubaOS 8.4.0.0	The <code>trusted-vlan</code> and <code>untrusted-vlan</code> sub-parameters was introduced in the following command. <ul style="list-style-type: none"> ■ <code>show interface tunnel <id></code>
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show interface vlan

```
show interface vlan <id> [access-group]
```

Description

Displays information about a specified VLAN interface.

Parameter	Description
<id>	VLAN interface number.
access-group	Session ACL configured on this interface.

Example

The following example displays information about VLAN 20:

```
(host) [mynode] #show interface vlan 20

VLAN20 is up line protocol is up
Hardware is CPU Interface, Interface address is 00:0C:29:3C:F7:D3 (bia
00:0C:29:3C:F7:D3)
Description: 802.1Q VLAN
IPv6 is enabled, link-local address is fe80::c:2900:143c:f7d3
Global unicast address(es):
2017::1, subnet is 2017::/64
IPv6 Router Advertisements are disabled
Routing interface is enable, Forwarding mode is enable
Directed broadcast is disabled, BCMC Optimization disabled ProxyARP disabled
Suppress ARP enable
Encapsulation 802, loopback not set
MTU 1500 bytes
Last clearing of "show interface" counters 1 day 2 hr 55 min 37 sec
link status last changed 1 day 0 hr 37 min 24 sec
Proxy Arp is disabled for the Interface
IPv6 Helper Addresses Configured on this Interface:
2001:200::1
DHCPv6 relay option is configured on this interface
```

The output of this command includes the following parameters:

Parameter	Description
VLAN1 is...	Status of the specified VLAN.
Line protocol is...	Displays the status of the line protocol on the specified port.

Parameter	Description
Hardware is...	Describes the hardware interface type.
Interface address is...	Displays the MAC address of the hardware interface.
Description	Description of the specified VLAN.
Internet address is...	IP address and subnet mask of the specified VLAN.
IPv6 Router Advertisements...	Status of IPv6 RA.
Routing interface is...	Status of the routing interface.
Forwarding mode is...	Status of the forwarding mode.
Directed broadcast is...	Displays whether or not directed broadcast is enabled.
BCMC Optimization...	Status of broadcast-multicast optimization.
ProxyARP...	Status of proxy ARP. Proxy ARP is a technique by which a device on a given network answers the ARP queries for a network address that is not on that network.
Supress ARP...	Status of suppressed ARP. If enabled, the managed device prevents flooding of ARP broadcasts on all the untrusted interfaces.
Encapsulation	Encapsulation type.
Loopback...	Loopback status.
MTU	MTU size of the specified port in bytes.
Last clearing of "show interface counters"	Time since show interface counters was cleared.
link status last changed	Time since link status last changed.
Proxy ARP is...	Status of proxy ARP on the specified interface.
IPv6 Helper Addresses...	Helper address configured for a vlan.

show inventory

show inventory

Description

This command displays the hardware inventory of Mobility Conductor or the managed device.

Example

Execute this command to display the hardware component inventory of Mobility Conductor.

```
(host) [mynode] #show inventory

Mgmt Port HW MAC Addr      : 00:0C:29:71:10:0B
HW MAC Addr                 : 00:0C:29:71:10:15
System Serial#             : DC0604083
Activate license            : Not applicable
Supported device type      : MM
Active device type         : MM
```

Issue this command to display the hardware component inventory of the managed device. The output of this command will vary depending on the controller platform type.

```
(host-md) #show inventory

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor and Enable mode on Managed Device.

show iot

```
show iot
  manager
  transportProfile
  radio-profile
  iostat
```

Description

This command displays the list of all interfaces. Click the parameter links below to view the corresponding show commands.

Parameter	Description
manager	Displays the status of the IoT manager.
transportProfile	Displays the list of IoT transport profiles and the context and status of the IoT transport profiles.
radio-profile	Displays the list of IoT radio profiles and the context and status of the IoT radio profiles.
iostat	Displays Input/Output statistics information. This command reports Central Processing Unit (CPU) statistics and Input/Output statistics for devices and partitions.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

Parameter	Description
swap	The number of swap pages that have been brought in and out.
intr	The number of interrupts received from the system boot.
disk_io	(x,y) is (major, minor):(xx, xx, xxxx, x, x) is (noinfo, read_io_ops, blks_read, write_io_ops, blks_written).
ctxt	The number of context switches that the system underwent.
btime	The boot time, in seconds.
processes	The number of forks since boot.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show iot radio-profile

```
show iot radio-profile [<profile-name>]
```

Description

This command displays the list of IoT radio profiles and the context and status of the IoT radio profiles.

Examples

The following example shows the list and context of IoT transport profiles:

```
(host) [mynode] #show iot radio-profile

IoT Radio Profile List
-----
Name                References  Profile Status
-----
Sample-Ble          0
Sample-Zigbee       0

Total: 2
```

The following example shows the status of an IoT radio profile:

```
(host) [mynode] #show iot transportProfile Sample-Zigbee

IoT Data Profile "Sample-Zigbee"
-----
Parameter                Value
-----
Radio Instance            internal
Radio Mode                zigbee
Radio Enable              Enabled
ZipBee Opmode             coordinator
ZipBee Channel            auto
ZipBee Permit Joining    on
ZipBee Permit Joining Duration 300
ZipBee PAN ID Type       auto
ZipBee PAN ID             0000
```

show iot-manager

```
Show iot-manager
  ble-services ibeacon-info [ap-group <ap-group>] [ble-profile <ble-profile>]
  debug db-dump-status
  debug db-optimize-status
  log level
```

Description

This command shows the status of the IoT manager.

Parameter	Description
ble-services ibeacon-info	This parameter shows the iBeacon information of devices.
ap-group <ap-group>	This parameter filters the iBeacon information of devices by the ap-group.
ble-profile <ble-profile>	This parameter filters the iBeacon information of devices by the BLE profile.
debug db-dump-status	This parameter shows the database dump status information.
debug db-optimize-status	This parameter shows the database optimization status information.
log	This parameter shows the logs from IoT manager process.

Examples

Access the CLI and use the following command to show the status of the IoT manager:

```
(host) [mynode] #show iot-manager debug db-dump-status

IM DB dump status
-----
Field          Value
-----
Status:        Success
Filename:      im_db_dump.tgz
Begin Time:    2019-04-30 06:47:48
End Time:      2019-04-30 06:47:48
```

Access the CLI and use the following command to show the status of the IoT manager:

```
(host) [mynode] #show iot-manager ble-service ibeacon-info profile default

AP's BLE radio iBeacon parameter
-----
AP Eth MAC          BLE MAC          Radio instance Major  Minor  UUID
-----
38:17:c3:c0:c8:ba  7c:01:0a:ff:22:22 internal 1000  1000  4152554E-F99B-
4A3B-86D0-947070693A78

Total AP BLE devices reported: 1
```

Related Commands

Command	Description
iot-manager	This command configures the IoT manager settings.

Command History

Release	Modification
ArubaOS 8.7.0.0	The <code>ble-services</code> parameter was added.
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show ip

```
show ip
  access-group
  access-list
  cp-redirect-address
  dhcp
  domain-name
  dynamic-dns
  health-check
  igmp
  interface
  mobile
  nat
  nexthop-list
  ospf
  pppoe-info
  probe
  radius
  route
  tacacs
```

Description

Displays IP related details.

Parameter	Description
<u>access-group</u>	Displays ACLs configured for each port on Mobility Conductor.
<u>access-list</u>	Displays a table of all configured ACLs, or show details for a specific ACL.
<u>cp-redirect-address</u>	Show the captive portal automatic redirect IP address.
<u>dhcp</u>	Displays the DHCP server binding, database setting, relay and pool statistics.
<u>domain-name</u>	Displays the full domain name and server.
<u>dynamic-dns</u>	Displays the dynamic DNS details.
<u>health-check</u>	Displays the health-check status of the uplink interfaces of a branch office managed device.
<u>igmp</u>	Displays IGMP timers and counters.
<u>interface</u>	IP interface information

Parameter	Description
mobile	Displays statistics and configuration information for the mobile protocol.
nat	Displays a pool of IP addresses for NAT.
nexthop-list	Displays the next hop list settings for policy-based routing. A next hop IP is the IP address of a adjacent router or device with layer-2 connectivity to managed device.
ospf	Displays statistics and configuration information for the OSPF routing protocol.
pppoe-info	Displays the configuration settings for PPPoE.
probe	Displays the health-check profile settings for measuring WAN reachability and latency on a managed device uplink, and the default probe profile settings for PBR using next-hop lists.
radius	Displays global parameters for configured RADIUS servers.
route	Displays the Mobility Conductor routing table with static routes configured on the Mobility Conductor using the ip route command.
tacacs	Displays global parameters for configured TACACS servers.

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ip access-group

show ip access-group

Description

Displays ACLs configured for each port on Mobility Conductor.

Examples

The example below shows part of the output of this command. If a port does not have a defined session ACL, the *Port-Vlan Session ACL* table will be blank.

```
(host) [mynode] #show ip access-group

FE 1/0:
Rx access list 200 is applied
session access list User14 is applied

Port-Vlan Session ACL
-----
SessionACL          Vlan      Status
-----
coltrane             22        configured
```

The output of this command includes the following parameters:

Parameter	Description
Session ACL	Name of the ACL applied to the interface.
VLAN	If the ACL was applied to a VLAN associated with this port, this column will show the VLAN ID.
Status	Shows whether or not the session ACL is configured.

Related Commands

Command	Description
ip access-group	Configures an access group for an interface.

Command History

show ip access-list

```
show ip access-list
  brief [ipv4|ipv6]
  <string>
  global-geolocation-acl
```

Description

This command displays a table of all configured ACLs, or show details for a specific ACL.

Parameter	Description
brief	Display a table of information for all ACLs.
<string>	Specify the name of a single ACL to display detailed information on that ACL.
global-geolocation-acl	Displays configured values of the global-geolocation-acl ACL.

Examples

The example below shows general information for all ACLs in the Access List table.

```
(host) [mynode] #show ip access-list brief

Access list table (4 - IPv4, 6 - IPv6)
-----

captiveportal6                     session(6)          2          guest-logon logon
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of an ACL.
Type	Shows that the ACL is one of the following ACL policy types: <ul style="list-style-type: none"> ■ Ethertype ■ Standard ■ Session ■ MAC ■ Extended
Use Count	Number of rules defined in the ACL.
Roles	Names of user roles associated with the ACL.

Include the name of a specific ACL to show detailed configuration information for that ACL. The output in the example below has been divided into two sections to better fit into this document. The output in the CLI will appear in a single, long table.

```
(host) [mynode] # show ip access-list captiveportal6

ip access-list session captiveportal6

```

The following parameters are used specifically for the bridge mode:

```
show ip access-list captiveportalbridge
show ip access-list logon-control-bridge
```

The output of the `show ip access-list` command may include some or all of the following parameters:

Parameter	Description
Priority	Name of an access-control list (ACL).
Source	<p>The traffic source, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ alias: The network resource (use the <code>netdestination</code> command to configure aliases; use the <code>show netdestination</code> command to see configured aliases) ▪ any: Matches any traffic. ▪ host: A single host IP address. ▪ network: The IP address and netmask. ▪ user: The IP address of the user. ▪ localip: The set of all local IP addresses on the system, on which the ACL is applied.
Destination	<p>The traffic destination, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ alias: The network resource (use the <code>netdestination</code> command to configure aliases; use the <code>show netdestination</code> command to see configured aliases) ▪ any: Matches any traffic. ▪ host: A single host IP address. ▪ network: An IP address and netmask. ▪ user: The IP address of the user. ▪ localip: The set of all local IP addresses on the system, on which the ACL is applied.
Service	<p>Network service, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ An IP protocol number (0-255). ▪ The name of a network service (use the <code>show netservice</code> command to see configured services). ▪ any: Matches any traffic. ▪ tcp: A TCP port number (0-65535). ▪ destination port number: specify the TCP port number (0-65535) ▪ source: TCP or UDP source port number ▪ udp: A UDP port number (0-65535).

Parameter	Description
Application	Name of the application to which the ACL is applied. (For a complete list of supported applications, issue the command <code>show dpi application all</code> .)
Action	Action if rule is applied, which can be one of the following: <ul style="list-style-type: none"> ▪ deny: Reject packets. ▪ dst-nat: Perform destination NAT on packets. ▪ dual-nat: Perform both source and destination NAT on packets. ▪ permit: Forward packets. ▪ redirect: Specify the location to which packets are redirected, which can be one of the following: <ul style="list-style-type: none"> ◦ Datapath destination ID (0-65535). ◦ esi-group: Specify the ESI server group configured with the <code>esi group</code> command ◦ opcode: Specify the datapath destination ID (0x33, 0x34, or 0x82). Do not use this parameter without proper guidance from Aruba. ▪ tunnel: Specify the ID of the tunnel configured with the <code>interface tunnel</code> command. ▪ src-nat: Perform source NAT on packets.
IpssecMap	Packets can be redirected over a VPN tunnel by specifying the name of an IPsec map in the ACL. This column specifies the name of an IPsec map used by a router ACL. For more information on IPsec maps, see crypto-local ipsec-map .
Timerange	Any defined time range for this rule.
NextHopList	If the access rule uses PBR to forwards packets to a nexthop device, then this column displays the next-hop list associated with the rule. For more information on next-hop lists, see ip nexthop-list on page 871 .
Tunnel	Packets can be redirected over an L3 GRE tunnel. If the ACL routes packets over a tunnel, this column specifies the tunnel used by the ACL.
TunnelGroup	Packets can be redirected over an L3 GRE tunnel group. If the ACL routes packets over a tunnel in a tunnel group, this column specifies the tunnel group used by the ACL. For more information on tunnel groups, see tunnel-group .
Log	Shows if the rule was configured to generate a log message when the rule is applied.
Expired	Shows if the rule has expired.

Parameter	Description
Queue	Shows if the rule assigns a matching flow to a priority queue (high or low).
8021.p	802.11p priority level applied by the rule (0-7).
Blacklist/Denylist	Shows if the rule should blacklist/denylist any matching user.
Mirror	Shows if the rule was configured to mirror all session packets to datapath or remote destination.
DisScan	Shows if the rule was configured to pause ARM scanning while traffic is present.
IPv4/6	Shows the IP version.
Contract	Shows the bandwidth contract status.

Related Commands

show ip cp-redirect-address

show ip cp-redirect-address

Description

Show the captive portal automatic redirect IP address.

Examples

The example below shows the IP address to which captive portal users are automatically directed.

```
(host) [mynode] # show ip cp-redirect-address  
  
Captive Portal IPv4 redirect Address ... 10.3.63.11  
Captive Portal IPv6 redirect Address ... ::1
```

Related Commands

Command	Description
ip cp-redirect-address	This command configures a redirect address for captive portal.

Command History

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ip dhcp

```
show ip dhcp
  binding
  database
  option-82
  relay counters
  reserved
  statistics
  vlan
```

Description

This command displays the DHCP server binding, database setting, relay, pool statistics, and device reservations.

Parameter	Description
binding	Show DHCP server bindings.
failover-peer	Show DHCP server failover peer bindings.
ip-address	Show DHCP server binding for IP address.
mac-address	Show DHCP server bindings.
database	Show DHCP server settings.
option-82	Show DHCP option-82 configurations.
relay counters	Show DHCP relay information.
reserved	Show DHCP server device reservations.
statistics	Show DHCP pool statistics.
vlan	Show DHCP vlan information.

Examples

The following example displays DHCP statistics for two configured networks:

```
(host) [mynode] #show ip dhcp statistics

DHCPv4 enabled; DHCPv6 enabled
DHCP Pools
-----
```

Network Name	Type	Active	Configured leases	Active leases	Free leases
2-2-2-nw	v4	Yes	242	0	242
3-2-2-nw	v4	Yes	254	0	254
test	v4	Yes	254	0	254
2011	v6	No	5	-	-
2012	v6	No	5	-	-
Current leases		750			
Total leases		512			

Starting from ArubaOS 8.2.0.0, if the DHCP lease limit is configured to exceed the user limit, a warning is displayed in the command output.

```

host) (config) #show ip dhcp statistics
DHCPv4 disabled; DHCPv6 disabled
DHCP Pools
-----
Network Name  Type  Active  Configured leases  Active leases  Free leases
Expired leases
-----
Abandoned leases
-----
Current leases      0
Total leases      2048
WARNING: DHCP lease limit increased beyond user limit. Some of the controller's services may be impacted
NOTE: To make a DHCPv6 pool active, ensure that the pool name is added in
vlan interface.

```

The output of this command includes the following parameters:

Parameter	Description
Network Name	Range of addresses that the DHCP server may assign to clients.
Type	Indicates the IP version of the DHCP server. It can be v4 or v6.
Active	Indicates if the DHCP server is active or not.
Configured leases	Number of leases configured on the DHCP server.

Parameter	Description
Active leases	Number of active DHCP leases.
Free leases	Number of available DHCP leases.
Expired leases	Number of leases that have expired because they have extended past their valid lease period.
Abandoned leases	Number of abandoned leases. Abandoned leases will not be reassigned unless there are no free leases available.

The following example displays information about DHCP server device reservations:

```
(host) [mynode] (config) #show ip dhcp reserved
DHCP Server Device Reservation Information
-----
Hardware Address  Reserved IP Address  Hostname  Lease Status
-----
00:1A:1E:C0:80:28  10.3.129.253
00:0B:86:42:35:80  10.3.129.99
00:1A:1E:C0:1C:60  10.3.129.254        print    CONNECTED
```

The output of this command includes the following parameters:

Parameter	Description
Hardware Address	Indicates the MAC address of the client device.
Reserved IP Address	Indicates the IP addresses manually reserved from a DHCP pool.
Hostname	Indicates the hostname of the client device.
Lease Status	Indicates whether the client received the IP address or not. This parameter displays one of the following values: <ul style="list-style-type: none"> ■ Connected ■ Disconnected <p>NOTE: The Lease Status displays Connected after a successful DHCP negotiation, when the client receives an IP address from the reserved list. The Lease Status displays Disconnected when the IP address is not assigned to the client.</p>

show ip health-check

```
show ip health-check <probe-ip> <src_intf>
```

Description

This command displays the health-check status of the uplink interfaces of a branch office managed device. This command must be executed from the branch office managed device.

Parameter	Description
debug	Displays health-check debug information.
nhinfo	Displays uplink nexthop information.
proberef	Displays uplink probe profile reference list.
verbose	Displays detailed statistics for IP health-check information.
<probe-ip>	IP address of Mobility Conductor.
<src_intf>	Source interface VLAN.

Example

The following example displays the status of two uplinks on a branch office managed device.

```
(host-md) #show ip health-check

IP Health-check Entries
-----

Probe IP          Src Interface  Vpnc IP      State  Probe-Profile
Latency(ms)      Jitter  Loss(%)      MOS
-----
-----
9.9.9.9           vlan 4093                Up    health-check-default
44.400           0
5.5.5.21         vlan 4093      182.72.28.53  Up    data-vpnc
10.000           0.000  0             4.4
10.17.126.161                0             Up    default
0.000
-----
Total Entries: 3
```

The output of this command includes the following data columns.

Parameter	Description
Probe IP	IP address of Mobility Conductor.
Src Interface	IP address of the uplink gateway interface through which the probes were sent.
VPNC IP	Displays the VPN client IP address.
State	Displays the uplink state as either UP or DOWN.
Probe-Profile	Displays the name of the IP probe profile. For information on configuring an IP probe profile, see ip probe default
Latency (ms)	Displays the latency in ms. Latency is calculated based on the delay of ping responses.
Jitter	Displays the jitters in packet flow. Jitter is a variation in the delay of received packets, which can be worsened by network congestion, improper queuing and configuration errors.
Loss (%)	Displays the data packet loss in percentage.
MOS	Displays the estimated Mean Opinion Score.

Related Commands

  interface [vlan <vlan>]
  proxy-group [vlan <vlan>]
  proxy-mobility-group maddr <maddr>
  proxy-mobility-stats
  proxy-stats
```

Description

This command displays IGMP timers and counters.

Parameter	Description
cluster	See show ip igmp cluster .
config	Show the current IGMP configuration
counters	Display a list counters for the following IGMP queries: <ul style="list-style-type: none">received-totalreceived-queriesreceived-v1-reportsreceived-v2-reportsreceived-leavesreceived-unknown-typeslen-errorschecksum-errorsnot-vlan-drtransmitted-queriesforwarded
group maddr <maddr>	Displays the following IGMP group information: <ul style="list-style-type: none">mac: Specify MAC address of the specific member.source: Specify the source address of the specific SSM group.
interface vlan <vlan>	Show IGMP interface information
proxy-group vlan <vlan>	Show IGMP proxy group information for a specific interface.

Parameter	Description
proxy-mobility-group maddr <maddr>	Display the IGMP proxy group information stored for mobile clients which are away from the managed device.
proxy-mobility-stats	Display the most important messages exchanged between the mobility process and the IGMP proxy.
proxy-stats	Display the number of messages transmitted and received by the IGMP proxy on the upstream interface

Examples

The following example displays the IGMP interface table for all VLANs on Mobility Conductor.

```
(host) [mynode] #show ip igmp interface vlan 2

IGMP Interface Table
-----
VLAN  Addr          Netmask          MAC Address      IGMP      Snooping
Querier  Destination IGMP Proxy

63    10.6.3.252  255.255.255.0  00:0b:86:01:99:00  disabled  disabled
10.6.3.252 CP          disabled
```

The output of this command includes the following parameters:

Parameter	Description
VLAN	A VLAN ID number.
Addr	IP address of a VLAN router.
Netmask	Subnet mask for the IP address.
MAC Address	MAC destination address.
IGMP	Indicates if IGMP is enabled (or disabled) on the interface.
Snooping	Indicates if IGMP snooping is enabled (or disabled).

Parameter	Description
Querier	IP address of an IGMP querier.
Destination	Traffic destination.
IGMP Proxy	Indicates if IGMP proxy is enabled (or disabled).

The following example displays the current IGMP configuration settings for Mobility Conductor.

```
(host) [mynode] #show ip igmp config

IGMP Config
-----
Name                               Value
----                               -
robustness-variable                2
query-interval                     30
query-response-interval            100
startup-query-interval             31
startup-query-count                2
last-member-query-interval         10
last-member-query-count            2
version-1-router-present-timeout   400
version-2-router-present-timeout   400
max-members-per-group              300
quick-client-convergence            enabled
ssm-range                          IANA standard range. 232.0.0.0/8
```

The output of this command includes the following parameters:

Parameter	Description
robustness-variable	This variable is increased from its default level of 2 to allow for expected packet loss on a subnetwork.
query-interval	Interval, in seconds, at which Mobility Conductor sends host-query messages to the multicast group address 224.0.0.1 to solicit group membership information.
query-response-interval	Maximum time, in .1 second intervals, that can elapse between when Mobility Conductor sends a host-query message and when it receives a response. This must be less than the <code>query-interval</code> .
startup-query-count	Number of queries that Mobility Conductor sends out on startup, separated by <code>startup-query-interval</code> . The default setting is the value of the <code>robustness-variable</code> parameter.

Parameter	Description
startup-query-interval	Interval, in seconds, at which Mobility Conductor sends general queries on startup. The default value of this parameter is 1/4 of the query-interval.
last-member-query-count	Number of group-specific queries that Mobility Conductor sends before assuming that there are no local group members.
last-member-query-interval	Maximum time, in seconds, that can elapse between group-specific query messages.
version-1-router-present-timeout	Timeout, in seconds, if Mobility Conductor detects a version 1 IGM router.
version-2-router-present-timeout	Timeout, in seconds, if Mobility Conductor detects a version 2 IGM router.

The following examples displays the information on IGMP groups:

```
(host) [mynode] #show ip igmp group

```
show ip interface brief
```

Description

This command displays the IP-related information on all interfaces in summary format.

Example

```
(host) #show ip interface brief
Interface                IP Address / IP Netmask      Admin  Protocol
VRRP-IP
vlan 1                   172.16.0.254 / 255.255.255.0  up     up
vlan 2                   10.4.62.9 / 255.255.255.0    up     up
loopback                 unassigned / unassigned      up     up
mgmt                    unassigned / unassigned      down   down
```

The following table details the columns and content in the show command.

Column	Description
Interface	List the interface and interface identification, where applicable.
IP Address /IP Netmask	List the IP address and netmask for the interface, if configured.
Admin	States the administrative status of the interface. Enabled—up Disabled—down
Protocol	Status of the IP on the interface. Enabled—up Disabled—down
VRRP-IP	VRRP IP address associated to the interface.

  traffic dropped|foreign-agent|home-agent|proxy
  trail <host-ip>|<host-ipv6><host-macaddr>
  tunnel
  visitor [<host-ip>|<host-ipv6>|<host-macaddr>|brief]
```

Description

This command displays statistics and configuration information for the mobile protocol.

Parameter	Description
act	Active anchor managed device table; subnets to another managed device map.
active domains	IP mobility domains active on this switch
binding	Display a list of Home Agent Bindings
[<host-ip>]	Filter the Home Agent Bindings list to display data for a specific host IPv4 address.
[<host-ipv6>]	Filter the Home Agent Bindings list to display data for a specific host IPv6 address.
[<host-macaddr>]	Filter the Home Agent Bindings list to display data for a specific host MAC address.
[brief]	Limit the output of this command to show just two lines of data.
domain [<name>]	Display subnet, VLAN, and home agent information for all mobility domains, or specify a mobility domain name to view data for that domain only.
global	View the current Mobility Agents global configuration

Parameter	Description
hat	Display the active Home Agent table
host	Display a list of Mobile IP hosts.
[<host-ip>]	Filter the Mobile Host List to display data for a specific host IPv4 address.
[<host-ipv6>]	Filter the Mobile Host List to display data for a specific host IPv6 address.
[<host-macaddr>]	Filter the Mobile Host List to display data for a specific host MAC address.
[brief]	Limit the output of this command to show just two lines of data.
multicast-vlan-table	Displays mobility multicast VLAN table information.
mac	MAC address of the client.
packet-trace [<count>]	The output of this command shows when packets of different types were sent between a source IP or MAC address and a destination IP or MAC address.
remote <host-ip> <host-ipv6> <host-macaddr>	This is a debug command can be used to identify the managed device associated with the specified client IPv4 or IPv6 address or MAC address. The output of this command shows the home agent (HA) and foreign agent (FA) for a mobile client, as well as the client's roaming status.
trace	Show if the Mobile IP feature will poll remote managed device for mobility status of station.
<host-ip>	Host IPv4 address.
<host-ipv6>	Host IPv6 address.
<mac-addr>	Host MAC address
force <host-ip> <host-ipv6> <mac-addr>	Show if the Mobile IP feature will poll remote managed device for mobility status of station.
traffic	Display mobile IP protocol statistics for: <ul style="list-style-type: none"> ■ Proxy Mobile IP ■ Home Agent Registrations ■ Foreign Agent Registrations ■ Registration Revocations
dropped	Show only counters for dropped mobility traffic.
foreign-agent	Show only mobile IP foreign agent statistics.

Parameter	Description
	A foreign agent is the managed device which handles all mobile IP communication with a home agent on behalf of a roaming client.
home-agent	Show only mobile IP home agent statistics. A home agent for a mobile client is the managed device where the client first appears when it joins the mobility domain.
proxy	Show only counters for mobile IP proxy traffic.
trail <host-ip> <host-ipv6> <host-macaddr>	Show the mobile IP roaming trail by entering a host's IP (IPv4 or IPv6) or MAC address.
tunnel	Show the Mobile Tunnel Table for IPIP tunnels.
visitor	Display a list of mobile nodes visiting a foreign agent.
[<host-ip>]	Filter the Foreign Agent Visitor list to display data for a specific host IPv4 address.
[<host-ipv6>]	Filter the Foreign Agent Visitor list to display data for a specific host IPv6 address.
[<host-macaddr>]	Filter the Foreign Agent Visitor list to display data for a specific host MAC address.
[brief]	Limit the output of this command to show just two lines of data.

Examples

The example below lists mobility domains configured on the managed device, and shows information for any subnets defined on these domains.

```
(host) [mynode] #show ip mobile domain

Mobility Domains:, 2 domain(s)
-----

Domain name default
  Home Agent Table, 0 subnet(s)

Domain name newdomain
  Home Agent Table, 2 subnet(s)
  subnet          mask          VlanId Home Agent      Description
  -----
-----
  10.2.124.76     255.255.255.255 1      10.4.62.2              Corporate
mobility entry
```

172.21.5.50 255.255.255.255 1 10.4.62.2 Reserved entries

The output of this command includes the following parameters:

Parameter	Description
Home Agent	IP address of the home agent or mobility agent.
Description	Description of the HAT entry.

Use the `show ip mobile host` command to track mobile users.

```
(host) [mynode] #show ip mobile host

Mobile Host List, 1 host(s)
-----
9c:b7:0d:3f:a6:dd 10.16.23.219  mob1
IPv4: 10.16.23.219
IPv6: fe80::826:aa9a:fe35:53e0
2004:deed::34
Roaming Status: Home Switch/Home VLAN, Service time 0 days 01:34:19
Home VLAN 623 on network 10.16.23.0/24
DHCP lease for PC at Sun Dec 23 20:32:00 2012 for 86400 secs from 10.16.28.1
```

The output of this command includes the following parameters:

Parameter	Description
<mac-addr> <ip-addr>	MAC and IP addresses of the host
Roaming Status	Displays how long the host has used its current managed device and VLAN.
Home VLAN	VLAN ID, IP address and subnet of the home VLAN.
DHCP lease	Displays the amount of time the station has had its current DHCP lease.

show ip nat pool

```
show ip nat pool
```

Description

This command displays a pool of IP addresses for NAT.

Examples

The example below shows the current NAT pool configuration on Mobility Conductor.

```
(host) [mynode]# show ip nat pools

NAT Pools
-----
Name   Start IP      End IP         DNAT IP       Flags
----   -
2net   192.0.2.2     192.0.2.48    192.0.2.222
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the NAT pool.
Start IP	IP address that defines the beginning of the range of source NAT addresses in the pool.
End IP	IP address that defines the end of the range of source NAT addresses in the pool.
DNAT IP	Destination NAT IP address, if defined.
Flags	NAT pool flags, if any.

show ip nexthop-list

```
show ip nexthop-list
  details STRING
  STRING
```

Description

This command displays the next hop list settings for policy-based routing. A next hop IP is the IP address of a adjacent router or device with layer-2 connectivity to managed device. The next hop list provides redundancy for the next hop devices by forwarding the traffic to a backup next hop device in case of failures. If active next hop device on the list becomes unreachable, traffic matching a policy-based routing ACL is forwarded using the highest-priority active next hop on the list. For more information on this feature, see [ip nexthop-list on page 871](#).

Parameter	Description
details	Displays detailed next hop settings for policy-based routing.
STRING	Displays the next hop settings based on the next hop list name.

Example

The following command displays the configuration settings for the one configured next hop list.

```
(host) [mynode] #show ip nexthop-list

Flags: N - Nexthop SLA non-compliant

Nexthop-List Entries
-----
Name          Dest  Preemptive Failover  Nexthop          Nexthop
Dest  Nexthop Priority  Wan Health-Check probe  SLA Profile
----  -
-----
load-balance-gateways          Enabled
load-balance-ipsecs           Enabled
pan-gp-ipsec-map-list         Enabled
test_nhl                       Enabled          145.145.145.10
  128                          Disabled
traditional-ipsecs            Enabled
```

The output of this command displays the following information

Parameter	Description
Name	Name of the next hop list
Dest	Destination prefix address.
Preemptive Failover	This column indicates whether preemptive failover is enabled or disabled. If preemption is enabled and a higher priority next hop becomes reachable again, packets are again forwarded to the higher priority next hop.
Nexthop	Next hop IP address.
Nexthop Dest	Next hop destination prefix address.
Nexthop Priority	List of the IP addresses of all next hop IPs, including the priority assigned to each device when the list was configured.
Wan Health-Check probe	Indicates weather the next hop failover is enabled or disabled.
SLA profile	Displays name of the IP-SLA profile configured to the next hop.

Related Commands

Command	Description
ip route	This command configures a static route on Mobility Conductor. (These routes can use a next hop list.)
ip nexthop-list	Configure next hop list settings for policy-based routing.

Command History

Version	Description
ArubaOS 8.0.0.0	Command introduced.

show ip ospf

```
show ip ospf
  database area <area-id>
  debug route
  ike-overlay aggregate-routes <addr>
  interface [tunnel|vlan] <id>
  neighbor
  rapng-vpn aggregate-routes <ip-addr> <mask>
  redistribute
  static aggregate-routes <addr>
  subnet
```

Description

Display statistics and configuration information for the OSPF routing protocol.

Parameter	Description
database area <area-id>	Show database information for the OSPF protocol.
debug route	Show debugging information for OSPF routes.
ike-overlay aggregate-routes <addr>	Show Ike overlay aggregate information for OSPF routes.
interface [tunnel vlan] <id>	Display the status of OSPF on an individual interface by specifying a tunnel or VLAN ID number. The tunnel ID range is 1-16777215.
neighbor	Display data for OSPF neighboring routers.
rapng-vpn	Display IAP-VPN information.
aggregate-routes <ip-addr> <mask>	Display IAP-VPN aggregate route information.
redistribute	Display OSPF route distribution information.
static aggregate-routes <addr>	Display STATIC Aggregate routes information.
subnet	Display the subnets manually added to the Subnet Exclude List via the router ospfsubnet exclude <addr> <mask> command.

Example

If you issue this command without any of the optional parameters described in the table above, the `show ip ospf` command will display general router and area settings for the OSPF.

```
(host) [mynode] #show ip ospf

OSPF is currently running with Router ID 123.45.110.200
Number of areas in this router is 1
Area 10.1.1.0
    Number of interfaces in this area is 2
    Area is totally stub area
    SPF algorithm executed 0 times
```

The output of this command includes the following parameters.

Parameter	Description
OSPF Router ID	Verifies that OSPF is running and the router ID that OSPF is running on.
Number of areas	List the number of areas configured in the router.
Area	Displays the Area ID followed by: <ul style="list-style-type: none"> ■ number of interfaces in the area ■ indicates if the area is a totally stub area ■ number of times the SPF algorithm has been executed

To display OSPF settings for an individual interface, you must specify a VLAN or tunnel ID number. The example below displays part of the output of the `show ip ospf interface vlan` command.

```
(host) [mynode] #show ip ospf interface vlan 1

Vlan 1 is up, line protocol is up
Internet Address 170.1.0.1, Mask 255.255.255.0, Area 2.0.1.1
Router ID 16.1.0.2, Network Type BROADCAST, Cost: 1
Transmit Delay is 1 sec, State DROTHER, Priority 0
Designated Router id 0.0.0.0, Interface Address 170.1.0.1
Backup designated Router id 0.0.0.0, Interface Address 170.1.0.1
Timer intervals configured, Hello 10, Dead 40, Retransmit 5
Neighbor Count is 0
Tx Stat: Hellos 7 DbDescr 0 LsReq 0 LsUpdate 0 LsAck 0 Pkts 7
Tx Err: BufNull 0 BufCorrupt 0 NoMem 0 SendFail 0
Rx Stat: Hellos 0 DbDescr 0 LsReq 0 LsUpdate 0 LsAck 0 Pkts 0
LoopSend 0 RxVirtualLink 0
Rx Err: DisCd 0 BadVer 0 BadNet 0 BadArea 0 BadDstAdr 0 BadAuType 0
BadAuth 0 BadNeigh 0 BadPckType 0 BadVirtLink 0
IntfDown 0 MySource 0 Legal 0
```

...

The output may include some or all of the following parameters.

Parameter	Description
Vlan <number>	Identifies that the interface type and ID are up and functional.
Internet Address	Internet address, network mask, and area assigned to the interface.
Router ID	Displays the router ID, that the network type is Broadcast, and the cost value.
Transmit Delay	Details of the transmit delay, state, and priority.
Designated Router	Details of the designated router ID and interface address.
Backup Designated Router ID	Details of the backup router ID and interface address.
Timer intervals configured	Details of elapse time intervals for Hello, Dead, Transmit (wait), and retransmit.
Neighbor Count	Details the number of neighbors and adjacent neighbors.
Tx Stat	Counters and statistics for transmitted data. <ul style="list-style-type: none"> ▪ Hellos: Number of transmitted hello packets. These packets are sent every hello interval. ▪ DbDescr: Number of transmitted database description packets. ▪ LsReq: Number of transmitted link state request packets. ▪ LsUpdate: Number of transmitted link state update packets. ▪ LsAck: Number of transmitted link state acknowledgment packets ▪ Pkts: Total number of transmitted packets.
Tx Err	Counters and statistics for received data. <ul style="list-style-type: none"> ▪ Hellos: Number of received hello packets. These packets are sent every hello interval. ▪ DbDescr: Number of received database description packets. ▪ LsReq: Number of received link state request packets. ▪ LsUpdate: Number of received link state update packets. ▪ LsAck: Number of received link state acknowledgment packets ▪ Pkts: Total number of received packets.
Rx Stat	Counters and statistics for received data. <ul style="list-style-type: none"> ▪ Hellos: Number of received hello packets. These packets are sent every hello interval. ▪ DbDescr: Number of received database description packets.

Parameter	Description
	<ul style="list-style-type: none"> ▪ LsReq: Number of received link state request packets. ▪ LsUpdate: Number of received link state update packets. ▪ LsAck: Number of received link state acknowledgment packets ▪ Pkts: Total number of received packets.
Rx Err	<p>Counters and statistics for received data.</p> <ul style="list-style-type: none"> ▪ Hellos: Number of received hello packets. These packets are sent every hello interval. ▪ DbDescr: Number of received database description packets. ▪ LsReq: Number of received link state request packets. ▪ LsUpdate: Number of received link state update packets. ▪ LsAck: Number of received link state acknowledgment packets ▪ Pkts: Total number of received packets.
DisCd	Number of received packets that are discarded.
BadVer	Number of received packets that have bad OSPF version number.
BadNet	Number of received packets that belong to different network than the local interface.
BadArea	Number of received packets that belong to different area than the local interface.
BadDstAdr	Number of received packets that have wrong destination address.
BadAuType	Number of received packets that have different authentication type than the local interface.
BadAuth	Number of received packets where authentication failed.
BadNeigh	Number of received packets which didn't have a valid neighbor.

show ip pppoe-info

```
show ip pppoe-info
```

Description

This command displays the configuration settings for PPPoE.

Examples

The following example displays the current PPPoE configuration.

```
(host) [mynode] #show ip pppoe-info

PPPoE username: rudolph123
PPPoE password: <HIDDEN>
PPPoE service name: ppp2056
PPPoE VLAN: 22
Gateway NAT: Enabled
IP: 10.1.1.1
PPPoE is UP
Server IP: 9.0.0.3
Gateway IP: 9.0.0.3
Primary DNS: <NONE> Secondary DNS: <NONE>
```

The output of this command includes the following parameters:

Parameter	Description
PPPoE username	PAP username configured on the PPPoE access concentrator.
PPPoE password	If this parameter displays the word <HIDDEN> , a PAP password is configured on the PPPoE access concentrator. If this parameter is <NONE> , there is no PPPoE password configured.
PPPoE service name	PPPoE service name.
PPPoE VLAN	VLAN configured to use PPPoE to obtain an IP address via the command <code>interface vlan <id> ip address pppoe</code> .

Related Commands

Command	Description

show ip probe

```
show ip probe
```

Description

This command displays the **health-check** profile settings for measuring WAN reachability and latency on a managed device uplink, and the **default** probe profile settings for PBR using next-hop lists.

The health-check feature uses ping or UDP probes for measuring WAN reachability and latency. PBR routing uses ping probes to determine the reachability of devices on a next-hop list. This command must be executed from the managed device only.

Examples

The following command displays the current IP probe settings for the **default** and **health-check** IP probe profiles.

```
(host-md) #show ip probe

IP Probe Entries
-----
Name           Probe Mode  Frequency(in sec)  Retries  Burst size
-----
default        Ping        10                 19       3
health-check   Ping        10                 3        5
```

The output of this command contains the following information:

Column	Description
Name	Name of the ip probe profile, which is either default or health-check .
Probe Mode	Indicates whether the probes are sent as ping or UDP packets.
Frequency	Probe interval, in seconds. The managed device sends the number of probes in the Burst Size column during each frequency interval.
Retries	Number of times the managed device attempts to resend a probe.
Burst size	Number of probes sent during the probe frequency interval that appears in the Frequency column.

Related Commands

Command	Description
ip probe default	This command configures IP probes for PBR using a next-hop list.
ip probe health-check	This command configures WAN health-check ping-probes for measuring WAN availability and latency on managed device uplinks.

show ip radius

```
show ip radius
  nas-ip
  source-interface
```

Description

This command displays global parameters for configured RADIUS servers.

Parameter	Description
nas-ip	Show the Network Access Server (NAS) IP address attribute sent in outgoing RADIUS requests.
source-interface	Show the source interface address of outgoing RADIUS requests.

Examples

The following example displays the RADIUS client NAS IP address:

```
(host) [mynode] #show ip radius nas-ip
RADIUS client NAS IP address = 10.168.254.221
RADIUS client NAS IPv6 address = ::1
```

The following example displays the RADIUS client source interface address of the outgoing RADIUS requests:

```
(host) [mynode] #show ip radius source-interface
Global radius client source IP address = 12.0.2.26, vlan 3
Global radius client source IPv6 address = ::, vlan 0
Per-server client source IPv4/6 addresses:
```

Related Commands

show ip route

```
show ip route
  counters
  ike-overlay
  sdwan
  static
  stats
  verbose
```

Description

This command displays the Mobility Conductor routing table with static routes configured on the Mobility Conductor using the [ip route](#) command. Use the [ip default-gateway](#) command to set the default gateway to the IP address of the interface on the upstream router or switch to which you connect Mobility Conductor.

Starting from ArubaOS 8.11.0.0, you can use the `ip default-gateway mgmt <nextthop>` command to configure the default gateway on the OOB management port for 7000 Series controllers.

Parameter	Description
counters	Displays the number of routes present, categorized by type.
ike-overlay	Displays ike-overlay routes.
sdwan	Displays sdwan routes.
static	Include this optional parameter to display only static routes.
stats	Displays route statistics.
verbose	Displays verbose information about routes.

Examples

The following example displays the IP address of routers and the VLANs to which they are connected:

```
(host) [mynode]#show ip route
M - mgmt, U - route usable, * - candidate default, V - RAPNG VPN/Branch
Gateway of last resort is Imported from DHCP to network 0.0.0.0 at cost 10
Gateway of last resort is Imported from CELL to network 0.0.0.0 at cost 10
Gateway of last resort is Imported from PPPOE to network 0.0.0.0 at cost 10
Gateway of last resort is 10.7.73.77 to network 0.0.0.0 at cost 1
S*   0.0.0.0/0   [1/0] via 10.7.73.77*
S    172.0.0.0/8 [1/0] via 172.16.1.253*
```

Related Commands

Command	Description

show ip tacacs

```
show ip tacacs
  source-interface
```

Description

This command displays global parameters for configured TACACS servers. The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
<code>source-interface</code>	Shows the source interface address of outgoing TACACS requests.

Examples

The following example displays the TACACS client source interface address of the outgoing TACACS requests:

```
(host) [mynode] #show ip tacacs source-interface
Global tacacs client source IP address = 0.0.0.0, vlan 0
Global tacacs client source IPv6 address = ::, vlan 0
Per-server client source IPv4/6 addresses:
```

show ip-flow-export

```
show ip-flow-export
  collector [<ipaddr>]
  gsm-cache
```

Description

This command shows information for IP flow collector and the GSM cache.

Parameter	Description
collector [<ipaddr>]	Specify the IP address of the collector.
gsm-cache	Shows GSM cache.

Example

The following command displays information about the IP flow collector.

```
(host) [mynode] #ip-flow-export collector

Observation Domain: 168096376 (Controller IP)
Collector IP Not Configured, protocol udp, port 4739, not enabled, not
connected
Upload template always, upload all sessions every 15 minute(s), no upload
flow cache snapshot
15000 flow cache size, 0 flows exported, next sequence 0, 0 packets, 0 bytes
Last template send: Never, last dispatch: Never
0 Connect errors, 0 connection resets, 0 send errors, 0 flows dropped, 0
blocked sends
(RJ_LC120) #show ip-flow-export collector 1.1.1.1
Observation Domain: 168096376 (Controller IP)
Collector IP 1.1.1.1, protocol udp, port 4739, not enabled, not connected
Upload template always, upload all sessions every 15 minute(s), no upload
flow cache snapshot
15000 flow cache size, 0 flows exported, next sequence 0, 0 packets, 0 bytes

show ip-flow-export-profile

show ip-flow-export-profile

Description

This command shows the stats for IP flow collector profile.

Example

The following command displays details for the IP flow export profile

```
(host) [mynode] #show ip-flow-export-profile

IP Flow Collector Profile
-----
Parameter                               Value      Set
-----
State                                    Disabled
Interval (minutes) to upload all active sessions 15
Interval (minutes) to upload cache snapshot      0
Interval (minutes) to upload IPFIX template     0
Transport Protocol for collector connection     udp
IPFIX Collector IP address                     N/A
Transport Port for collector connection        4739
Flow Cache size in entries                     15000
Observation Domain                            0
```

show ipc statistics

```
show ipc statistics
  app-ap
  app-id
  app-name
```

Description

This command displays the Inter Process Communication (IPC) statistics.

Parameter	Description
app-ap	Displays the Inter Process Communication (IPC) statistics for a specific AP or BSSID.
app-id	Application ID number. This number must be obtained from Aruba TAC.
app-name	Displays Inter Process Communication (IPC) statistics for a specific application.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show ipc statistics app-ap

```
show ipc statistics app-ap {am|ap-stm|ofald|sapd}
  ap-name <ap-name>
  bssid <bssid>
  ip-addr <ip-addr>
```

Description

This command displays the Inter Process Communication (IPC) statistics for a specific AP or BSSID. Execute this command under the supervision of Aruba TAC to troubleshoot application errors. This command must be executed on a standby controller or managed device where the APs terminate.

Parameter	Description
am	Show IPC statistics for an air monitor.
ap-stm	Show IPC statistics for AP station management communication.
ofald	OpenFlow Agent Lite Daemon. Show OpenFlow Agent statistics running on the AP.
sapd	Show IPC statistics for the AP management process on the AP.
ap-name <ap-name>	Show IPC statistics for an AP with a specific name.
bssid <bssid>	Show IPC statistics for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show IPC statistics for an AP with a specific IP address. Enter the IP address in dotted-decimal format.

Example

The following example shows IPC statistics for the station management process on an AP named **corp-AP-115**.

```
(host-md) #show ipc statistics app-ap ap-stm ap-name corp-AP-115
IP: 168778491, IP_STR: 10.15.90.251

Description

This command displays the IPv4 user table entries. You can filter the output based on various parameters described in the following table. This command should be executed from the managed device only where the APs and client terminate.

Parameter	Description
ap-group <ap-group>	Filter the output of this command by showing users connected to APs that belong to the specified AP group.
ap-name <ap-name>	Filter the output of this command by showing users connected to an AP with the specified AP name.
authentication-method	Filter the output of this command by the authentication method used for the device:
dot1x	Filter the output of this command by showing data for devices using the 802.1X authentication.
mac	Filter the output of this command by showing data for devices using the MAC authentication.
opensystem	Filter the output of this command by showing data for devices using the open (no) authentication.
psk	Filter the output of this command by showing data for devices that do not use authentication but use a PSK for encryption.
stateful-dot1x	Filter the output of this command by showing data for devices using stateful 802.1X authentication.
via-vpn	Filter the output of this command by showing data for devices that authenticate using VIA.
vpn	Filter the output of this command by showing data for devices using VPN authentication.
web	Filter the output of this command by showing data for devices using the Captive Portal authentication.
bssid	Filter the output of this command by showing users connected to the specified BSSID.
debug	Filter the output of this command by showing entries in the IPv4 user-table that are in debug mode.
ssid	Filter the output of this command by showing entries in the IPv4 user table that are associated to the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.
internal	Filter the output of this command by showing internal IPv4 users.
ip <A.B.C.D>	Filter the output of this command by showing IPv4 users that match the specified IPv4 address.
log	Filter the output of this command by showing the log information for the specified IPv4 client.

Parameter	Description
mac	Filter the output of this command by showing users with the specified MAC address.
mobile	Filter the output of this command by showing a list of mobile users in the IPv4 user table. The following filters are available for this parameter: <ul style="list-style-type: none"> ▪ bindings—List of users that have moved away from the current managed device. ▪ rows—Displays entries that match the specified row number. ▪ unique—Displays unique entries in the IPv6 user-table. ▪ visitors—Displays users that have associated with the current managed device.
name	Filter the output of this command by showing IPv4 user table entries that match the specified name.
phy-type	Filter the output of this command by showing IPv4 user table entries that match a or b phy-type.
role	Filter the output of this command by showing IPv4 user table entries that match the specified role.
rows	Filter the output of this command by showing specific rows in the IPv4 user table. Enter the starting row number and the number of rows to be displayed.
station	Filter the output of this command by showing the station table information for the IPv4 user table entries.
verbose	Filter the output of this command by showing the complete IPv4 user table with all details.

Example

The following example displays a list of internal IPv4 user entries:

```
(host-md) #show ipv4 user-table

```

The output of this command includes the following parameters:

Output	Description
IP	IP address of the client in that row that authenticating using 802.1X authentication.
MAC	MAC address of the client.
Name	Name of the client.
Role	The role assigned to the client.
Age (d:h:m)	Total time that client is connected to managed device.
Auth	Authentication type of the client.
VPN link	Clients using VPN authentication.
AP name	Name of the AP associated with the client.
Roaming	Current roaming status of the client.
Essid/Bssid/Phy	ESSID, BSSID, and Phy to which the client is associated.
Profile	The AAA profile to which the client is associated.
Forward Mode	The client traffic forwarding mode.

Related Commands

Command	Description
show user-table	Displays detailed information about the controller's connection to a user device, in regards to mobility state and statistics, authentication statistics, VLAN assignment method, AP datapath tunnel info, radius accounting statistics, user name, user-role derivation method, datapath session flow entries, and 802.11 association state and statistics.

show ipv6 dhcp

```
show ipv6 dhcp
  binding
  database {pool <pool_name>}
  helper <id>
  relay <counters>
  relay-option
  vlan <id>
```

Description

This command displays the DHCPv6 server settings.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
binding	Show DHCPv6 server bindings.
database [pool<pool_name>]	Show DHCPv6 server settings.
helper <id>	Show DHCPv6 helper information.
relay <counters>	Show DHCPv6 relay information.
relay-option	Show DHCPv6 relay option configurations.
vlan <id>	Show DHCPv6 VLAN information. <1-4094> VLAN ID

Examples

The following example shows the DHCPv6 database:

```
(host) [mynode] #show ipv6 dhcp database
DHCPv6 enabled
# 2001-feed-64-nw
subnet6 2001:feed::/120 {
    option vendor-class-identifier "ArubaAP";
    option dhcp6.vendor-opts "2001:feed::235";
    range6 2001:feed::1 2001:feed::234;
    range6 2001:feed::236 2001:feed::ffff:ffff:ffff:fffe;
}
# 2003-feed-64-nw
subnet6 2003:feed::/120 {
```

```

    option vendor-class-identifier "ArubaAP";
    option dhcp6.vendor-opts "2001:feed::235";
    range6 2003:feed::1 2003:feed::234;
    range6 2003:feed::236 2003:feed::ffff:ffff:ffff:fffe;
}
# DHCPv6
subnet6 2001:470:faca:4::/120 {
    default-lease-time 43200;
    max-lease-time 43200;
    option dhcp6.domain-search "test.org";
    option vendor-class-identifier "ArubaAP";
    option dhcp6.vendor-opts "2001:feed::235";
    option dhcp6.name-servers 2001:470:20::2;
    option dhcp6.preference 25;
    option dhcp6.usr-opt-24-DHCPv6 "Domain Search List";
    range6 2001:470:20::1 2001:470:faca:4::1;
    range6 2001:470:20::3 2001:470:faca:4:ffff:ffff:ffff:fffe;
}

```

The following example shows the DHCPv6 database for a specific pool:

```

(host) [mynode] #show ipv6 dhcp database [pool <pool-name>]
(host) [mynode] #show ipv6 dhcp database pool DHCPv6

# DHCPv6
subnet6 2001:470:faca:4::/120 {
    default-lease-time 43200;
    max-lease-time 43200;
    option dhcp6.domain-search "test.org";
    option vendor-class-identifier "ArubaAP";
    option dhcp6.vendor-opts "2001:feed::235";
    option dhcp6.name-servers 2001:470:20::2;
    option dhcp6.preference 25;
    option dhcp6.usr-opt-24-DHCPv6 "Domain Search List";
    range6 2001:470:20::1 2001:470:faca:4::1;
    range6 2001:470:20::3 2001:470:faca:4:ffff:ffff:ffff:fffe;
}

```

The following example shows the DHCPv6 binding information:

```

(host) [mynode] # show ipv6 dhcp binding
# Client: fe80::1cf:2e1:cd13:356b; IA ID 0x13001f3c
ia-na "\023\000\037<\000\001\000\001\030\223\211\242\000%\263J\372\364" {
    cltt epoch 1364206514; # Mon Mar 25 15:45:14 2013
    iaaddr 2001:470:faca:4:21a:1eff:fe00:9e6 {
        binding state expired;
        preferred-life 187;
        max-life 300;
        ends epoch 1364206814; # Mon Mar 25 15:50:14 2013
    }
}

```

The following example shows the DHCPv6 active pools:

```
(host) [mynode] #show ipv6 dhcp active-pools
DHCPv6 Active Pools
-----
Vlan Pool Name
-----
10   DHCPv6
```

The following example shows the DHCPv6 VLAN information:

```
(host) [mynode] (config) #show ipv6 dhcp vlan 1

DHCPv6 Vlan 1 Table
-----
VLAN  PREFIX                HELPER ADDRESS    RELAY OPTION
----  -
1     2002::1, 2004::2         2444::2, 2333::2 L3-Enabled
```

The following example shows the DHCPv6 helper information:

```
(host) #show ipv6 dhcp helper
DHCPv6 User Table
-----
VLAN  HELPER ADDRESS  SOURCE ADDRESS
----  -
3     2444::2         2002::1
3     2333::2         2004::2
```

The following example shows the DHCPv6 relay-option information:

```
(host) #show ipv6 dhcp relay-option
DHCPv6 relay option XML File: test.xml
Circuit-Id:<Client MAC in lower-case with ':' as delimiter>
Remote-Id:<Client MAC in lower-case with ':' as delimiter>
```

Related Commands

Command	Description
ipv6 dhcp pool	This command configures a DHCPv6 pool on the managed device.

Command History

Release	Modification
ArubaOS 8.8.0.0	The following parameters were introduced: <ul style="list-style-type: none"> ■ helper <id> ■ relay <counters> ■ relay-option ■ vlan <id>
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ipv6 dhcp-client

show ipv6 dhcp-client

Description

Shows DHCPv6 client lease information.

Examples

The example below shows the DHCPv6 database:

```
(host) [mynode] #show ipv6 dhcp-client
DHCPv6 enabled
# 2001-feed-64-nw
subnet6 2001:feed::/120 {
    option vendor-class-identifier "ArubaAP";
    option dhcp6.vendor-opts "2001:feed::235";
    range6 2001:feed::1 2001:feed::234;
    range6 2001:feed::236 2001:feed::ffff:ffff:ffff:fffe;
}
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ipv6 firewall

```
show ipv6 firewall
```

Example

This example displays the status of all firewall configurations.

```
(host) [mynode] #show ipv6 firewall
Global IPv6 firewall policies
-----
Policy                               Action   Rate   Port
-----
Monitor TCP SYN attack                Disabled
Monitor IPv6 sessions attack          Disabled
Deny inter user bridging              Disabled
Drop all IPv6 fragments                Disabled
Per-packet logging                    Disabled
Enforce TCP handshake before allowing data Disabled
Prohibit RST replay attack             Disabled
Session Idle Timeout                  Disabled
Prohibit IPv6 Spoofing                 Disabled
Extension header parse length          Disabled
Stateful ICMP Processing                Disabled
Enforce TCP Sequence numbers           Disabled
```

The output of this command includes the following parameters:

Output	Description
Monitor TCP SYN attack	If enabled, the managed device monitors the number of TCP SYN messages per second. If this value exceeds the maximum configured rate, the managed device will register a DoS attack.
Monitor IPv6 sessions attack	If enabled, the managed device monitors the number of TCP session requests per second. If this value exceeds the maximum configured rate, the managed device will register a DoS attack sessions.
Deny inter user bridging	If enabled this setting prevents the forwarding of Layer-2 traffic between wired or wireless users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic.

Output	Description
Drop all IPv6 fragments	If enabled, all IPv6 fragments are dropped.
Per-packet logging	If active, and logging is enabled for the corresponding session rule, this feature logs every packet.
Enforce TCP handshake before allowing data	If enabled, this feature prevents data from passing between two clients until the three-way TCP handshake has been performed. Enabling this option causes mobility to fail. So, disable this option if you have mobile clients on the network as.
Prohibit RST replay attack	If enabled, this setting closes a TCP connection in both directions if a TCP RST is received from either direction.
Session Idle Timeout	Shows if a session idle timeout interval has been defined.
Prohibit IPv6 Spoofing	Status on IPv6 spoofing. When this option is enabled, IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.
Extension header parse length	Shows the extension header parse length, with a maximum value of 100 bytes.
Stateful ICMP Processing	If enabled, stateful ICMP processing is enabled.
Enforce TCP Sequence numbers	
Enable session-spread

show ipv6 interface

show ipv6 interface [brief]

Description

View ipv6 related information on all interfaces.

Parameter	Description
brief	Optional parameter. If specified, displays the ipv6-related information on all the interfaces in a summary format.

Example

```
(host) [mynode] #show ipv6 interface
VLAN1 is up line protocol is down
IPv6 Router Advertisements are disabled
IPv6 is disabled
VLAN46 is up line protocol is up
IPv6 is enabled, link-local address is fe80::1a:1e00:2e00:9f0
Global unicast address(es):
2046:eab::25, subnet is 2046:eab::/64
IPv6 Router Advertisements are disabled
VLAN50 is up line protocol is up
IPv6 Router Advertisements are disabled
IPv6 is disabled
VLAN10 is up line protocol is up
IPv6 is enabled, link-local address is fe80::1a:1e00:a00:9f0
Global unicast address(es):
2010:eab::1, subnet is 2010:eab::/64
fc01:eab::1, subnet is fc01:eab::/64
IPv6 Router Advertisements are enabled
loopback is up line protocol is up
IPv6 is enabled, link-local address is fe80::1a:1e0f:ff00:9f0
Global unicast address:
2046:eab::2, subnet is 2046:eab::2/128
TUNNEL2 is up line protocol is up
tunnel mode is Layer2 IPv6 GRE, tunnel vlan 10
tunnel source ipv6 address is 2046:eab::25
tunnel destination ipv6 address is 2047:eab::25

(host) [mynode] #show ipv6 interface brief
Interface                [Status/Protocol]

show ipv6 mld

```
show ipv6 mld
  cluster
  config
  counters
  group
  interface
  proxy-group
  proxy-mobility-group
  proxy-mobility-stats
  proxy-stats
```

Description

Shows MLD information.

Parameter	Description
cluster	Shows cluster information.
config	Shows MLD configuration.
counters	Shows MLD counters.
group	Shows MLD group information.
interface	Shows MLD interface information.
proxy-group	Shows interface specific MLD proxy group information.
proxy mobility group	Shows interface specific MLD proxy mobility group information.
proxy-mobility-stats	Shows MLD proxy mobility specific statistics.
proxy-stats	Shows MLD proxy specific statistics.

Command History

Release	Modification

show ipv6 mld cluster

```
show ipv6 mld cluster
  aac-info
  bss-info
  client-info
  dmo-off-info
  info
  proxy-group
  stats
```

Description

Display MLD configuration details for a cluster.

Parameter	Description
aac-info	Show cluster AAC information of APs.
bss-info	Show IGMP BSS information.
client-info	Show IGMP cluster client information.
dmo-off-info	Show list of (S,G,BSS) where DMO threshold is hit.
info	Show cluster information.
proxy-group	Show IGMP cluster proxy database group information.
stats	Show cluster statistics.

Example

The following example displays output of the `show ipv6 mld cluster` command.

```
(host)[node] # show ipv6 mld cluster
Cluster information

Clustering      Enabled
Version        IPv6
Redundancy     Enabled

TABLE
-----
Controller IP      Connected State  Multicast Vlan  Priority
-----
Self              Yes              0                128

```

Related Commands

Command	Description
ipv6 mld	This command configures the IPv6 MLD (Multi-listener discovery) parameters.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Config or Enable mode on managed device.

show ipv6 mld config

```
show ipv6 mld config
```

Description

Displays MLD configuration details.

Example

This example displays the current MLD configuration values.

```
(host) [mynode] #show ipv6 mld config
MLD Config
-----
Name                Value
-----
robustness-variable 2
query-interval      125
query-response-interval 100
max-members-per-group 300
ssm-range           FF3X::4000:1 - FF3X::FFFF:FFFF
```

The output of this command includes the following parameters:

Output	Description
robustness-variable	Denotes the value that is used to calculate the timeout value of an MLD client.
query-interval	Denotes the time interval at which the MLD query is sent.
query-response-interval	Denotes the time interval at which the MLD query response should be received.
max-members-per-group	Denotes the maximum members per group.
ssm-range	Denotes the source specific multicast range. When you enter the SSM Range ensure that the upstream router has the same range, else the multicast stream would be dropped. NOTE: Only SSM enabled clients can subscribe to the multicast stream in the multicast range. The default ssm-range in case of IPv6 is FF3X::4000:1 - FF3X::FFFF:FFFF, this range is configurable. If MLDv1 or a non SSM client sends a report on a specified SSM range, it is rejected by the managed device.

show ipv6 mld counters

show ipv6 mld counters

Description

Displays the statistics of MLD.

Example

This example displays the MLD statistics for the following values.

```
(host) [mynode] #show ipv6 mld counters
MLD Statistics
-----
Name                Value
----                -
received-total      0
received-queries    0
received-v1-reports 0
received-v1-leaves  0
received-v2-reports 0
received-unknown-types 0
len-errors           0
checksum-errors     0
not-vlan-dr         0
transmitted-queries 0
forwarded            0
non-conforming-mld  0
```

The output of this command includes the following parameters:

Output	Description
received-total	The total number of MLD messages.
received-queries	The total number of MLD queries.
received-v1-reports	The total number of MLD v1 reports received.
received-v1-leaves	The total number of MLD v1 leave messages received.
received-v2-reports	The total number of MLD v2 reports received.
received-unknown-types	The total number of unrecognized messages received.
len-errors	The total number of error message where the length check has failed.

Output	Description
checksum-errors	The total number of error message where the checksum has failed.
not-vlan-dr	The number of messages received for which the current managed device is not the designated router.
transmitted-queries	The total number of transmitted MLD queries.
forwarded	The total number of MLD messages forwarded.
non-conforming-mlد	The total number of non confirming MLD messages.

show ipv6 mld group

show ipv6 mld group

Example

This example displays MLD group details.

```
(host) [mynode] #show ipv6 mld group
MLD Group Table
-----
Group                Members  Mode    Age
-----
ff02::1:ff00:0       2        Exclude  4
ff02::1:ff00:1900    2        Exclude  1
ff1e::2              2        Include  0
ff02::1:3            4        Exclude  1
ff02::202            2        Exclude  4
ff02::2              3        Exclude  1
ff02::1:ff20:d6e2    2        Exclude  4
ff02::c              4        Exclude  2
ff02::1:ffab:4027    2        Exclude  6
ff02::d              2        Exclude  1
ff02::1:ff00:12      2        Exclude  4
ff02::1:ffd6:4d41    1        Exclude  7
ff02::16             2        Exclude  1
ff02::1:ffd6:4d40    1        Exclude  1
ff02::1:ff8a:4951    2        Exclude  4
ff02::1:ff5b:aac4    2        Exclude  11
ff02::1:ff9f:df01    2        Exclude  3
Total Groups: 17
```

The output of this command includes the following parameters:

Output	Description
Group	Name of MLD groups.
Members	Number of members in an MLD group.
Mode	Managed device supports two IPv6 multicast source filtering modes - Include and Exclude. In Include mode, the reception of packets sent to a specified multicast address is enabled only from the source addresses listed in the source list. In Exclude mode, the reception of packets sent to a specific multicast address is enabled from all source addresses (MLDv1 mode).
Age	This parameter specifies the aging time.

This example displays MLD group address details.

```
(host) [mynode] #show ipv6 mld group maddr ff1e::2 mac 9c:b7:0d:3f:a8:fc
MLD member 9c:b7:0d:3f:a8:fc Table
-----
Source          Age
-----
2001:feed::2   26
```

The output of the `show ipv6 mld group` command includes the following parameters:

Parameter	Description
Source	IP address of the multicast source.
Age	This parameter specifies the aging time.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ipv6 mld interface

```
show ipv6 mld interface
```

Example

This example displays MLD status on VLANs. To view details for a specific VLAN, you can specify the VLAN ID.

```
(host) [mynode] #show ipv6 mld interface
MLD Interface Table
-----
VLAN  Link local address  Snooping  Proxy    Querier  Querier-dest
Upstream querier  Upstream port
-----
-----
1      ::                    disabled  disabled  ::       unknown   ::
      -
160    ::                    disabled  disabled  ::       unknown   ::
      -
```

The output of this command includes the following parameters:

Parameter	Description
VLAN	Denotes the VLAN ID.
Link local address	IP address of the VLAN interface.
Snooping	Status of MLD snooping.
Proxy	Status of MLD proxy configuration.
Querier	IPv6 address of the MLD querier for the VLAN.
Querier-dest	Denotes the destination of MLD querier on VLAN.
Upstream querier	Denotes the address of upstream MLD querier on VLAN.
Upstream port	Denotes the destination of upstream MLD querier on VLAN.

show ipv6 neighbors

```
show ipv6 neighbors
  counters
  vlan
```

Description

Displays the IPv6 neighbors configured on a VLAN interface. This command displays the IPv6 neighbors configured on a VLAN interface via the [ipv6 neighbor](#) command.

Description

Shows IPv6 commands.

Parameter	Description
counters	Shows neighbor cache counters.
vlan	Shows the vlan Ids.

Examples

The example below shows the ipv6 neighbors configured on VLAN 1 .

```
(host) [mynode] #show ipv6 neighbors vlan 1
IPv6 Neighbors
-----
IPv6 Address          Age   Link-layer Addr      State      Interface
-----
2cce:205:160:100::fe  -    00:0b:86:61:13:28    PERMANENT  vlan 1

show ipv6 netlink

```
show ipv6 netlink
  stats
```

Description

This command displays the netlink information.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
stats	Displays netlink statistics.

Examples

The following example shows the netlink statistics:

```
(host) [mynode] #show ipv6 netlink stats

IPv6 address add total           : 3
IPv6 address add DAD fail       : 0
IPv6 address delete total      : 2
IPv6 link up total              : 0
IPv6 link down total            : 0
IPv6 add route total            : 13
IPv6 add route destination      : 12
IPv6 add route source           : 0
IPv6 add route gateway          : 0
IPv6 add route unspecified      : 0
IPv6 add route other            : 1
IPv6 delete route total         : 7
```

```
IPv6 delete route destination : 7
IPv6 delete route source      : 0
IPv6 delete route gateway     : 0
IPv6 delete route unspecified : 0
IPv6 delete route other       : 0
Unspecified event             : 0
```

show ipv6 nexthop-list

```
show ipv6 nexthop-list
  details STRING
  STRING
```

Description

This command displays the next hop list settings for policy-based routing in IPv6 address. A next hop IP is the IPv4 or IPv6 address of an adjacent router or device with layer-2 connectivity to the managed device. The next hop list provides redundancy for the next hop devices by forwarding the traffic to a backup next hop device in case of failures. If the active next hop device on the list becomes unreachable, traffic matching a policy-based routing ACL is forwarded using the highest-priority active next hop on the list. For more information on this feature, see [ip nexthop-list on page 871](#).

The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
details	Displays detailed next-hop settings for policy-based routing.
STRING	Displays the next-hop settings based on the next-hop list name.

Example

The following command displays the configuration settings for the one configured next hop list.

```
(host) [mynode] #show ipv6 nexthop-list
IPv6 Nexthop-List Entries
-----
Name      Dest  Preemptive Failover  Nexthop          Nexthop Dest
Nexthop  Priority
-----  -
-----
test      0x4402      Enabled      2032:1202:4072::2111  0x4421
1
test2    0x4403      Enabled      2006::3           0x4422
128
```

The output of this command displays the following information

Parameter	Description
Name	Name of the next hop list.
Dest	Destination prefix address.
Preemptive Failover	This column indicates whether preemptive failover is enabled or disabled. If preemption is enabled and a higher priority next hop becomes reachable again, packets are again forwarded to the higher priority next hop.
Nexthop	Next hop IPv6 address.
Nexthop Dest	Next hop destination prefix address.
Nexthop Priority	List of the IPv6 addresses of all next hop IPs, including the priority assigned to each device when the list was configured.

show ipv6 pd

```
show ipv6 pd
status
```

Description

Displays the prefix obtained by the PD client on uplink.

Example

The following example displays the status of the IPv6 prefix delegation.

```
(host)[mynode] #show ipv6 pd status
DHCPv6 PD Client is enabled
Uplink VLAN      : 100
Label           : site1
Prefix          : 2001:0:3::/48
65536 unique /64 prefixes are derivable from the acquired IA PD lease
Preferred lifetime 604800s, Valid lifetime 2592000s
Last request/renewal for the lease done at Thu Apr 14 04:46:15 2016
Lease expires at Sat May 14 04:46:15 2016
Downlink VLANs
-----
VlanId  Prefix
-----  -----

show ipv6 ra

```
show ipv6 ra
  proxy
  status
```

Description

Displays the RA proxy server information and IPv6 RA.

Parameter	Description
proxy	Shows RA proxy server information.
status	Shows the status of IPv6 Router Advertisements.

Examples

The example below shows the IPv6 RA status on the VLAN interfaces .

```
(host) [mynode] #show ipv6 ra status
IPv6 RA Status
-----
VlanId  State    Prefix(es)
-----  -
1        enabled  2001:abcd:1234:dead::/64
220     enabled  2200:eab:feed:12::/64
230     enabled  2300:eab:feed::/64
7        enabled  2001:470:faca:2::/64
                2001:470:faca:3::/64
                2001:470:faca:4::/64

The example below shows the status of the IPv6 proxy RA:
(host) #show ipv6 ra proxy
IPv6 RA Proxy status: enabled
IPv6 RA Proxy interval: 600
```

show ipv6 route

```
show ipv6 route
  counters
  static
```

Description

Displays the IPv6 routing table. This command displays static IPv6 routes configured on the managed device via the [ipv6 route](#) command. Use the [ipv6 default-gateway](#) command to set the default gateway to the IPv6 address of the interface on the upstream router or switch to which you connect the managed device.

Command	Description
counters	Displays the number of routes present, categorized by type.
static	Include this optional parameter to display only static IPv6 routes.

Examples

The examples below show the ipv6 address of routers and the VLANs to which they are connected.

```
(host) [mynode] #show ipv6 route
Codes: C - connected, O - OSPF, R - RIP, S - static
       M - mgmt, U - route usable, * - candidate default

Gateway of last resort is 2001::3 to network ::/128 at cost 1
S*   ::/0 [1/0] via 2001::3*
C    2001::/64 is directly connected, VLAN1
C    2010:abcd:1234:dead::/64 is directly connected, VLAN10

(host) [mynode] #show ipv6 route static
Gateway of last resort is 2001::3 to network ::/128 at cost 1
S*   ::/0 [1/0] via 2001::3*
```

show ipv6 user-table

```
show ipv6 user-table
  ap-group <ap-group>
  ap-name <ap-name>
  authentication-method <dot1x|mac|opensystem|psk|stateful-dot1x|via-vpn|vpn|web>
  bssid <A:B:C:D:E:F>
  debug
  essid <STRING>
  internal
  ip <A.B.C.D> [log]
  mac <A:B:C:D:E:F>
  mobile {[bindings][visitors]}
  name <STRING>
  phy-type {[a]|[b]}
  role <STRING>
  rows <NUMBER> <NUMBER>
  station <rows|unique>
  verbose <rows|unique>
```

Description

Displays IPv6 user table entries. You can filter the output based on various parameters are described in table.

Parameter	Description
ap-group <ap-group>	Filter the output of this command by showing users connected to APs that belong to the specified AP group.
ap-name <ap-name>	Filter the output of this command by showing users connected to an AP with the specified AP name.
authentication-method	Filter the output of this command by the authentication method used for the device:
dot1x	Show data for devices using 802.1X authentication.
mac	Show data for devices using MAC authentication.
opensystem	Show data for devices using open (no) authentication.
psk	Show data for devices that do not use authentication but use a PSK for encryption.
stateful-dot1x	Show data for devices using stateful 802.1X authentication.
via-vpn	Show data for devices that authenticate using Aruba VIA.
vpn	Show data for devices using VPN authentication.

Parameter	Description
web	Show data for devices using captive portal authentication.
bssid	Displays entries in the IPv6 user-table that are associated to the specified BSSID.
debug	Displays entries in the IPv6 user-table that are in debug mode.
ssid	Displays entries in the IPv6 user-table that are associated to the specified ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.
internal	Displays internal IPv6 users.
ip <A.B.C.D>	Displays IPv6 users that match the specified IPv6 IP address.
log	Displays the log information for the specified IPv6 client.
mac	Displays users with the specified MAC address.
mobile	Displays list of mobile users in the IPv6 user table. The following filters are available for this parameter: <ul style="list-style-type: none"> ▪ bindings—list of users that have moved away from the current controller. ▪ rows—displays entries that match the specified row number. ▪ unique—displays unique entries in the IPv6 user-table. ▪ visitors—displays users that have associated with the current controller.
name	Displays IPv6 user table entries that match the specified name.
phy-type	Displays IPv6 user table entries that match a or b phy-type.
role	Displays IPv6 user table entries that match the specified role.
rows	Displays specific rows in the IPv6 user table. Enter the starting row number and the number of rows to be displayed.
station	Displays the station table information for the IPv6 user table entries.
verbose <rows unique>	Displays the complete IPv6 user table with all details.

Example

This example displays a list of users.

```
(host) [mynode] #show ipv6 user-table
Users
-----
IP                               MAC                               Name   Role   Age
(d:h:m)  Auth   VPN link  AP name  Roaming  Essid/Bssid/Phy
          Profile Forward mode  Type    Host Name
-----
-----

2003:d81f:f9f0:1001:617c:9151:6d25:f754  00:16:ce:2c:b4:85  Wing-A  logon
00:00:06  802.1X          00:0b:86:c1:0e:8c  Wireless Wing-
A/00:0b:86:90:e8:c0/g  default-dot1x
```

The output of this command includes the following parameters:

Parameter	Description
IP	IP address of the client in that row that authenticating using 802.1X
MAC	MAC address of the client.
Name	Name of the client.
Role	The role assigned to the client.
Age (d:h:m)	Total time that client is connected to controller.
Auth	Authentication type.
AP name	Name of the AP associated with the client.

Parameter	Description
Roaming	Current roaming status of the client.
Essid/Bssid/Phy	ESSID or BSSID or Phy to which the client is associated.
Profile	Displays the AAA profile.

Command History

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show jitter

```
show jitter <probe_ip> <src_intf>
```

Description

This command displays the debug messages for the IPsec tunnel manager. This command should be executed from the managed device only.

Parameter	Description
<probe_ip>	IP address of a remote host to which the managed device is connected.
<src_intf>	Source interface VLAN of a remote host to which the managed device is connected.

Related Commands

Command	Description
ip probe health-check	This command configures WAN health-check ping-probes for measuring WAN availability and latency on managed device up-links.

show keys

```
show keys [all]
```

Description

This command displays if optional keys and features are enabled or disabled on Mobility Conductor.

Parameter	Description
all	Include this optional parameter to display the status of all optional keys and features. If this parameter is omitted, the output displays the status of the most commonly used features and keys.

Example

The following example displays the status of the most commonly used keys and features on Mobility Conductor:

```
(host) [mynode] #show keys all
Licensed Features
-----

show lacp

```
show lacp
  summary
  sys-id
  <id> {counters|internal|neighbor}
```

Description

This command displays the Link Aggregation Control Protocol (LACP) configuration status.

Parameter	Description
summary	Displays summary of all LACP information and statistics.
sys-id	Displays LACP system ID.
<id>	Specify group ID. Range is 0-7.
counters	Enter the keyword counters to view the LACP traffic.
internal	Enter the keyword internal to view the LACP internal information.
neighbor	Enter the keyword neighbor to view the LACP neighbor information.

Example

This command returns the port priority and the MAC address (comma separated). In the example below, the port priority is the default value 32768 followed by the MAC address 00:0B:86:40:37:C0.

```
(host) [mynode] #show lacp sys-id
32768,00:0B:86:40:37:C0
```

The port uses the group number +1 as its “actor admin key”. By default, all the ports use the long timeout value (90 seconds).

```
(host) [mynode] #show lacp 0 neighbor
Flags:  S - Device is requesting Slow LACPDUs
        F - Device is requesting fast LACPDUs
        A - Device is in active mode P - Device is in passive mode
Partner's information
-----
Port    Flags  Pri  OperKey  State Num  Dev Id
-----
```

```
FE 1/1 SA 1 0x10 0x45 0x5 00:0b:86:51:1e:70
FE 1/2 SA 1 0x10 0x45 0x6 00:0b:86:51:1e:70
```

When a port, in a LAG, is disconnected (that is, the partner device is different than the other ports or the neighbor times out or can not exchange LACPDUs with the partner), the port status is displayed as **DOWN**. See the following example.

```
(host) [mynode] #show lacp 0 internal
Flags: S - Device is requesting Slow LACPDUs
       F - Device is requesting fast LACPDUs
       A - Device is in active mode P - Device is in passive mode
Port   Flags  Pri  AdminKey  OperKey  State Num  Status
-----
FE 1/1 SA    1    0x1       0x1      0x45  0x2  DOWN
FE 1/2 SA    1    0x1       0x1      0x45  0x3  UP
```

The “counters” option allows you to view LACP received (Rx) traffic, transmitting (Tx) traffic, data units (DU) received and transmitted by port.

```
(host) [mynode] #show lacp 0 counters
Port   LACPDUtx  LACPDURx  MarkrTx  MarkrRx  MrkrRspTx  MrkrRspRx
-----
FE 1/1  10         10         0         0         0           0
FE 1/2  12         12         0         0         0           0
```

show lc-cluster

```
show lc-cluster
  bucket [distribution {all|ssid <ssid-name>}]
  bucketmap [publish {counters}]
  exclude-vlan
  global-events
  group-membership
  group-profile
  gsm counters
  heartbeat counters
  history
  load distribution
  papi counters
  upgrade
  scheduled-upgrades
  vlan-probe
  <profile> {ap|controller|upgrade}
```

Description

Displays information related to vlan, membership, profile, heartbeat, and so on for a cluster. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
bucket distribution all	Displays the current bucket distribution for all the ESSIDs.
bucket distribution ssid <ssid-name>	Displays the current bucket distribution for a specific ESSID.
bucketmap publish counters	Displays the details of the published bucketmap counters.
exclude-vlan	Displays a list containing vlans excluded from L2 Probing.
global-events	Displays cluster events.
group-membership	Displays the active cluster member of cluster profile
group-profile	Displays the cluster profile
gsm counters	Displays the counters pertaining to various GSM events
heartbeat counters	Displays the peer disconnection events statistics.
history	Displays cluster history.
load distribution	Displays the current load distribution

Parameter	Description
ap	Displays the current load distribution on the AP
client	Displays the current load distribution on the client
papi	Displays the cluster messaging related counters.
vlan-probe	Displays the Cluster VLAN Probe information.
<profile>	Displays the name of the cluster profile.
ap {details}	Displays the details of the APs in the cluster.
controller {details ip ipv6}	Displays the controllers details in the cluster. Use one of the following parameters: <ul style="list-style-type: none"> ▪ details—Displays the details of the controllers in the cluster. ▪ ip <ipv4_addr> [active {ap [details]}]—Displays the IP address details of the controllers in the cluster. ▪ ipv6 <ipv6_addr> [active {ap [details]}]—Displays the IPv6 address details of the controllers in the cluster.
upgrade	Displays the upgrade details of controllers and APs in the cluster. Use one of the following parameters: <ul style="list-style-type: none"> ▪ stats: Displays the statistics of the cluster upgrade. ▪ status: Displays the upgrade status of each controller and AP.
rap-public-ip	Displays the public IP address of the Remote AP cluster configured behind NAT.
scheduled-upgrades	Displays the status of all the clusters scheduled for an upgrade.

Example

An example output of the `show lc-cluster group-membership` command for a cluster running ArubaOS 8.11.0.0 or later versions.

```
Cluster Enabled, Profile Name = "test4nodecluster"

Related Commands

Command	Description
lc-cluster group-profile	This command is used to configure the cluster group profile in the Mobility Conductor.
lc-cluster group-membership	This command configures the group-membership in each node. This command is used to enable the cluster membership on the managed devices.
show datapath cluster details	This show command displays heartbeat threshold values, datapath assignments, number of peers and peer data statistics.
show datapath cluster heartbeat counters	This command displays information related to cluster heartbeat counters.
show lc-cluster history	This command displays the history of the connection and disconnection events with a reason and the time stamp.

Command History

Release	Modification
ArubaOS 8.11.0.0	The following changes were introduced: <ul style="list-style-type: none"> ■ The <code>active-client-rebalance-threshold</code>, <code>standby-client-rebalance-threshold</code>, and <code>unbalance-threshold</code> fields were removed from the output of the <code>show lc-cluster group-membership</code> command. ■ The <code>bucket distribution all</code>, <code>bucket distribution essid <ssid-name></code>, and <code>bucketmap publish counters</code> parameters were added.
ArubaOS 8.7.0.0	The functionality of <code>heartbeat counters</code> parameter was modified.

Release	Modification
ArubaOS 8.5.0.0	The load balance thresholds were updated in the output and the Starting VRRP ID and VRRP Passphrase fields are added in the output.
ArubaOS 8.4.0.0	The parameter <code>scheduled-upgrades</code> and <code>rap-public-ip</code> were added.
ArubaOS 8.2.0.0	The parameter details of <code><profile></code> were added.
ArubaOS 8.0.0.0	Command introduced.

show lc-rap-pool

show lc-rap-pool <pool_name>

Description

This command displays the remote AP inner IP pool for cluster deployment.

Parameter	Description
pool_name	Name of the local IP pool to show.

Example

The output of the example below displays the Remote AP inner IPv4 and IPv6 pool that can be used for cluster deployment.

```
(host) [mynode] (config) #show lc-rap-pool rap-cluster
IP addresses used in pool rap-cluster
200.1.1.1-200.1.1.11
200.1.1.13
IPv6 addresses used in pool v6pool
fd00::1-fd00::b
fd00::d
IPv4 pool : Total - 12 IPs used - 88 IPs free - 100 IPs configured
IPv6 pool : Total - 12 IPs used - 243 IPs free - 255 IPs configured
LC RAP Pool Total Allocs/Deallocs/Reserves : 4/2/0
LC RAP Pool Allocs/Deallocs/Reserves(succ/fail) : 4/2/(22/0)
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show license

```
show license
  aggregate
  asp
  box
  capacity-details
  client-table
  debug
  heartbeat
  key
  keys
  limits
  md-pefv-lic
  passphrase
  platform-limits
  pool-profile
  remote
  server-table
  summary
  verbose
```

Description

Displays the license table or Mobility Conductor passphrase.

Parameter	Description
<u>aggregate</u>	Displays the license aggregate table.
<u>asp</u>	Displays the Aruba Support Portal license.
<u>box</u>	Shows box license information.
capacity-details	Displays capacity license details on the device. NOTE: This option is valid only on 9240 controllers.
<u>client-table</u>	Displays license client-table entries
<u>debug</u>	Displays debug information.
<u>heartbeat</u>	Shows the license heartbeats.
<u>key</u>	Shows single license key's information
<u>keys</u>	Shows license keys information based on feature/license type.

Parameter	Description
limits	Enter the keyword limit to display the current license limits.
md-pefv-lic	Displays the MD PEFV license information.
passphrase	Issue the <code>show license passphrase</code> command to identify the Mobility Conductor passphrase. This passphrase is used in the licensing website to generate a Mobility Conductor (MM) license, or to generate a sharable license that can be added to Mobility Conductor license pools.
platform-limits	Displays the current platform license limits.
pool-profile	Shows license pool profile.
remote	Displays the license management remote command.
server-table	Displays License server-table entries
summary	Shows license summary information.
verbose	Displays the verbose output (deprecated, output is always verbose).

Example

An example output of the `show license` command.

```
(host)[node] # show license

```

The output of this command includes the following data columns:

Parameter	Description
Key	The license key.
Installed	The license installation date and time.
Expires	The date that your evaluation license expires is listed in this column. Permanent license will always have a "Never" in this column. Expired evaluation licenses will also be indicated in this column.
Flags	This column displays the status of your license. The legend for this column appears at the bottom of the display output. They are: A: The license is auto-generated. E: The license is fully enabled. R: You must reboot your controller to fully enable this license. M: The license is activated using Master Token Key.
Service Type	The license name (feature).

Related Commands

All platforms	Base operating system.	Config mode on Mobility Conductor.

show license aggregate

```
show license aggregate
pool
```

Description

Display the total number of licenses of each license type in all Mobility Conductor licensing pools. Execute this command from any configuration node in the Mobility Conductor CLI to view the licenses in the global licensing pool and any local license pools, as well as the number of clients using each pool.

Example

The following example displays output of the `show license aggregate` command.

```
(host)[node] # show license aggregate
Aggregate License Table for pool /
-----
Hostname      IP Address  Mac addr  AP   PEF  RF Protect  xSec Module  ACR

```

Parameter	Description
<code>Last update (secs. ago</code>	Time, in seconds, that has elapsed since the licensing table on Mobility Conductor was updated.
<code>Total number of clients</code>	This value indicates the total number of clients using licenses from the licensing pool.

Related Commands

Command	Description
<code>show license key</code>	Display information about a specific license key.
<code>show license keys</code>	Display information about all installed license keys.
<code>show license box</code>	Display the device-specific licenses used by a managed device.

Command History

Release	Modification
ArubaOS 8.6.0.0	The output of the command also displayed the IPv6 address under <code>IP address</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system	Enable and config mode on Mobility Conductor.

show license asp

```
show license asp
  stale
  unallocated-lic
```

Description

Displays Aruba Support Portal information.

Parameter	Description
stale	Displays stale ASP licenses.
unallocated-lic	Displays the Aruba Support Portal unallocated available license count.

Example

The following example displays output of the `show license asp stale` command.

```
(host)[node] # show license asp stale
```

The following example displays output of the `show license asp unallocated-lic` command.

```
(host)[node] # show license asp unallocated-lic
```

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable and config mode on Mobility Conductor.

show license box

```
show license box remote
  remote-ip-addr <ip-addr>
```

Description

Display the device-specific licenses used by a remote managed device. Also, execute this command from the CLI of a managed device to view license limits applied to that managed device from its licensing pool.

Parameter	Description
remote remote-ip-addr <ip-addr>	IP address of the managed device.

Example

The following example displays output of the `show license box remote remote-ip-addr <ip-addr>` command.

```
Box Licenses Table
-----
Key                               Feature
Expiration  Status
---          -
-----

Never          E/Active
V3rBYtzd-hOtVXuKi-WZeEYJU1-9k  Policy Enforcement Firewall for VPN users
Never          E/Active
```

The output of this command includes the following data columns:

Parameter	Description
Key	License key on the managed device.
Feature	Licensing feature enabled by the license key.
Expiration	This field displays the expiration date for evaluation or subscription licenses.
Status	Current status of the license.

Related Commands

Command	Description

```

The output of this command includes the following data columns:

Parameter	Description
Service Type	Type of license on the managed device.
System Limit	The maximum number of licenses supported by the man platform.
Server Lic.	Number of licenses available for use by the licensing client. NOTE: This number is limited by the total license capacity of the managed device platform. A managed device cannot use more licenses than is supported by that managed device platform, even if additional license are available.
Used Lic.	Total number of licenses of each license type used by the managed device.
Remaining Lic.	Total number of remaining licenses available in the licensing pool.
Feature Bit	This column indicates whether these license features are enabled or disabled. For more information about enabling a sharable license, see license-pool-profile-root .

All platforms	Base operating system.	Enable and Config mode on managed devices.

show license debug

```
show license debug
  auth-feature-bits
  feature-bits
```

Description

Displays a summary of Mobility Conductor's/Mobility Conductor's licensing role and IP address.

Parameter	Description
auth-feature-bits	Displays feature bits at auth for this controller.
feature-bits	Displays cached license feature bits for this controller

Example

The following example shows the output of the `show license debug` command.

```
(host)[node] # show license debug
Summary of licensing state
Centralized Licensing: Enabled
Switch Role: Master/ Conductor
License Role: License Client
Master/Conductor IP: 10.9.217.71
Master/Conductor IPv6: 2002::1
Switch IP: 10.16.16.160
Switch IPv6: 2002::2
License Server IP: 10.9.217.71 (or 2002::1 as configured)
```

The output of this command includes the following data columns:

Parameter	Description
Centralized licensing	Shows if centralized licensing is enable or disabled.
Switch Role	Role of the device using the configuration on which this command is run.
License Role	Licensing role of the controller on which this command is run. Mobility Conductor can be a licensing client or a licensing server. Managed devices can be licensing clients only.
Master/Conductor IP	IPv4 address used by Mobility Conductor. If a Mobility Conductor redundant pair is using VRRP, this parameter displays the VRRP virtual IP address.

Parameter	Description
Master/Conductor IPv6	IPv6 address used by Mobility Conductor.
Switch IP	IPv4 address assigned to the device using the configuration on which this command is run.
Switch IPv6	IPv6 address assigned to the device using the configuration on which this command is run.
License Server IP	Mobility Conductor IP address.

The following example shows the output of the `show license debug feature-bits` command.

```
(host)[node] # show license debug feature-bits

show license heartbeat stats

```
show license heartbeat stats
```

Description

Display the license heartbeat statistics between the centralized licensing server and the license client. If your deployment uses the centralized licensing feature, issue this command from the CLI of a centralized licensing server to view heartbeat requests to and responses from each licensing client associated to that licensing server. If you issue this command from a licensing client, the output displays information for that one client only.

Example

The following example displays output of the `show license heartbeat stats` command issued from the licensing server.

```
(host)[node] #show license heartbeat stats
License Client Heartbeat Table
-----
Server IP Address  Mac Addr           HB Req   HB Resp   Total Missed
Last Update (secs. ago)
-----
10.17.52.195      00:0c:29:bb:0f:8f  13843    13836     7
2
License Server Heartbeat Table
-----
Client IP Address  Mac Addr           HB Req   HB Resp   Total Missed
Last Update (secs. ago)
-----
10.17.24.22       00:1a:1e:00:d9:40  13844    13843     1
28
```

The output of this command includes the following data columns for License Heartbeat Table and License Server Heartbeat Table:

Parameter	Description
Server IP address	IPv4 or IPv6 address of the licensing client.
Mac Addr	MAC address of the licensing client.
HB Req	Heartbeat requests sent from the licensing client.
HB Resp	Heartbeat responses received from the license server.

Parameter	Description
Total Missed	Total number of heartbeats that were not received by the licensing client.
Last Update	Number of seconds elapsed since the licensing client last sent a heartbeat request.

Related Commands

Parameter	Description
show license aggregate	View additional statistics for license usage on the licensing server master/ conductor .

Command History

Release	Modification
ArubaOS 8.6.0.0	The command output also displayed IPv6 address information in <code>IP Address</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable mode on centralized licensing master/ conductor or licensing client controllers.

show license key

```
show license key <key>
```

Description

Display information about a specific evaluation or subscription license key. Issue this command from the Mobility Conductor CLI to view the status of an installed evaluation or subscription license key.

Parameter	Description
<key>	License key

Example

The following example displays output for the `show license key` command. In this example, the output has been modified to appear in two separate sections. In the actual CLI, this output appears in a single, long row.

```
(host)[node] #show license key eLNB351-21F-3WE

Key Attributes:
-----
Feature  Type          Expiration          GraceExpiration      TotalCount
-----  -
WebCC    Subscript  2017-05-03 10:36:54  2017-08-31 10:36:54  10

-----  -----
10                      E/Active
Flags: E - enabled; R - reboot/activation key required to activate; D - Not
enabled on Local Controller
```

The output of this command includes the following data columns:

Parameter	Description
Key	License key
Feature	Feature type supported by the license key
Type	ArubaOS supports the permanent , evaluation or subscription license types, but this command displays information about evaluation and subscription licenses only.

Parameter	Description
Expiration	The expiration date for the subscription or evaluation license key.
GraceExpiration	The grace period for which a subscription remains fully active after the subscription key expiration date.
TotalCount	The total number of licenses supported by the license key.
AvailableforAllocation	The total number of licenses that are still available for allocation
Status	This column shows the current status of the license, including whether it is active or expired, and whether that licensing feature is enabled on Mobility Conductor or the stand-alone controller.

Related Commands

Command	Description

show license passphrase

Description

Display the Mobility Conductor passphrase used to generate licenses for a Mobility Conductor deployment. Issue this command for a network where the Mobility Conductor software is installed on a VM.

This command is not supported on stand-alone controllers, the Mobility Conductor appliance or managed devices.

Example

```
(host)[node] #show license passphrase  
5I0N3bI6-exkTWLkq-P05tfofQ-d6NvLJR91
```

Related Commands

Command	Description
show inventory	Display the Mobility Conductor serial number used to generate licenses for a Mobility Conductor deployment.
product serial-number	This command configures the product serial-number for a managed device on a Virtual Machine (VM).

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

show license platform-limits

show license platform-limits

Description

Display the licensing limits for Mobility Conductor or the controller platform upon which this command is issued. To view licensing limits for Mobility Conductor managed devices, you must access the CLI of that specific node.

The output of this command displays limits for currently supported licenses, as well as limits for deprecated license types no longer supported by this software version.

Example

The output of the following command displays platform limits for all licenses supported by Mobility Conductor.

```
(host)[node] #show license platform-limits
License Platform Limits
-----
Limit   Value
-----  -
999999  Access Points
999999  Remote Access Points
999999  Ortronics Access Points
999999  Outdoor Mesh Access Points
999999  Wireless Intrusion Protection Module
999999  VPN Service Module
4096    xSec Users
999999  Indoor Mesh Access Points
999999  120abg Upgrade
999999  121abg Upgrade
999999  124abg Upgrade
999999  125abg Upgrade
999999  Policy Enforcement Firewall Module
999999  Advanced Cryptography
0       SAP
999999  WebCC
999999  Beta AP
```

The following example displays platform limits for all licenses supported by a 7005 controller.

```
(host)[node] #show license platform-limits
License Platform Limits
-----
Limit   Value
```

```

-----
16      Access Points
16      Remote Access Points
16      Ortronics Access Points

show license server-table

show license server-table

Description

Display the license server table for each licensing pool as it appears on the centralized licensing server.

If your deployment uses the centralized licensing feature, issue this command from the CLI of a centralized licensing server to view licensing counts for each supported license type.

Example

The following example displays part of the output of the `show license server-table` command issued from a licensing server. The complete output displays a separate table for each licensing pool.

```
(host) [node] #show license server-table
License Server Table for pool /
-----
Service Type          PoolSize  ExpiredLic  ActualPoolSize  UsedLic
RemainingLic  Warnings  FeatureBit
-----
-----

    None
```

VIA	0	0	0	0	0
None			enabled		

The output of this command includes the following data columns:

Parameter	Description
ServiceType	Type of license on the licensing server.
PoolSize	The total number of licenses assigned to that licensing pool. This number includes both expired and active licenses.
ExpiredLic	Number of expired licenses for each license type.
ActualPoolSize	The total number of active licenses currently available for devices and users in the selected license pool. The <code>ActualPoolSize</code> value is the total number of licenses in the pool (<code>PoolSize</code>) value minus the expired licenses (<code>ExpiredLic</code>).
UsedLic	Total number of licenses of each license type reported as used by the licensing clients or licensing server.
RemainingLic	Total number of remaining licensing available in the licensing table.
Warnings	This column displays warnings if licenses have expired, or if licenses used on a per-session basis are no longer sufficient to support the client demand.
FeatureBit	This column indicates whether these license features are enabled or disabled. For more information about enabling a sharable license, see license-pool-profile-root .

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable and config mode on Mobility Conductor.

show license-pool-profile

```
show license-pool-profile [<profile>]
```

Description

Use this command to display a list of license pools, or display the licenses allocated for a specific pool. All managed devices associated to the same Mobility Conductor can share a pool of licenses, comprised of all the sharable licenses added to the Mobility Conductor. However, ArubaOS also allows you to create individual licensing pools at a configuration node, allowing managed devices below that node to share licenses amongst themselves but not with other managed devices.

Parameter	Description
<profile>	<p>(Optional) The name of the profile for which you are creating a local license pool, for example, Northwest. The profile name is limited to 63 characters.</p> <p>NOTE: In ArubaOS 8.0.x releases, the licensing pool profile name was required to be the license pool configuration path. Starting in ArubaOS 8.1, the <code>license-pool-path</code> parameter is introduced to configure the license pool path, and the profile name can be any string of 63 characters or less.</p>

Starting in ArubaOS 8.1, the `license-pool-path` parameter displays the license pool path for the profile, up to 255 characters, for example, `/USA/northwest`.

If you upgrade a legacy ArubaOS deployment to ArubaOS 8.1 or later, the `license-pool-path` parameter is automatically derived from the `license-pool-profile <profile>` name.

You must use the `license add` command to add license keys to the Mobility Conductor before you can allocate sharable licenses to a license pool, or associate a non-sharable license with an individual managed device, then issue the `license-pool-profile-root` command to enable licensing features on Mobility Conductor.

Examples

```
(host)[node] (config) #show license-pool-profile v6cluster

License pool profile "v6cluster"
-----
Parameter                               Value

AP Permanent Licenses AP Expiry License	These two fields show the numbers of permanent and temporary AP licenses.
PEFNG Permanent Licenses PEFNG Expiry License	These two fields show the numbers of permanent and temporary Next Generation Policy Enforcement Firewall (PEFNG) licenses.
RFP Permanent Licenses RFP Expiry License	These two fields show the numbers of permanent and temporary RF Protect (RFP) licenses.
ACR Permanent Licenses ACR Expiry License	These two fields show the numbers of permanent and temporary ArubaOS Advanced Cryptography (ACR) licenses .

Parameter	Description
WebCC Permanent Licenses WebCC Expiry License	These two fields show the numbers of permanent and temporary Web Content Classification (WebCC) licenses.
VIA Permanent Licenses VIA Expiry License	These two fields show the numbers of permanent and temporary Virtual Intranet Access (VIA) licenses.
MM Permanent Licenses MM Expiry License	These two fields show the numbers of permanent and temporary Mobility Conductor licenses in pool.
via-licenses	VIA licenses support Virtual Intranet Access (VIA) or 3rd party VPN client. VIA licenses are not consumed for site-to-site VPNs. If a managed device or standalone controller has a PEFV license, that device will not consume VIA licenses from a licensing pool, as a single PEFV license supports all VIA and 3rd party VPN clients, up to the full user capacity for that device.
webcc-licenses	Add WebCC licenses to the selected pool. The Web Content Classification (WebCC) license is a subscription-based, per-AP license.
eval	(Optional) Include this keyword to add an evaluation license.
<num>	Number of licenses supported by the license key.

show license-pool-profile root

```
show license-pool-profile root
```

Description

Use this command to determine the license types that are enabled and sharable via the root licensing profile. All managed devices associated to the same Mobility Conductor can share a pool of licenses that comprises of all the sharable licenses added to the Mobility Conductor. However, ArubaOS also allows you to create individual licensing pools at a configuration node that allows managed devices below the node to share licenses amongst themselves but not with other managed devices.

You must use the `license add` command to add license keys to the Mobility Conductor before you can allocate sharable licenses to a license pool, or associate a non-sharable license with an individual managed device, then issue the `license-pool-profile-root` command to enable licensing features on Mobility Conductor.

Examples

```
(host) ^[mynode] (config) #show license-pool-profile-root
License root(/) pool profile
-----
Parameter                Value      Set
-----                -
enable PEFNG feature     Enabled
enable RFP feature       Enabled
enable XSEC feature      true
enable ACR feature       true
enable WebCC feature     true
```

show license-usage

```
show license-usage
  acr
  ap
  capacity
  client [pool <pool>] [verbose]
  user
  via
  web-cc
  xsec
```

Description

Display license usage information.

Parameter	Description
acr	Show ACR license usage
ap	Show AP license usage information.
capacity	Show capacity license usage information.
client [pool <pool>] [verbose]	Show license usage for the global configuration pool, or specify a pool name to view license usage within a specific license pool. Use the optional <code>verbose</code> parameter too display aggregated license usage for each configuration node and managed devices in those nodes.
user	Show Policy Enforcement Firewall (PEF) user license usage.
via	Show VIA license usage information.
webcc	Show WebCC license usage information.
xsec	Show Extreme Security (xSec) user and tunnel license usage.

Examples

The following example displays the user license usage.

```
(host) #show license-usage user

User License Usage
-----
Name                Value
-----
```

```

License Limit      2048
License Usage      12
License Available  2036
License Exceeded   0

```

The AP license usage is displayed below:

```

(host) #show license-usage AP

AP Licenses
-----

Total APs                      0

Remaining AP Capacity
-----
Type  Number
----  -
CAPs  509
RAPs  509

```

When you issue the `show license-usage client` command from the CLI of a controller configured as a centralized licensing server, the output displays license usage statistics for each licensing client associated to that server. Include the `verbose` parameter to display license statistics for individual configuration nodes and the devices in those nodes. The output in the example below is separated into multiple tables to better fit in this document. In the ArubaOS CLI, the output appears in a single wide table.

```

(MM) [mynode] #show license-usage client verbose
License Clients License Usage for pool /
-----

```

```

Hostname  IP Address      Mac addr          AP   PEF   RF Protect

The output of the `show license-usage client` command includes the following data columns:

Parameter	Description
Hostname	Name of the licensing client controller.
IP Address	IPv4 or IPv6 address of the licensing client controller.
AP	Total number of AP licenses used by a licensing client associated with this controller.
PEF	Total number of Policy Enforcement Firewall (PEF) licenses used by a licensing client associated with this controller.
RF Protect	Total number of RFprotect licenses used by a licensing client associated with this controller.
ACR	Total number of advanced Cryptography (ACR) licenses used by a licensing client associated with this controller.
WebCC	Total number of Web Content Classification (WebCC) licenses used by a licensing client associated with this controller.
MM	Total number of Mobility Conductor (MM) licenses used by a licensing client associated with this controller.
MC-VA-RW MC-VA-EG MC-VA-IL MC-VA-JP MC-VA-US	Total number of regional licenses required to terminate APs on a virtual controller. Different MC-VA-XX license types enable APs to support regional channels for the following countries: <ul style="list-style-type: none"> ■ MC-VA-US: United states ■ MC-VA-JP: Japan ■ MC-VA-IL: Israel ■ MC-VA-EG: Egypt ■ MC-VA-RW: Rest of the world (all other countries)
Last update (secs. ago)	Time, in seconds, that has elapsed since the licensing table on the licensing client was updated.

Related Commands

Command	Description
license	This command allows you to install, delete, and manage software licenses on Mobility Conductor.
show license aggregate	Display the total number of licenses of each license type in all Mobility Conductor licensing pools.
show license keys	Display information about all installed license keys.

Command	Description
<code>show license box</code>	Display the device-specific licenses used by a managed device.

Command History

Release	Modification
ArubaOS 8.6.0.0	The command output also displayed IPv6 address in <code>IP addressparameter</code> .
ArubaOS 8.4.0.0	The <code>Active MUX</code> and <code>Active PUTN</code> parameters were added.
ArubaOS 8.0.1.0	The <code>verbose</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

show lldp interface

```
show lldp interface gigabitethernet <slot/module/port>
```

Description

This command displays the LLDP interfaces information.

Parameter	Description
gigabitethernet <slot/module/port>	Displays LLDP information on a gigabitethernet interface.

Example

The example shows two commands. The output of the `show lldp interface` command displays information for all LLDP interfaces.

```
(host) #show lldp interface
LLDP Interfaces Information
-----
Interface LLDP TX LLDP RX LLDP-MED TX interval Hold Timer
-----
GE1/3      Enabled Enabled Enabled 30 120
The following example only shows information for the GE1/3 interface.
(host)[node] #show lldp interface gigabitethernet 0/0/3
Interface: gigabitethernet 0/0/3
LLDP Tx: Enabled, LLDP Rx: Enabled
LLDP-MED: Enabled
Transmit interval: 30, Hold timer: 120
```

Parameter	Description
Interface	Name of an LLDP interface.
LLDP TX	Shows if LLDP Protocol Data Unit (PDU) transmission is enabled or disabled.
LLDP RX	Shows if the managed device has enabled or disabled processing of received LLDP PDUs.
LLDP-MED	Shows if LLDP MED protocol is enabled or disabled.
TX interval	The LLDP transmit interval, in seconds.
Hold Timer	The LLDP transmit hold multiplier.

Related Commands

Command	Description
ap lldp profile	Define an LLDP profile that specifies the TLV elements to be sent in LLDP PDUs.

show lldp neighbor

show lldp neighbor interfaces gigabitethernet <slot/module/port> [detail]

Description

This command displays information about LLDP peers.

Parameter	Description
gigabitethernet <slot/module/port>	Displays LLDP information on a gigabitethernet interface.
detail	Include details.

Example

The command in the first example below shows that the ports GE0/0/1 and GE0/0/2 recognize each other as an LLDP peers.

```
(host)#show lldp neighbor
Capability codes: (R)Router, (B)Bridge, (A)Access Point, (P)Phone, (O)Other
LLDP Neighbor Information
-----
Local Intf Chassis ID Capability Remote Intf Expiry-Time (Secs)
-----

MAC: 9c:b7:0d:7d:0b:72: Blacklist
MAC: 7c:d1:c3:d1:02:c8: Blacklist

```

The output of the `show lldp neighbor` command includes the following information:

Parameter	Description
Local Intf	Slot and port number.
Chassis ID	MAC address of the LLDP Peer.
Capability	Shows the capabilities of the peer to operate as a router, bridge, access point, phone or other network device.
Remote Intf	Remote interface.
Expiry-time	Expiry time.
System Name	Name of the peer system, as supplied by the peer.

The output of the `show lldp neighbor interface gigabitethernet <slot/module/port> detail` command varies, depending upon the type of LLDP peer detected. The output in the example above contains the following information:

Parameter	Description
Interface	Name of the port for which you are viewing LLDP neighbor information.
Number of Neighbors	Number of LLDP neighbors seen by the port.
Chassis id	MAC address of the neighbor device.
Management address	MAC address of the neighbor's management port.
Interface description	Description of the LLDP neighbor interface.
ID	Interface ID of the LLDP neighbor interface.
MTU	Maximum Transmission Unit size allowed by the neighbor device in bytes.
Device MAC	Shows the MAC address of the IAP connected to the MAS port.

Parameter	Description
Last Update	Date and time the neighbor device's status changed.
Time to live	Time, in seconds, for which this information is valid.
Expires in	Time, in seconds, before this information is considered invalid.
System capabilities	This column shows the capabilities of the peer to operate as a router, bridge, access point, phone or other network device.
Enabled capabilities	This column if the peer has been actively configured to operate as a router, bridge, access point, phone or other network device.
System name	Name of the peer system, as supplied by the peer.
System description	Description of the peer system, as supplied by the peer.
Auto negotiation	Shows if link auto-negotiation is enabled for the peer interface.
Media attached unit type	This parameter displays additional details about an LLDP-MED device attached to the interface. The specific details depend upon the capabilities of the device.
VLAN	VLAN ID assigned to the peer interface.
pvid	Indicates if the VLAN ID is assigned to the peer access port.
MAC	Shows the MAC address of the rogue AP detected by the Instant AP(IAP), which is blacklisted by the MAS.
LLDP-MED	Shows details for LLDP-MED (Media Endpoint Discovery), if applicable.
Device Type	Type of LLDP-MED device connected to the peer interface.
Capability	Capabilities of the LLDP-MED device connected to the peer interface.

Related Commands

Command	Description

show lldp statistics

```
show lldp statistics gigabitethernet <slot/module/port>
```

Description

This command displays the LLDP statistics information. By default, this command displays LLDP statistics for the entire list of LLDP interfaces. Include a slot/module/port number to display statistics specific to the interface.

Parameter	Description
<code>gigabitethernet <slot/module/port></code>	Displays LLDP information on a gigabitethernet interface.

Example

The example command below shows LLDP statistics for the Gigabit Ethernet interface **0/0/0**.

```
(host) #show lldp statistics interface gigabitethernet 0/0/0

LLDP Statistics
-----
Interface           Received   Unknow TLVs   Malformed   Transmitted
-----
gigabitethernet0/0  1249      0              0           1249
```

The output of this command includes the following information:

Parameter	Description
Interface	Name of an LLDP interface.
Received	Number of packets received on that interface.
Unknown TLVs	Number of LLDP Protocol Data Units (PDUs) with an unknown type-length-value (TLV).
Number of Malformed packets	Number of malformed packets received on that interface.
Transmitted	Number of packets transmitted from that interface.

Related Commands

Command	Description
ap lldp profile	Define an LLDP profile that specifies the TLV elements to be sent in LLDP PDUs.

Command History

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

show local-cert-mac

```
show local-cert-mac
tag <mac>
```

Description

Display the IP, MAC address and certificate configuration of a managed device in a Mobility Conductor/managed device configuration. By default the output of this command shows each managed device's IP and MAC address and the type of certificate used by those managed devices (Custom or Factory). Use the optional `tag` parameter to display information for a managed device only.

Parameter	Description
<code>tag <tag></code>	IP address of the managed device or MAC address of the managed device.

Example

The output of this command shows that two managed devices have a custom certificate installed.

```
(host)[node] # show local-cert-mac
Local Switches configured by Local Certificate
-----
Switch IP of the Local  MAC address of the Local  Cert-Type  CA cert
-----
10.4.62.3                0B:86:F0:12:AC:15          Custom     CAcert
10.4.62.5                00:0B:86:F0:05:60          Custom     Undefined
```

The output of this command includes the following information:

Parameter	Description
Switch IP of the Local	IP address of the managed device.
MAC address of the Local	MAC address of a managed device with a local certificate.
Cert-Type	Type of certificate used by the local managed device. <ul style="list-style-type: none">■ Custom: User-installed, custom certificate■ Factory: Factory-installed certificate
CA Cert	Name of the Certificate Authority (CA) certificate.

Related Commands

Command	Description
local-factory-cert	This command configures the factory-installed certificate for secure communication between a managed device and Mobility Conductor.
local-custom-cert	This command configures a custom certificate for secure communication between a managed device and Mobility Conductor.

Command History

show localip

```
show localip
  tag <local-switch-ip>
```

Description

Displays the IP address and VPN shared key between master/ conductor and local.

Parameter	Description
tag <local-switch-ip>	Displays VPN configuration of a specific local switch.

Example

The output of this command shows the managed device's IP address and shared key between Mobility Conductor and managed devices.

```
(host)[node] # show localip

Local Switches configured by Local Switch IP
-----
Switch IP address of the Local  Key
-----
0.0.0.0                        *****
```

Related Commands

Command	Description

show localipv6

show localipv6

Description

Shows the IP address and preshared key for the managed device on a Mobility Conductor.

Parameter	Description
<tag>	Show VPN configuration of a specific Local Switch or Output Modifiers.

Example

This example shows the IPv4 and IPv6 addresses configured .

```
(host) [mynode] (config) #show localipv6
Local Switches configured by Local Switch IPv6
-----
Switch IPv6 address of the Local  Corres IPv4 address of the Local  Key
-----
2002::1                          1.1.1.1                          *****
```

show local-peer-mac

Syntax

```
show local-peer-mac tag <local-mac-addr>
```

Description

This command is used to display the MAC address used for secure communication based between Mobility Conductor and managed devices.

Parameter	Description
tag <local-mac-addr>	The managed device's MAC address.

Example

Include the optional tag <local-mac-addr>

```
(host) [mynode] (config) #local-peer-mac 00:0c:29:00:00:00 ipsec 123456
```

Related Commands

show local-userdb

```
show local-userdb
  maximum-expiration
  start <offset>
  page <page-size>
  username <username>
  verbose
```

Description

Shows information about user's accounts in the local user database. Issue this command without any parameters to display a general overview of user's accounts in the database. Use the `maximum-expiration` parameter to show how long the account is valid for in minutes. Use the `start <offset>`, `page <page_size>` parameters to control which user account records in the database display initially and the number of account records displayed on a page.

Parameter	Description
<code>maximum-expiration</code>	How long the account is valid, in minutes, in the internal database.
<code>start <offset></code>	Display records starting at a specific database record number defined by the <code><offset></code> parameter.
<code>page <page-size></code>	Number of user entries to display .
<code>username <username></code>	Show data for a specific user.
<code>verbose</code>	Display the following additional details for each database entry. <ul style="list-style-type: none">▪ Full-Name▪ Company▪ Phone▪ Comments▪ Start-Date▪ Creation-Date▪ Sponsor-Fullname▪ Sponsor-Email▪ Sponsor-Dept▪ Opt-Field-1▪ Opt-Field-2▪ Opt-Field-3▪ Opt-Field-4▪ Grantor-Role▪ VLAN▪ NASIP

Example

This example shows the basic summary of user accounts in the database.

```
(host)[node] #show local-userdb maximum-expiration start 5 page 4

local-userdb maximum-expiration 90

User Summary
-----
Name          Password  Role    E-Mail  Enabled  Expiry  Status  Sponsor-
Name Grantor-Name
-----
- -----
guest-0657984  *         guest   Yes     Yes      Active
admin
guest-8330301  *         guest   Yes     Yes      Active
admin
guest-5433352  *         guest   Yes     Yes      Active
admin
guest-3469360  *         guest   Yes     Yes      Active
admin

User Entries: 11
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the user.
Password	The user's password.
Role	Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method.
E-mail	Shows the email address of the user account.
Enabled	Shows whether the account is enabled or disabled.
Expiry	Shows the expiration date for the user account. If this is not set, the account does not expire.
Status	Shows whether the profile has enabled or disabled the ability to use the HTTP protocol to redirect users to the captive portal page.
Sponsor-Name	Shows the sponsor's name.

Parameter	Description
Grantor-Name	Shows the grantor's name.
User Entries	Shows the number of user accounts in the database.

Related Commands

show local-userdb-guest

```
show local-userdb-guest
  maximum-expiration
  start <offset>
  page <page-size>
  username <username>
  verbose
```

Description

Shows information about guest accounts in the local user database. Issue this command without any parameters to display a general overview of guest accounts in the database. Use the `maximum-expiration` parameter to show validity period of the account, in minutes. Use the `start <offset>`, `page <page_size>` parameters to control which guest account records in the database display initially and the number of account records displayed on a page.

Parameter	Description
<code>maximum-expiration</code>	How long the account is valid, in minutes, in the internal database.
<code>start <offset></code>	Display records starting at a specific database record number defined by the <code><offset></code> parameter.
<code>page <page-size></code>	Number of user entries to display .
<code>username <username></code>	Show data for a specific user.
<code>verbose</code>	Display the following additional details for each database entry. <ul style="list-style-type: none">▪ Full-Name▪ Company▪ Phone▪ Comments▪ Start-Date▪ Creation-Date▪ Sponsor-Fullname▪ Sponsor-Email▪ Sponsor-Dept▪ Opt-Field-1▪ Opt-Field-2▪ Opt-Field-3▪ Opt-Field-4▪ Grantor-Role▪ VLAN▪ NASIP

Example

This example shows the basic summary of guest user accounts in the database.

```
(host)[node] #show local-userdb-guest maximum-expiration start 5 page 4
local-userdb-guest maximum-expiration 90

Guest UserSummary
-----
Name          Password  Role   E-Mail  Enabled  Expiry  Status  Sponsor-
Name Grantor-Name
-----
- -----
guest-0657984  *  guest   Yes     Yes     Active

show localip

```
show localip
tag <local-switch-ip>
```

Description

Displays the IP address and VPN shared key between master/ conductor and local.

Parameter	Description
tag <local-switch-ip>	Displays VPN configuration of a specific local switch.

Example

The output of this command shows the managed device's IP address and shared key between Mobility Conductor and managed devices.

```
(host)[node] # show localip

Local Switches configured by Local Switch IP
-----
Switch IP address of the Local  Key
-----
0.0.0.0                        *****
```

Related Commands

Command	Description
localip	This command configures the IP address and preshared key for the managed device on a Mobility Conductor.

Command History

Version	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Configuration mode on Mobility Conductor.

show log

```
show log
  all
  ap-debug
  arm
  arm-user-debug
  errorlog
  network
  peer-debug
  security
  system
  user
  user-debug
  wireless [<number>]
```

Description

Show the log files on Mobility Conductor or a managed device.

Parameter	Description
all	Issue the command <code>show log all</code> to display all log files. Include this parameter after one of the log file types (for example, <code>show log security all</code>) to display all log files of the selected type.
ap-debug	Display AP debug log files.
arm	Display ARM log files.
arm-user-debug	Display ARM user debug log files.
errorlog	Display error log files.
network	Display network log files.
peer-debug	Display peer debug log files.
security	Display security log files.
system	Display system log files.
user	Display user log files.
user-debug	Display user debug log files.
wireless <number>	Display wireless log files.

Parameter	Description
	Include this parameter at the end of the show log command to start displaying the log output from the specified number of lines from the end of the log.

Related Commands

Command	Description
logging	Use this command to specify the IP address of the remote logging server, facility, severity, and the type.
logging-trace-files	The slog_flash application continuously updates log files to the USB storage. An error occurs when the USB storage is removed when the update is in progress. This command is introduced to prompt the user before removing the external USB, to avoid this error.

Command History

Version	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Configuration mode on Mobility Conductor.

show log all

```
show log all [<number>]
```

Description

Shows the log files on Mobility Conductor or a managed device.

Parameter	Description
<number>	Include this parameter at the end of the show log command to start displaying the log output from the specified number of lines from the end of the log.

Example

This example shows the log files on Mobility Conductor or a managed device.

```
(host)[mynode] #show log all

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show log essid-debug

```
show log essid-debug{[<number>][all]}
```

Description

Show the controller's ESSID debug logs. An Extended Service Set Identifier (ESSID) is used to identify the wireless clients and Wireless Broadband Routers in a WLAN. All wireless clients and Wireless Broadband Routers in the WLAN must use the same ESSID.

Parameter	Description
<number>	Start displaying the log output from the specified number of lines from the end of the log.
all	Shows all the ESSID debug logs for the controller.

Related Commands

Command	Description
logging	Use this command to specify the IP address of the remote logging server, facility, severity, and the type.
logging-trace-files	The slog_flash application continuously updates log files to the USB storage. An error occurs when the USB storage is removed when the update is in progress. This command is introduced to prompt the user before removing the external USB, to avoid this error.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command Introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor or managed devices.

show log bssid-debug

```
show log bssid-debug{[<number>][all]}
```

Description

A Basic Service Set Identifier (BSSID) uniquely defines each wireless client and Wireless Broadband Router. This command shows the controller's BSSID debug logs.

Parameter	Description
<number>	Start displaying the log output from the specified number of lines from the end of the log.
all	Shows all the BSSID debug logs for the controller.

Related Commands

Command	Description
logging	Use this command to specify the IP address of the remote logging server, facility, severity, and the type.
logging-trace-files	The slog_flash application continuously updates log files to the USB storage. An error occurs when the USB storage is removed when the update is in progress. This command is introduced to prompt the user before removing the external USB, to avoid this error.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command Introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show logging

```
show logging facility|server|{level [verbose]}
```

Description

The IP address of the remote logging server, as well as facility log types and their associated facility levels.

The ArubaOS logging levels follow syslog convention:

- level 7: Emergency
- level 6: Alert
- level 5: Critical
- level 4: Errors.
- level 3: Warning
- level 2: Notices
- level 1: Informational
- level 0: Debug

The default logging level is **level 1**. You can change this setting via the `logging` command.

Parameter	Description
<code>facility</code>	View the facility used when logging messages into the remote syslog server.
<code>server</code>	Show the IP address of a remote logging server.
<code>level [verbose]</code>	Show logging levels at which the messages are logged. Include the optional verbose parameter to display additional data for logging subcategories and processes.

Example

This example below displays defined logging levels for each logging facility.

```
(host)[node] #show logging level
LOGGING LEVELS
-----
Facility  Level
-----  -
network   warnings
security  warnings
system    warnings
user      warnings
```

```
wireless warnings
```

This example below displays the IP address of a remote log server. If a remote log server has not yet been defined, this command will not display any output.

```
(host)[node] #show logging server
Remote Server: 1.1.1.1

FACILITY MAPPING TABLE
-----
local-facility  severity  remote-facility
-----
user            debugging local1
```

The following example displays the status of the TLS configuration.

```
(NODE) #show logging server
Remote Server: 2.2.2.2 Destination Port: 514
FACILITY MAPPING TABLE
-----
local-facility  severity  remote-facility  CEF Format  BSD RFC 3164
Compliance     source-interface  tls option
-----
---  -----
All      Disabled      debugging local1      Disabled      Disabled
          Disabled      Enabled
```

If the destination port is not configured, the default port 514 will be used for rsyslog to establish the TCP connection. The default facility will be local1. CLI will display error messages if TLS is enabled simultaneously either with source-interface or CEF.

Related Commands

Command	Description
logging	Use this command to specify the IP address of the remote logging server, as well as facility log types and their associated facility levels.

Command History

Version	Description
ArubaOS 8.9.0.0	The output sub-parameter <code>tls</code> was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Configuration mode on Mobility Conductor.

show loginsessions

show loginsessions

Description

Displays the current administrator login sessions statistics.

Example

Issue this command to display the admin login session statistics.

```
Session Table
-----
ID  User Name  User Role  Connection From  Idle Time  Session Time
--  -
1   admin     root      10.100.102.43   00:00:00  00:27:59
```

The output includes the following parameters:

Parameter	Description
ID	Sessions identification number
User Name	Administrator's user name
User Role	Administrator's role
Connection From	The IP address from which the administrator is connecting
Idle Time	Amount of time the user has been idle
Session Time	Total time the session has been open

show mac-address-table

show mac-address-table

Description

Displays a MAC forwarding table.

Example

Issue this command to display the MAC forwarding table.

```
Dynamic Address Count:          0
Static Address (User-defined) Count:      0
System Self Address Count:
Total MAC Addresses :          6
Maximum MAC addresses :          6
MAC Address Table
-----
Destination Address  Address Type  VLAN  Destination Port
-----
00:0b:86:00:00:00   Mgmt        1     vlan 1
00:0b:86:f0:05:60   Mgmt        1     vlan 1
00:0b:86:00:00:00   Mgmt        62    vlan 62
00:0b:86:f0:05:60   Mgmt        62    vlan 62
00:0b:86:00:00:00   Mgmt       4095   vlan 4095
00:0b:86:f0:05:60   Mgmt       4095   vlan 4095
```

The output includes the following parameters:

Parameter	Description
Dynamic Address Count	Count of dynamic addresses currently associated with the managed device.
Static Address (User-defined) Count	Count of static, user-defined addresses associated with the managed device.
System Self Address Count	Number of self system addresses.
Total MAC Addresses	Total number of MAC addresses associated with the managed device.
Maximum MAC Addresses	Maximum number of MAC addresses.
Destination Address	Destination MAC address.

Parameter	Description
Address Type	Destination address type.
VLAN	Associated VLAN.
Destination Port	Destination port.

Related Commands

show master-local stats / show conductor-local stats

```
show master-local stats / show conductor-local stats
  ipv4-addr
  ipv6-addr
  page
```

Description

Display statistics for communication between Mobility Conductor and managed devices. By default, Mobility Conductor and managed devices exchange heartbeat messages every 10 seconds. These heartbeats include a configuration timestamp. If a Mobility Conductor has later timestamp than the managed device, the state of the managed device changes from Update Successful to Update Required.

Parameter	Description
<ipv4-addr>	Include the IPv4 address of a managed device to display statistics of that managed device only.
<ipv6-addr>	Include the IPv6 address of a managed device to display statistics of that managed device only.
<page>	Start displaying the output of this command at the specified page number.

Example

This example below shows statistics for all communications between the Mobility Conductor and the managed devices.

```
(host) [mynode] #show master-local stats / show conductor-local stats

Missed -> HB Req from Local(s)
-----
IPv4 Address IPv6 Address          HB Req HB Resp Cfg Terminate Peer Reset
Total Missed Last Sent Missed
-----
-----
None          2620:11d:6030:11c5::193 9      19      0          0
0              0
Total Switches:1
```

The output of this command includes the following data columns:

Parameter	Description
IPV4 Address	IPv4 address of the managed device.
IPV6 Address	IPv6 address of the managed device.
HB Req	Heartbeat requests sent from the managed device.
HB Resp	Heartbeat responses sent from the Mobility Conductor.
Cfg Terminate	Number of times the managed device has failed to upgrade to a new configuration.
Peer Reset	The number of times the connection to peer is been reset. The connection could reset due to network connectivity problems or when the peer switch reboots.
Total Missed	Total number of heartbeats that were not received by the managed device.
Last Sent Missed	This counter increments if the managed device misses the last heartbeat from the peer managed device. This counter keeps incrementing until the heartbeat message is received from peer.

Command History

Version	Modification
ArubaOS 8.7.0.0	The output of the command was modified to include IPv6 address.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config mode on Mobility Conductor.

show master-l3redundancy/show conductor-l3redundancy

```
show master-l3redundancy/show conductor-l3redundancy
  config-sync <status>
  status
  switches
```

Description

Displays the Layer-3 configuration and database sync status as well as the current status of Layer-3-domain Mobility Conductor redundancy.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
config-sync <status>	Displays Layer-3 configuration and database sync status.
status	Displays current status of Layer-3 domain master/conductor redundancy.
switches	Displays active and standby controllers on both Layer-3 peers.

Examples

The example below executed on the managed device displays the Layer-3 redundancy configuration.

```
(host) [mynode]#show master-l3redundancy/show conductor-l3redundancy
L3 Sync Role:Primary
L3 Redundant Peer IP:10.9.196.154
IKE PSK: 16c591a3789da6eef4420a5fe45967c3f1cf1bc457464244
```

The example below executed on the managed device displays the Layer-3 configuration and database sync status.

```
(host) [mynode] #show master-l3redundancy config-sync status/show conductor-
l3redundancy config-sync
Command applicable only on current Active of L3 Secondary

(host)[mynode]# show database synchronize
```

```
Last L2 synchronization time: Standby not synchronized since last reboot
Last L3 synchronization time: Secondary not synchronized since last reboot
L2 Periodic synchronization is disabled
L3 Periodic synchronization is disabled
Synchronization doesn't include Captive Portal Custom data
```

The example below executed on the managed device displays the health of primary and secondary data centers.

```
(host) [mynode]#show master-l3redundancy status/show conductor-l3redundancy
status
L3 Redundancy Status
-----
Role IP Address Status
----
Conductor 10.9.196.151 Down
Secondary Conductor 10.9.196.152 Up
```

The example below executed on the managed device allows the user to see the Layer-3 redundant peer controller details along with active and standby controller details:

show master-redundancy/show conductor-redundancy

show master-redundancy/show conductor-redundancy

Description

Display the Mobility Conductor's redundancy configuration.

Example

This example below shows the current master/conductor redundancy configuration, including the ID number of the master VRRP virtual router and the IP address of the peer managed device for master/conductor redundancy.

```
(host) [mynode] (config) #show master-redundancy/show conductor-redundancy
Master/Conductor redundancy configuration:
  VRRP Id 120 current state is MASTER
  Peer's IP Address is 10.17.65.117
  Peer's IPSEC Key is *****
```

Description

This command displays the used and available memory on Mobility Conductor. Include a process name to display a memory information for a process on the AP or Mobility Conductor.

Use this command under the supervision of Aruba technical support to help debug process errors. Include the name of a process to show memory information for that process.

The optional output modifiers `| begin` , `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
aaa	Displays memory information for the AAA process.
amon_recvr	Displays the memory information for the amon_recvr process.
amon_sender	Displays the memory information for the amon_sender process
ap	Displays memory information for a process running on a specific AP or BSSID. <ul style="list-style-type: none"> ▪ ble_daemon: Displays the memory information for the ble_daemon process. ▪ lldpd: Displays the memory information for the LLDP process. ▪ meshd: Displays the memory information for the meshd process.

Parameter	Description
	<ul style="list-style-type: none"> ▪ ofald: Displays the memory information for the OpenFlow Agent Lite Daemon process. ▪ raper: Displays the memory information for the rapper process. ▪ rfd: Displays the memory information for the rfd process. ▪ sapd: Displays the memory information for the sapd process. ▪ stm: Displays the memory information for the AP stm process. ▪ wcd: Displays the memory information for the AP wcd process.
apimagemgr	Displays the memory information for the apiimagemgr process.
apprf	Displays the memory information for the AppRF process.
arcli-helper	Displays the memory information for the aruba-central process.
arm	Displays the memory information for the ARM process.
aruba-central	Displays the memory information for the ARM process.
as_visibility	Displays the memory information of Air Slice visibility process.
auth	Displays the memory information for the authentication process.
ble_daemon_s	Displays the memory information for the ble-daemon process on the controller..
ble_relay	Displays the memory information for the ble relay process.
blmgr	Displays the memory information for the blmgr process.
certmgr	Displays the memory information for the certmgr process.
cfgdist	Displays the memory information for the cfgdist process.
cfgm	Displays the memory information for the cfgm process.
cli	Displays the memory information for the cli process.
cluster_mgr	Displays the memory information for the cluster_mgr process.

Parameter	Description
cluster_upgrade_mgr	Displays the memory information for the cluster_upgrade_mgr process.
cpsec	Displays the memory information for the cpsec process.
ctamon	Displays the memory information for the ctamon process.
ctrlmgmt	Displays the memory information for the ctrlmgmt process.
dbsync	Displays the memory information for the dbsync process.
dds	Displays the memory information for dds process.
debug	Displays detailed memory information to debug memory errors.
dhcpcd	Displays the memory information for the DHCP process.
dhcpcdwrap	Displays the memory information for the dhcpcdwrap process.
dot1x1	Displays the memory information for the dot1x1 process.
dpagent	Displays the memory information for the DPagent process.
ecc	Displays the DRAM ecc counters.
fpapps	Displays the memory information for the fpapps process.
fw_visibility	Displays the memory information for the fw_visibility process.
gsmmgr	Displays the memory information for gthe smmgr process.
ha_mgr	Displays the memory information for the HA_MGR process.
im_helper	Displays the memory information for the im_helper process.
ip_flow_export	Displays the memory information for the ip flow export process.
isakmpd	Displays the memory information for the isakmpd process.
l2tpd	Displays the memory information for the l2tpd process.
lagm	Displays the memory information for the lagm process.
licensemgr	Displays the memory information for the licensemgr process.
lldpd	Displays the memory information for the lldpd process.
mdns	Displays the memory information for the mDNS process.

Parameter	Description
mobileip	Displays the memory information for the mobileip process.
mon_serv	Displays the memory information for the mon_serv process.
mon_serv_fwv	Displays the memory information for the mon_serv_fwv process.
nbapi	Displays the memory information for the nbapi process.
ofa	Displays the memory information for the OpenFlow Agent process.
off-loader	Displays the memory information for the off-loader process.
ospf	Displays the memory information for the OSPF process.
pdm	Displays the memory information for the Policy Domain Manager process.
phonehome	Displays the memory information for the phonehome process.
pim	Displays the memory information for the pim process.
pptpd	Displays the memory information for the pptpd process.
profmgr	Displays the memory information for the profmgr process.
rtpa	Displays the memory information for the rtpa process.
sdwan	Displays the memory information for the sdwan process.
slb	Displays the memory information for the slb process.
snmpd	Displays the memory information for the snmpd process.
stm	Displays the memory information for the stm process.
syslogdwrap	Displays the memory information for the syslogdwrap process.
tm	Displays the memory information for the telemetry manager process.
tunneled_node_mgr	Displays the memory information for the tunneled_node_mgr process.
ucm	Displays the memory information for the UCM process.
udbserver	Displays the memory information for the udbserver process.

Parameter	Description
upgrademgr	Displays the memory information for the upgrademgr process.
user_visibility	Displays the memory information for the user_visibility process.
vrrp	Displays the memory information for the vrrp process.
web_cc	Displays the memory information for the WebCC process.
wms	Displays the memory information for the WMS process.
wpa3_sae	Displays the memory information for the wpa3_sae process.

Example

The command `show memory` displays, in Kilobytes, the total memory on Mobility Conductor, the amount of memory currently being used, and the amount of free memory.

```
(host) [mynode] #show memory

Memory (Kb): total: 256128, used: 162757, free: 93371
```

Include the name of a process to show memory statistics for that process. The example below shows memory statistics for **mobileip**.

```
(host) [mynode] #show memory mobileip

The output of this command includes the following columns:

Column	Description
Type	The <code>show memory</code> command only shows information for predefined processes, so this column always displays the parameter <code>default</code> .
Num Alloc	Current number of memory allocations.
Size Allocs	Total size of all memory allocations, in bytes.
Peak Allocs	Maximum number of allocations used throughout in the life of the process.
Peak Size	Maximum size of allocations used throughout in the life of the process, in bytes.
PC	Program counter (PC) is the address of a memory allocation. (For internal use only)

Column	Description
Allocs	Number of memory allocations at that program counter. (For internal use only)
Size	Size of all memory allocations at that program counter. (For internal use only)

Command History

Release	Modification
ArubaOS 8.10.0.0	The <code>tm</code> parameter was added.

show mgmt-servers

show mgmt-servers

Description

Displays list of management servers that receive Advanced Monitoring (AMON) messages from the controller.

Parameter	Description
mgmt-servers	Management Servers. This could be AirWave Management Server or any other server that receive messages from the controller using AMON protocol.

Example

The output of this command shows list of management servers.

```
(host) (mynode) #show mgmt-servers
List of Management Servers
-----
Primary Server  Profile      Transport-method
-----
2001::2        default-amp  secure-udp
40.40.40.1     default-amp  secure-udp
10.1.1.11      default-amp  udp
20.16.11.1     default-ale  udp
Num Rows:4
Starting from ArubaOS 8.9.0.0, the output of this command is modified as follows:
(host) (mynode) #show mgmt-servers
List of Management Servers
-----
Primary Server  Profile      Transport-method  Server Status
-----
10.9.217.71    default-controller  udp               conductor
Num Rows:1
```

Related Commands

Command	Description

show mgmt-user

```
show mgmt-user <username>
  audit-info <username>
  console <username>
  local-authentication-mode <username>
  ssh-pubkey <username>
  webui-cacert <username>
  <username>
```

Description

Displays the list of management users on the controller and the details of each management user.

Parameter	Description
audit-info	Displays the audit information related to a specified management user.
console	Displays the serial console status of a management user.
local-authentication-mode	Displays the status of the local-authentication mode.
ssh-pubkey	Displays the number of management users using the ssh-pubkey.
webui-cacert	Displays the number of management users using web CA certificates.
username	Displays the details of a specified management user. Starting from ArubaOS 8.10.0.0, the range of characters in the username is increased from 1-64 to 1-128.

Example

The output of this command shows the client certificate name, username, user role, and revocation checkpoint for management users using the ssh-pubkey in the controller.

```
#show mgmt-user ssh-pubkey

SSH Public Key Management User Table
-----
CLIENT-CERT          USER          ROLE          STATUS          REVOCATION
CHECKPOINT Max-concurrent-sessions

show mon-serv ap-microboot-stats

show mon-serv ap-microboot-stats

Description

This command displays the AP micro-bootstrapping statistics.

Example

The following example displays the AP micro-bootstrapping statistics.

```
(host) [mynode] #show mon-serv ap-microboot-stats
ENTRY MISSING (STATS) 0
ENTRY (WAIT STATE) 0
ENTRY (WAIT TO READY STATE) 0
ENTRY (READY STATE) 0
ENTRY (CREATED BY AMON) 0
ENTRY (CREATED BY BOOTSTRAP) 0
ENTRY (CREATED BY MICROBOOT) 0
ENTRY (PARENT MISSING) 0
ENTRY (PARENT IN WAIT STATE) 0
ENTRY (PARENT IN READY STATE) 0
ENTRY (PARENT UNKNOWN) 0
ENTRY (DELETED IN WAIT STATE) 0
ENTRY (DELETED IN READY STATE) 0
ENTRY (WITH CHILD WAITLIST CREATED) 0
ENTRY (WITH CHILD WAITLIST REMOVED IN READY STATE) 0
ENTRY (WITH CHILD WAITLIST REMOVED IN WAIT STATE) 0
ENTRY (MICROBOOT REQUEST SENT) 0
ENTRY (MICROBOOT REQUEST RECVD) 0
ENTRY (MICROBOOT REQUEST RECVD FOR DELETED ENTRY) 0
ENTRY (DELETED BY CLEANUP) 0
ENTRY (DELETED BY AGING) 0
ENTRY (DELETED BY AMON) 0
ENTRY (DELETED BY MON) 0
ENTRY (EXTRA INFO RACE CONDN) 0
ENTRY (LIST INSERT FAILED) 0
ENTRY (LIST REMOVE FAILED) 0
ENTRY (PARENT MISSING IN BULK BOOTSTRAP) 0
ENTRY (MULTIPLE MICROBOOT RESPONSE RECVD) 0
```

show mon-serv device-count

show mon-serv device-count

Description

This command displays a count of devices that are added or deleted.

Example

The following example shows a count of devices that are added or deleted.

```
(host) [mynode] #show mon-serv device-count
Num Ap Added                0
Num Ap Deleted              0
Num Ap Xml Req              0
Num Radio Added             0
Num Radio Deleted           0
Num Radio Xml Req           0
Num Vap Added               0
Num Vap Deleted             0
Num Vap Xml Req             0
Num Sta Added               59
Num Sta Deleted             89
Num Sta Xml Req             0
```

ENTRY (MULTIPLE MICROBOOT RESPONSE RECVD) 0
```

Command History

Release	Modification
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show mon-serv-global-hash-tbl

```
show mon-serv-global-hash-tbl
  ap { counts | entries }
  mesh-table { counts | entries }
  vap { counts | entries }
```

Description

This command displays the global hash table entries of the monitoring server.

The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
<code>ap</code>	Displays the global AP hash table.
<code>mesh-table</code>	Displays the global mesh hash table.
<code>vap</code>	Displays the global VAP hash table.
<code>counts</code>	Displays the counts of entries in global hash table of the managed device.
<code>entries</code>	Displays the global hash table entries. Use this parameter only for the purpose of debugging.

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show mon-serv-fwv-lc-table

```
show mon-serv-fwv-lc-table
  airgroup
  bootstrap-stats <ip-addr>
```

Description

This command shows the status of local controllers and AirGroup counters on the monitoring server.

The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
<code>airgroup</code>	Displays the AirGroup counters.
<code>bootstrap-stats <ip-addr></code>	Displays the bootstrapping statistics.

Example

The following example shows the counter statistics on the controller.

```
(host) [mynode] #show mon-serv-fwv-lc-table airgroup

MON_SERV Airgroup Table
-----
LC IP          Servers  Users  Server Usage  User Usage  Server Ip Entries
User Ip Entries  Ag sessions  Mode
-----
-----
10.15.20.40  0         1      1364          1          1365          2
                0
10.15.20.41  5         0       4             0           4             0
                0
10.15.20.24  5         3       4             3           5             4
                0
Total        10        4      1372          4          1374
```

Related Commands

Command	Description
mon-serv-toggle-amon-traffic-filter	This command enables AMON traffic filter.

Command History

show mon-serv-lc-table

```
show mon-serv-lc-table
  bootstrap-stats <ip-addr>
  debug
  dev-del-stats <ip-addr>
  microboot-stats <ip-addr>
```

Description

This command shows the status and counters of monitoring server.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
bootstrap-stats <ip-addr>	Shows bootstrap statistics for an lc-cluster.
debug	Shows the debug LC controller.
dev-del-stats <ip-addr>	Shows (STM) device delete reason statistics for an lc-cluster.
microboot-stats <ip-addr>	Shows micro-bootstrapping statistics and threshold counts for an lc-cluster.

Example

The following example shows the configuration status of all branch config groups on the controller.

```
(host) [mynode] #show mon-serv-lc-table airgroup
MON_SERV Local Controllers Table
-----
LC IP          BootStrap Status  AP Count Up  AP Count Down  Radio Count  VAP
Count  User Count
-----  -----
-----

show mon-serv-mesh-tbl-entry

```
show mon-serv-mesh-tbl-entry <dev-key> 2G | 5Gall | 5Glower | 5Gmiddle | 5Gupper |
6G | 60G [child-list]
```

Description

This command displays the mesh table entries of the monitoring server.

The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
<code>dev-key</code>	The MAC address of the AP.
<code>2G</code>	Displays the entries of 2 GHz radio band.
<code>5Gall</code>	Displays the entries of 5 GHz radio band.
<code>5Glower</code>	Displays the entries of lower 5 GHz radio band.
<code>5Gmiddle</code>	Displays the entries of middle 5 GHz radio band.

Parameter	Description
5Gupper	Displays the entries of higher 5 GHz radio band.
6G	Displays the entries of 6 GHz radio band.
60G	Displays the entries of 60 GHz radio band.
child-list	If you include this optional parameter, the output of this command will include the mesh table entries of the child node.

Command History

Release	Modification
ArubaOS 8.10.0.0	The 6G parameter was introduced.
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show neighbor devices

```
show neighbor devices
  cdp-statistics
  interface
```

Description

Show neighbor device information.

Parameter	Description
cdp-statistics	Displays CDP RX statistics.
interface	Displays neighbor information on the interface.

Example

The command in the first example below shows that the managed device recognizes two neighbor devices.

```
[host] (node) # show neighbor devices
Interface objtype is 7
Capability codes: (R)Router, (B)Bridge, (A)Access Point, (P)Phone,
(S)Station
(r)Repeater, (O)Other
Neighbor Devices Information
-----
Local Intf      Chassis ID          Capability  Remote Intf  Expiry-Time (Secs)
System
-----
-----
0/0/1           00:0b:86:6a:25:40   B:R        0/0/17       105           Aruba 7220
0/0/2           00:0b:86:6a:25:40   B:R        0/0/18       105           Aruba 7220
```

Parameter	Description
Local Intf	Slot and port number of the local interface that detected the neighbor devices.
Chassis ID	MAC address of the neighbor device.
Capability	Shows the capabilities of the neighbor device to operate as a router, bridge, access point, phone or other network device.
Remote Intf	Slot and port number of the remote interface on the neighbor device

Parameter	Description
Expiry-time	Expiry time.
System Name	Name of the neighbor device, as supplied by the neighbor.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command Introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on managed devices. This command is not supported on Mobility Conductor.

show netdestination

```
show netdestination {ipv4 | ipv6 | <netdestination name>} [verbose]
```

Description

Displays IPv4 and IPv6 network destination information.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
ipv4	Displays IPv4 network destinations.
ipv6	Displays IPv6 network destinations.
<netdestination name>	Displays the name or IP addresses.
verbose	Prints the netdestination table entries.

Example

Issue this command to display all netdestination configured on this managed device. The output below displays information for all configured IPv4 and IPv6 netdestinations. To display additional detailed information for an individual netdestinations, include the name of the netdestination at the end of the command.

```
(host) [mynode] #show netdestination
Name: sep23-ipv4
Destination ID: 34
Position  Type  IP addr  Mask-Len/Range
-----  ---  -
1         host  1.1.1.1  32
2         name  0.0.0.8  google.com
```

The output includes the following parameters:

Parameter	Description
Name	Network destination name.
Destination ID	Network destination ID.
Position	Network destination position.

Parameter	Description
Type	Network destination type.
IP_addr	IP address of the network destination.
Mask-Len/Range	Network destination subnet mask and range. If the netdestination object has a defined domain or host name, that value will appear in the mask-Len or Range column.

Related commands

Command	Description
netdestination	This command configures an alias for an IPv4 network host, subnetwork, or range of addresses.
netdestination6	This command configures an alias for an IPv6 network host, subnetwork, or range of addresses.

Command History

Version	Modification
ArubaOS 8.2.1.0	The <code>Destination ID</code> parameter was added to the output.
ArubaOS 8.2.0.0	The <code>ipv4</code> and <code>ipv6</code> parameters were added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	You must have a PEFNG license to configure or view a netdestination.	Enable or Config mode on Mobility Conductor.

show netexthdr

show netexthdr <alias-name>

Description

This command displays the IPv6 extension header (EH) types that are denied.

Parameter	Description
<alias-name>	Specify the EH alias name.

Example

The following command displays the denied extended header types in the default EH:

```
(host)[mynode] #show netexthdr default
Extended Header type(s) Denied
-----
51,
```

Related Commands

Command	Description
netexthdr	This command allows you to edit the packet filter options in the extension header (EH).

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show netservice

```
show netservice [<string>]
```

Description

Show network services.

Issue this command without the optional `<string>` parameter to view a complete table of network services on the controller. Include the `<string>` parameter to display settings for a single network service only.

Parameter	Description
<code><string></code>	Name of a network service.

Example

The following example shows the protocol type, ports and application-level gateway (ALG) for the DHCP service.

```
(host)[mynode] #show netservice svc-dhcp
Services
-----
Name      Protocol  Ports  ALG  TYPE
----      -
svc-dhcp  udp       67-68  dhcp
```

Related Commands

Command	Description
netservice	This command configures an alias for network protocols.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show ntp

```
show ntp
  authentication-keys
  events                NTP clock transition information
  peer                  NTP Peer Info
  servers               NTP Server Info
  status                NTP Information
  trusted-keys
```

Description

Shows NTP related information.

Parameter	Description
authentication	Displays the NTP authentication key information.
events	Displays the NTP clock transition information.
peer	Displays the NTP peer information.
servers	Displays the NTP server information.
status	Displays the NTP status information.
trusted-keys	Displays the NTP trusted keys information.

Related Commands

Command	Description
ntp	Helps configure NTP authentication keys.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show ntp authentication-keys

```
show ntp authentication-keys
```

Description

Show information for the NTP authentication key.

The following example shows values for the NTP authentication keys—Key ID, Key Type, and the Secret.

```
(host) [mynode] # show ntp authentication-keys
Key Id Key Type Secret
-----
41      sha1      *****
```

The output of this command includes the following parameters:

Parameter	Description
Key ID	The key identifier used when you configured the NTP authentication key.
Key Type	The key type that you used when you configured the NTP authentication key—md5 or sha1.
Secret	The key value for the MD5/SHA1 hash used when you configured the NTP authentication key.

Related Commands

Command	Description
ntp	Helps configure NTP authentication keys.

Command History

Release	Modification
ArubaOS 8.2.1.0	The output was modified to show the SHA1 key type and secret (in encoded format), when SHA1 authentication is configured.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show ntp events

show ntp events

Description

Shows NTP clock transition information.

Example

The following example displays the output of the `show ntp events` command.

```
(host)[mynode] #show ntp events

Mon, Oct 19 2020 10:26:07.495 System clock "Mon, Oct 19 2020

show ntp peer

```
show ntp peer <fqdn/ip/ip6 Address>
```

Description

Show NTP peer information.

The `show ntp peer` command is used for NTP server troubleshooting, and should only be used under the supervision of Aruba technical support. Issue the [show ntp servers](#) command to view basic settings for currently configured NTP servers.

Parameter	Description
fqdn	Fully Qualified Domain Name of NTP Server.
ip	IPv4 address of NTP Server.
ip6	Pv6 address of NTP Server.

Example

The output of this commands shows IPv4 and IPv6 address of the peer.

```
(host)[mynode]#show ntp peer 2008::2

Related Commands

Command	Description
ntp	This command configures a Network Time Protocol (NTP) server.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config mode on Mobility Conductor.

show ntp servers

show ntp servers [brief]

Description

Show information for Network Time Protocol (NTP) servers.

Parameter	Description
brief	Display the IP address of the defined NTP servers, iburst and key settings.

Examples

The following example shows values for the primary and backup NTP servers. The primary server is marked with an asterisk (*) and the backup server is marked with an equals sign (=). Note that a backup server will not display delay, offset or dispersion data, as it is not currently in use.

```
(host) (config) #show ntp server
NTP Server Table Entries
-----
Flags:      * Selected for synchronization
+ Included in the final selection set
# Selected for synchronization but distance exceeds maximum
- Discarded by the clustering algorithm
= mode is client
remote                local      st    poll  reach  delay
offset      disp
=====
*2012::d63d:7eff:fe46:7309    2012::40      3 1024    377    0.00169
-0.001367    0.13815
```

The output of this command includes the following parameters:

Parameter	Description
flags	The flags indicate the status of the server.
remote	IP address of the remote NTP server defined using the CLI command ntp .
local	IP address of the local clock.

Parameter	Description
st	NTP uses hierarchical levels of clock sources, or strata, and assigns each layer a number starting with zero at the root. The st column in the output of this command represents the number of servers between the configured NTP server and the root reference clock.
poll	Interval, in seconds, between the local NTP server's attempt to poll the remote NTP server.
reach	An index that measures whether or not the remote NTP server could be reached at eight most recent polling intervals. If the NTP server has just been configured and hasn't yet been polled successfully, the value will be zero (0). A value of 377 indicates that the last eight poll queries were successful.
delay	Delay, in seconds, between the time that the local clock polls the NTP server and the NTP server returns a reply.
offset	The difference in time, in seconds, between the local clock and the NTP server.
disp	Dispersion represents the maximum error of the local clock relative to the reference clock, and is a measurement of the time server and network quality. Lower dispersion values are preferred over higher dispersion values.

The following example shows the **ntp servers** configuration. The NTP server IP address, key ID and iburst status are shown when the `ntp servers brief` command is used.

The following output is for IPv4:

```
(host) (config) #show ntp servers brief
server 1.1.1.1 key 1234
server 10.1.1.245 iburst key 12345
```

The following output is for IPv6:

```
(host) (config) #show ntp servers brief
server 2012::d63d:7eff:fe46:7309
```

show ntp status

show ntp status

Description

Show information for a NTP server.

Example

The following example shows values for the primary NTP server.

```
(host) #show ntp status

Authentication:          enabled
time since restart:     2347
time since reset:       7594
packets received:       4
packets processed:      0
current version:        0
previous version:       0
declined:               0
access denied:          0
bad length or format:   0
bad authentication:     0
rate exceeded:          0
system peer:            10.1.1.250
system peer mode:       client
leap indicator:         00
stratum:                3
precision:              -18
root distance:          0.03236 s
root dispersion:        0.06728 s
reference ID:           [10.1.1.250]
reference time:         cd45b701.bcbc05d5 Tue, Feb 17 2009 14:21:53.737
system flags:           auth monitor ntp kernel stats
jitter:                 0.005020 s
stability:              0.866 ppm
broadcastdelay:         0.003998 s
authdelay:              0.000000 s
```

The output of this command includes the following parameters:

Parameter	Description
authentication	Indicates if authentication is enabled for the NTP server.
time since restart	Time in hours since the system was last rebooted.

Parameter	Description
time since reset	The number of seconds since the last time the local NTP server was restarted.
packets received	Total number of packets received.
packets processed	Number of packets received in response to previous packets sent.
current version	Number of packets matching the current NTP version.
previous version	Number of packets matching the previous NTP version.
declined	Number of packets declined.
access denied	Number of packets for which access has been denied.
bad length or format	Number of packets with invalid length, format or port number.
packets received	Total number of packets received.
bad authentication	Number of NTP packets that failed to be authenticated.
rate exceeded	Number of packets discarded due to rate limitation.
system peer	The IP address of the peer NTP server.
system peer mode	The peer mode of this remote association: <ul style="list-style-type: none"> ▪ Symmetric Active ▪ Symmetric Passive ▪ Client ▪ Server ▪ Broadcast
leap indicator	This parameter indicates whether or not a leap-second should be inserted or removed at the end of the last day of the current month. <ul style="list-style-type: none"> ▪ 00 no warning ▪ 01 +1 second (following minute has 61 seconds) ▪ 10 -1 second (following minute has 59 seconds)
stratum	The stratum level of the peer
precision	The advertised precision of the switch. This value can range from -4 and -20, inclusive.
root distance	Total round trip delay to the stratum 1 reference clock.

Parameter	Description
root dispersion	Total dispersion to the stratum 1 reference clock. This value is a cumulative measure of all errors associated with the network hops and servers between the NTP server and its stratum 1 server.
reference ID	IPv4/IPv6 address of the remote NTP server. NOTE: When NTP server is reachable through IPv4 address, use the address as is. If done through IPv6 address, the Reference ID is calculated instead of directly taking the IPV6 address on the NTP Server. The controller performs a MD5 checksum and the last 4 bytes are considered as the reference ID.
reference time	Time when the local system clock was last set or corrected, in NTP timestamp format.
system flags	This parameter displays any flags configured for this NTP entity.
jitter	The average magnitude of jitter between several time queries.
stability	The average magnitude of offset between several time queries
broadcastdelay	The broadcast delay of this NTP server association, in seconds.
authdelay	The authentication delay of this NTP server association, in seconds.

show netstat

```
show netstat
ip dst|src <ip-addr>
port dst|exclude|src <port>
raw
stats
tcp
udp
unix
```

Description

Show network statistics for current active network connections, filtered by protocol type.

Issue the `show netstat stats` command to display aggregate statistics, or protocol type, port or IP address to filter the statistics displayed in the output of this command.

Parameter	Description
<code>ip dst src <ip-addr></code>	Displays network statistics filtered based on the source or destination IP address
<code>port dst exclude src <port></code>	Displays network statistics filtered based on the source or destination port number. Use the <code>exclude</code> parameter to exclude a part from the output of this command.
<code>raw</code>	Show netstat raw socket statistics
<code>stats</code>	Show a network statistics summary
<code>tcp</code>	Displays network statistics for TCP sockets.
<code>udp</code>	Displays network statistics for UDP sockets.
<code>unix</code>	Displays network statistics for UNIX sockets.

Example

The following example shows incoming and outgoing packet statistics for the controller.

```
(host)[node](config) #show netstat stats
Total: 1128 (kernel 1200)
TCP: 147 (estab 82, closed 22, orphaned 0, synrecv 0, timewait 13/0),
ports 0
Transport Total IP IPv6
* 1200 - -
RAW 1 1 0
UDP 240 43 197
```

TCP	125	107	18
INET	366	151	215

show openflow

```
show openflow
  capabilities
  controller
  debug
  flow-table
  flows
  ports
  statistics
```

Description

The command displays the information such as flows, flow tables, system capabilities, and statistics related to OpenFlow on the managed device where OpenFlow is enabled.

Parameter	Description
capabilities	Displays the OpenFlow system capability information.
controller	Displays the OpenFlow Controller information.
debug {ap-client event flows ports}	Displays the debug information for the OpenFlow AP clients, events, flows and ports.
flow-table	Displays the flow table information.
flows	Displays the flow information of the OpenFlow agent.
ports	Displays all the ports configured for OpenFlow.
statistics	Displays the OpenFlow statistics information.

Example

The following command displays the OpenFlow capabilities on the managed device:

```
(host-md) #show openflow capabilities

Match Fields:
In Port
Ethernet Destination Address
Ethernet Source Address
Ethernet Frame Type
802.1Q Vlan ID
IP Protocol
IPv4 Source Address
IPv4 Destination Address
TCP Source Port
```

```

TCP Destination Port
UDP Source Port
UDP Destination Port
IPv6 Source Address
IPv6 Destination Address
Actions:
Output to Port
Set 802.1Q Vlan ID
Set 802.1Q Vlan Priority
Strip 802.1Q Vlan
Set Ethernet Source Address
Set Ethernet Destination Address
Set IPv4 Source Address
Set IPv4 Destination Address
Set DSCP Bits
Set TCP/UDP Source Port
Set TCP/UDP Destination Port

```

The following command displays the OpenFlow Controller information from the managed device:

```

(host-md) #show openflow controller

Controller IP Address: 10.4.131.169  Port: 6633
Connection: UP
State: ACTIVE
Local IP: 10.4.135.67
Local Port: 39703
Last Connected: Tue Jun 21 15:33:45 2016 (83618 seconds ago)
Datapath ID: 00:00:00:0b:86:bb:cd:27
Auxiliary Channel Status:On, Last Connected: Tue Jun 21 15:35:15 2016
Total Flow Count: 25
Total Port Count: 12
Total Packet In Count: 3650
Total Packet In Count (no match): 2
Total Packet Out Count: 7859

```

The following command displays the ports configured for OpenFlow:

```

(host-md) #show openflow ports

Total number of ports: 12

  summary [dpid <dp-id>]
  switches [details]
```

Description

The command displays the OpenFlow Controller configuration information on . In addition, you can view information such as flows, flow tables, hosts, and statistics related to OpenFlow Controller on Mobility Conductor.

Parameter	Description
applications	Displays the application information.
flow-table [app-name dpid sorted-by-dpid]	Displays the flow table information on Mobility Conductor. You can also filter the view based on the application name that installed the flow, or by datapath ID of the OpenFlow instance.
flows [app-name <name> dpid <dp-id>]	Displays the flow information of the OpenFlow Controller on Mobility Conductor.
forwarding-db	Displays data per client for the forwarding database.
hosts [dpid <dp-id> ip-address <ip> mac-address <mac>]	Displays the OpenFlow host configuration information on Mobility Conductor. You can also filter the view by datapath ID, IP address or MAC address of the host.

Parameter	Description
links [dpid <dp-id>]	Displays the OpenFlow links on Mobility Conductor. You can also filter the output based on the datapath ID of the OpenFlow instance.
ports [dpid <dp-id>]	Displays the OpenFlow ports configured on Mobility Conductor. You can also filter the output based datapath ID of the OpenFlow instance.
resource	Displays the OpenFlow resource usage information on Mobility Conductor.
statistics [process-name <name>]	Displays the OpenFlow statistics information. You can also filter the output based on any of the following process names: <ul style="list-style-type: none"> ■ flow_manager ■ topology ■ topology_discovery ■ routing_switch ■ switch_manager ■ packetin_dispatcher ■ event_dispatcher
summary [dpid <dp-id>]	Displays the OpenFlow summary information on Mobility Conductor. You can also filter the output based datapath ID of the OpenFlow instance.
switches [details]	Displays the details of the OpenFlow switches on Mobility Conductor.

Example

The following command displays the OpenFlow Controller configuration details on Mobility Conductor:

```
(host) [mynode] #show openflow-controller
openflow-controller
-----
Parameter          Value      Set
-----          -
ofc state           Enabled
```

```
ofc host-ageout-time      300
ofc mode                  passive
ofc certificate-file      none
ofc key-file              none
ofc ca-certificate-file   none
ofc tls                   Disabled
ofc port                  6633
ofc topology-discovery    Disabled
ofc auxiliary-channel-port 6633
```

show openflow-controller flow-table

```
show openflow-controller flow-table
  app-name
  dpid
  sorted-by-dpid
```

Description

The command displays the flow table information on Mobility Conductor. You can also filter the view based on the application name that installed the flow, or by datapath ID of the OpenFlow instance.

Parameter	Description
app-name	Displays the name of app that installed the flow.
dpid	The dpid of the switch.
sorted-by-dpid	List of applications sorted by dpid.

Example

The following command displays the flow table information for the routing_switch app:

```
(host) [mynode] #show openflow-controller flow-table app-name routing_switch

show openflow-controller

```
show openflow-controller flows
  app-name <name>
  dpid <dp-id>
  flow-cookie
  flow-id
```

Description

The command displays the flow information of the OpenFlow Controller on Mobility Conductor.

Parameter	Description
app-name <name>	Displays the name of app that installed the flow.
dpid <dp-id>	The dpid of the switch.
flow-cookie	Displays the dump flow by a specified cookie.
flow-id	Displays the dump flow by a specified flow-id.

Example

The following command displays the OpenFlow Controller flows details on Mobility Conductor:

```
(host) [mynode] #show openflow-controller flows
Flow 1 :

show openflow-controller hosts

```
show openflow-controller hosts
  dpid <dp-id>
  ip-address <ip>
  mac-address <mac>
```

Description

The command displays OpenFlow host configuration information on Mobility Conductor. You can also filter the view by datapath ID, IP address or MAC address of the host.

Parameter	Description
dpid <dp-id>	Displays the dpid of the switch.
ip-address <ip>	Displays the ip address of the host.
mac-address <mac>	Displays the mac address of the host.

Example

The following command displays the OpenFlow Controller hosts details on Mobility Conductor:

```
(host) [mynode] #show openflow-controller hosts
Hosts
-----
IP          MAC          Wireless  Dpid
  Port No  Port MAC
--          ---          -
-----

show openflow-controller links

```
show openflow-controller links  
  dpid <dp-id>
```

Description

The command displays OpenFlow links on Mobility Conductor. You can also filter the output based on the datapath ID of the OpenFlow instance.

Parameter	Description
dpid <dp-id>	Displays the dpid of the switch.

Example

The following command displays the OpenFlow Controller links details on Mobility Conductor:

```
(host) [mynode] #show openflow-controller links  
Links  
-----  
From Dpid                From Port  To Dpid                To Port  Status  
-----

show openflow-controller statistics

```
show openflow-controller statistics
  process-name <name>
```

Description

The command displays the OpenFlow statistics information. You can also filter the output based on any of the following process names - flow_manager, topology, topology_discovery, routing_switch, switch_manager, packetin_dispatcher, and event_dispatcher.

Parameter	Description
process-name	Displays the OpenFlow statistics information for the process selected.

Example

The following command displays the OpenFlow Controller statistics details on Mobility Conductor:

```
(host) [mynode] #show openflow-controller statistics
Debug-stats
-----
Process-name      Counter-name      Value  Current-Rate (last

show packet-capture

```
show packet-capture
  controlpath-pcap [hex]
  datapath-pcap [hex]
```

Description

Displays packet capture status on the controller.

Parameter	Description
controlpath-pcap [hex]	Displays controlpath packets captured in the local-file system.
datapath-pcap [hex]	Displays datapath packets captured in the local-file system.

Example

The output of this command shows the packet capture configuration details.

```
(host)[mynode] #show packet-capture
Active Capture Destination
-----
Destination      IP          1.2.3.4
Active Capture (Controlpath)
-----
Interprocess     Disabled
Sysmsg           Disabled
TCP              Enabled     Ports: 2
UDP              Enabled     Ports: 5
Other            Enabled
Active Capture (Datapath)
-----
Wifi-Client      Enabled     Mac: 00:0b:86:6d:47:6c   Filter: Decrypted
Ipsec            Enabled     Peer: 10.1.1.1
(host) (config) #show packet-capture-defaults
Default Capture Destination
-----
Destination      Local-Filesystem
Default Capture (Controlpath)
-----
Interprocess     Disabled
Sysmsg           Disabled
TCP              Enabled     Ports: 80 8080
UDP              Enabled     Ports: All
Other            Disabled
Default Capture (Datapath)
-----
Wifi-Client      Enabled     Mac: 00:0b:86:6d:47:6c   Filter: Encrypted
Ipsec            Disabled

show pan statistics

show pan statistics

Description

This command shows PAN firewall interface statistics. Use this command to see the following interface statistics.

Example

The output of this command shows the show pan statistics configuration details.

```
(host)[node](config) #show pan statistics
Palo Alto Networks Interface Statistics Summary
-----
Login Reqts   Logout Reqts   Refresh Reqts
-----
0             0             0
Per-PAN server Statistics Summary
-----
PAN Server      User-ID Reqts   Sent   Skipped   Success   Failure   Last Error
-----
1.2.3.4:443    0             0     0         0         0         
```

Parameter	Description
Palo Alto Networks Interface Statistics Summary	
Login Reqts	Total number of login requests.
Logout Reqts	Total number of logout requests.
Refresh Reqts	Total number of refresh requests.
Per-PAN server Statistics Summary	
PAN Server	The PAN Server IP address.
User-ID Reqts	Total number of login, logout, and refresh requests.
Sent	Number of requests sent.
Skipped	Number of requests skipped.
Success	Number of requests successfully handled.
Failure	Number of requests that were not successfully received.

Parameter	Description
Last Error	The last failure error received.

Command History

show pan-options

show pan-options

Description

This command displays configured options to integrate a managed device with a Palo Alto Networks (PAN) firewall.

Issue this command to view Palo Alto Networks firewall integration settings for a managed device. Note that the PAN firewall integration feature can only be used on a managed device when used in conjunction with the managed device uplink VLAN manager feature, which must be enabled using the [uplink](#) command in the Mobility Conductor CLI.

Examples

The output of this command shows the show pan-options configuration details.

```
(host)[node]# show pan-options
Configure Palo Alto Networks options
-----
Parameter                                     Value
-----
Portal IP for Palo Alto Networks Global Protect portal 172.16.100.1 cert
cert_LSVPN_CA_7 username aruba123 password *****
```

The output of this command contains the following parameters:

Parameter	Description
Parameter	This column displays the Palo Alto Network (PAN) parameter.
Value	This column contains displays the following parameters for Palo Alto firewall integration feature: <ul style="list-style-type: none">portal-ip <ip-addr>: The IP address of the firewall management portalcert <cert-name>: Name of the self-signed or external certification authority (CA) certificate to sign the managed device and gateway server certificates

Related Commands

show papi-security

show papi-security

Description

This command shows a configured papi-security profile.

The `papi-security` command is used to enforce advanced security options and provides an enhanced level of security.

The **Parameter** column displays the PAPI Key and Enhanced security mode parameters. The **Value** column displays a Papi key value (encrypted) and indicates whether the Enhanced security mode is enabled or disabled.

```
(host)[mynode] #show papi-security

PAPI Security Profile
-----
Parameter                Value
-----
PAPI Key                  *****
Enhanced security mode    Enabled
```

Parameter	Description
PAPI Key	The key string. The key authenticates the messages between systems. 10-64 characters
Enhanced security mode	Indicates if the enhanced security mode is enabled or disabled. This mode causes the system to reject messages when an incorrect key is used. Disabled

show perf-test reports

```
show perf-test reports
  ap {ap-name <ap-name>}|{ip-addr <ip>}|{ip6-addr <ip6>}
  controller
```

Description

Use this command under the guidance of Aruba technical support to view the results of an Iperf throughput test launched from an AP or controller.

Tests launched in server mode do not generate reports. Only 130 Series, 220 Series, and AP-105 access points connected to a7200 Series controller support this feature.

Parameter	Description
ap	Display the results of an Iperf throughput test launched from an AP.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IPv4 address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
controller	Display the results of an Iperf throughput test launched from a controller.

Related Commands

show phonehome

```
show phonehome
  global
  history
  report-status
  stats
```

Description

Use this command to view current configuration settings and debugging statistics for the PhoneHome automatic reporting feature.

The automatic reporting feature, also known as *PhoneHome*, allows a controller to securely contact Aruba support servers over the Internet to report events such as hardware failures, software malfunctions, and other critical events. When the PhoneHome automatic reporting feature is enabled, the controller sends Aruba support weekly reports about the controller's configuration, licenses, software and hardware versions, and any software malfunctions via a secure email.

Parameter	Description
global	Show whether the PhoneHome service and auto-reporting is enabled or disabled, and display current HTTPS or SMTP settings for this feature.
history	Issue this command under the guidance of Aruba support troubleshoot PhoneHome automatic reporting.
report-status	Issue this command under the guidance of Aruba support troubleshoot PhoneHome automatic reporting.
stats	Include this parameter to show the number of weekly schedule or manual reports successfully sent to Activate or the SMTP server, the number of times the controller attempted to retry sending a report, and the number of reports that failed after one or more retry attempts, and

Example

The following command displays global phonehome settings:

```
(host)[mynode] #show phonehome global
PhoneHome information:
PhoneHome Service:      Disabled
PhoneHome Auto-Report:  Disabled
Local SMTP server:     192.0.2.10:25
SMTP From Email:       admin@example.com
```

Max Attachment Size: 10 MB
SMTP Authen User: John_Smith

              0          0
GE 0/0/1      0          0          0         0         0
              0          0
GE 0/0/2      0          0          0         0         0
              0          0
```

The output of this command includes the following parameters:

Parameter	Description
Port	Displays the physical port on the controller.
PacketIn	Indicates the total number of incoming packets to the port.
PacketOut	Indicates the total number of outgoing packets from the port.
BytesIn	Indicates the total number of incoming data (in bytes) to the port.
BytesOut	Indicates the total number of outgoing data (in bytes) from the port.
InputErrorBytes	Indicates input error bytes on the port.

Parameter	Description
OutputErrorBytes	Indicates the output error bytes on the port.
CRCErrors	Indicates the Cyclic Redundancy Check (CRC) errors on the port.
RxNoMbuf	Indicates the receive buffer allocated to handle traffic bursts.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show port status

show port status [<slot/module/port>]

Description

Displays the status of all ports on the controller.

Parameter	Description
<slot/module/port>]	Physical port in <slot>/<module>/<port> format.

Example

The output of this command shows the status of all ports in the controller.

```
(host)[mynode]# show port status
Port Status
-----
Slot-Port  PortType  AdminState  OperState  PoE  Trusted  SpanningTree
PortMode  Speed    Duplex    PortError
-----
- - - - -
0/0/0      GE        Enabled     Up          N/A  Yes      Disabled     Trunk
 10 Gbps   Full     -
0/0/1      GE        Disabled    Down        N/A  Yes      Disabled     Access
 Auto     Auto     -
```

The output of this command includes the following parameters:

Parameter	Description
Slot-Port	Physical port in <slot>/<module>/<port> format.
PortType	Displays the type of physical port. <ul style="list-style-type: none">▪ FE: Fast Ethernet▪ GE: Gigabit Ethernet▪ PC: Port Channel
AdminState	Indicates if the physical port is enabled or disabled.
OperState	Indicates if the current status of the physical port is up or down.
PoE	Indicates if the physical port is Power over Ethernet (PoE) enabled.

Parameter	Description
Trusted	Indicates if the physical port is trusted.
SpanningTree	Indicates the state of spanning tree.
PortMode	Indicates the port mode of the physical port.
Speed	Indicates the port speed.
Duplex	Indicates the direction of traffic.
PortError	Indicates is there is an error in the physical port.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show port trusted

show port trusted

Description

Displays the list of ports configured with trusted profiles.

Example

The output of this command shows the list of ports with trusted profile.

```
(host)[mynode]# show port trusted
FE 1/0
FE 1/1
FE 1/2
FE 1/3
GE 1/24
GE 1/25
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show port tunneled-node

show port tunneled-node

Description

This command shows the tunneled node ports.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The output of this command shows the tunneled node ports.

```
(host) [mynode] #show port tunneled-node
GE 0/0/4
GE 0/0/7
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show port xsec

```
show port xsec
```

Description

Displays the list of xSec enabled ports.

Example

The output of this command shows the list of xSec enabled ports.

```
(host)[mynode] #show port xsec

Xsec Ports
-----
Interface  xsec vlan  state
-----  -
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show port untrusted-vlan

show port untrusted-vlan

Description

This command shows untrusted port VLANs.

Example

The following command shows untrusted port VLANs,

```
(host)[mynode] #show port untrusted-vlan
Port Untrusted Vlan Table
-----
Name: Pc 0
Vlan(s): 1-4094
Name: Pc 1
Vlan(s): 1-4094
Name: Pc 2
Vlan(s): 1-4094
```

Related Commands

Command	Description

show priority-map

show priority-map

Description

Displays the list of priority maps on a interface.

Example

The output of this command shows the priority maps configured on all interfaces.

```
(host)[node] # show priority-map

Priority Map
-----
ID   Name      DSCP-TOS  DOT1P-COS
--   -
1    my-map    4-20,60   4-7
```

Related Commands

Command	Description
priority-map	This command configures the ToS and CoS values used to map traffic into high priority queues.
interface gigabitethernet	This command configures a GigabitEthernet interface.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show processes

show processes [sort-by {cpu | memory}]

Description

Displays the list of all system process running on the managed device. You can sort the list either by CPU intensive or memory intensive processes.

Parameter	Description
sort-by	Add a sort filter to the output
cpu	This will sort output based on CPU usage.
memory	This will sort output based on memory usage.

Example

The output of this command shows list of system processes sorted by CPU usage.

```
(host) [mynode] (config) # show processes

show profile

```
show profile
  profile-errors
  profile-hierarchy
  profile-list
```

Description

This command displays details of all profiles on the device.

Parameter	Description
profile-errors	Displays a list of profiles that are invalid.
profile-hierarchy	Displays the profile hierarchy.
profile-list	Displays the list of profiles of a given type.

Example

The following example shows the output of the `show profile-error` command:

```
Invalid Profiles
-----
Profile                               Error
-----
wlan virtual-ap "AOS-183773-WLAN"    Named VLAN "AOS-183773" does not exist.
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show profile-errors

```
show profile-errors
```

Description

Displays the list of invalid user-created profiles.

Example

The output of this command shows list of profiles that are invalid and also displays the error in those profiles. In this example, the VLAN 1000 that is mapped to a virtual-ap that does not exist.

```
(host)[node] #show profile-errors

Invalid Profiles
-----
Profile                Error
-----
wlan virtual-ap "test-vap"  VLAN 1000 does not exist
```

The following are the list of some profile errors:

Error	Description
Named VLAN [named_VLAN] is removed	These errors are displayed if a virtual AP profile is configured with a VLAN that does not exist.
Named VLAN [named_VLAN] is not mapped	
Named VLAN [named_VLAN] is invalid	
VLAN [x] does not exist	
Server group is invalid	This error is displayed if an AAA profile is configured an invalid server group.
User derivation rule is invalid	This error is displayed if a user role in an AAA profile is invalid.
User role is invalid	
controller country code is undefined	These errors are displayed, if your controller is not set to the correct country code or if the country code specified in a WLAN profile does not match the controller's country code.
Country [country_name] does not match controller country [country_name]	

Error	Description
Opmode requires WPA key	This message is displayed if a SSID profile is configured without a WPA key.
WARNING: if weptxkey = [x], wepkey[x] must be set in order to use static WEP	This message is displayed if a SSID profile is configured to use a static WEP and the WEP is not configured.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Config or Enable mode on Mobility Conductor.

show profile-hierarchy

show profile-hierarchy

Description

Displays the profile hierarchy template.

The output of this command shows how profiles relate to each other, and how some higher-level profiles reference other lower-level profiles. The output of this command will vary, depending upon controller configuration and licenses.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show profile-list

zigbee
```

Description

This command displays details of all profiles on the device.

Parameter	Description
<u>aaa</u>	Displays the list of AAA profiles.
<u>airgroupprofile</u>	Displays the list of configured AirGroup profiles.
<u>airslice-profile</u>	Displays the list of all Air Slice profiles.
<u>ap</u>	Displays the list of AP profiles.
<u>ap-group</u>	Displays the status of AP groups profiles in the controller.
<u>ap-name</u>	Displays the status of AP profiles in the controller.
<u>dump-collection-profile</u>	Displays the list of all dump collection profiles.

Parameter	Description
est	Displays the list of EST profiles.
ha	Displays the list of HA profiles.
ids	Displays the status of all IDS profiles in the controller.
iot	Displays the list of IOT profiles.
lc-cluster	Displays the list of classic controller cluster profiles.
license-pool-profile	Displays the list of license pool profiles.
mgmt-server	Displays all the management configuration profiles in the controller.
pan	Displays the list of all Palo Alto Networks servers profiles.
policy-domain	Displays the list of policy domain profiles.
rf	Displays the status of all radio profiles.
scheduler-profile	Displays the list of scheduler profiles.
sso	Displays the list of all SSO profiles.
time-range-profile	Displays the list of all time range profiles.
wlan	Displays the status of WLAN profiles on the controller.
zigbee	Displays the list of Zigbee profiles.

Example

The following example shows the output of the `aaa dns-query-interval` command:

```
20:4c:03:24:89:18 (config) # a
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Config mode on Mobility Conductor.

show profile-list aaa

```
show profile-list aaa [{alias-group [page | start]} | {authentication [captive-portal | dot1x | mac | stateful-ntlm | wispr]} | {authentication-server [ldap | radius | tacacs | windows]} | {profile} | {rfc-3576-server} | {server-group} | {xml-api}]
```

Description

Displays the list of AAA profiles.

Parameter	Description
alias-group	Lists all alias-groups.
page	Specify the number of items to display
start	Specify the first item to display
authentication	List of aaa authentication profiles.
captive-portal	Captive portal authentication profiles.
dot1x	802.1X authentication profiles.
mac	MAC authentication profiles.
stateful-kerberos	Stateful kerberos authentication profiles.
stateful-ntlm	Stateful-NTLM authentication profiles.
via	VIA authentication profile.
vpn	VPN authentication profiles.
wispr	WISPr authentication profiles.
authentication-server	List of aaa authentication servers
ldap	List of servers using LDAP for AAA authentication.
radius	List of servers using RADIUS for AAA authentication.
tacacs	List of servers using TACACS+ for AAA authentication.
windows	List of Windows servers used for AAA authentication.
profile	Displays the AAA profile details.
page	Specify the number of items to display

Parameter	Description
start	Specify the first item to display
radius modifier	Displays all RADIUS modifier profiles.
page	Specify the number of items to display
start	Specify the first item to display
rfc-3576-server	Displays IP address of RADIUS servers that use RFC 3576 specification to exchange authorization messages.
page	Specify the number of items to display
start	Specify the first item to display
server-group	List of server group used for RADIUS accounting.
page	Specify the number of items to display
start	Specify the first item to display
xml-api server	List of servers configured in an external XML API server.
page	Specify the number of items to display
start	Specify the first item to display

Example

The output of this command shows list of AAA profiles that use captive-portal authentication.

```
(host)[node] # show profile-list aaa authentication captive-portal

Captive Portal Authentication Profile List
-----
Name      References  Profile Status
----      -

show profile-list airgroupprofile

```
show profile-list airgroupprofile {cppm|domain|ipv6|page|service|start} [page | start]
```

Description

Displays the list of configured AirGroup profiles.

Parameter	Description
cppm	Displays all AirGroup ClearPass Policy Manager profiles.
domain	Displays all AirGroup domain profiles.
ipv6	Displays all AirGroup IPv6 profiles.
network	Displays all network profiles.
service	Displays all AirGroup service profiles.
page	Specify the number of items to display.
start	Specify the first item to display.

Example

The output of this command shows a list of AirGroup profiles.

```
(host)[node] (config) # show profile-list airgroupprofile
AirGroup Profile List
-----
Name      References  Profile Status
----      -
default  1
```

Related Commands

show profile-list airslice-profile

show profile-list airslice-profile [page | start]

Description

Displays the list of all Air Slice profiles.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
profile	Displays all Air Slice profiles.
page	Specify the number of items to display.
start	Specify the first item to display.

Example

The output of this command shows a list of Air Slice profiles.

```
(host) #show profile-list airslice-profile

airslice profile List
-----
Name      References  Profile Status
----      -
default  5
Total:1
```

Related Commands

Command	Description
airslice	This command configures an EST profile on the controller. This configuration is then pushed to the AP on successful enrollment.

Command History

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show profile-list ap

```
show profile-list ap [ am-filter-profile | authorization-profile | enet-link-profile | mesh-cluster-profile |  
  mesh-ht-ssid-profile | mesh-radio-profile | regulatory-domain-profile |  
  snmp-profile | snmp-user-profile | system-profile | wired-ap-profile ]
```

Description

Displays the list of AP profiles.

Parameter	Description
am-filter-profile	Display a list of all AM filters.
authorization-profile	Display a list of AP Authorization profiles.
enet-link-profile	Display a list of AP Ethernet link profiles.
lldp	Display Link-layer Discovery Protocol.
mesh-accesslist-profile	Display a list of all mesh accesslist profiles.
mesh-cluster-profile	Display a list of mesh cluster profiles used by mesh nodes.
mesh-ht-ssid-profile	Display a list of mesh high-throughput SSID profiles used by mesh nodes.
mesh-radio-profile	Display a list of mesh radio profiles used by mesh nodes.
multizone-profile	Display a list of all AP MultiZone profile.
provisioning-profile	Display a list of all provisioning profiles.
provisioning-rule	Display a list of all ap provisioning rules.
regulatory-domain-profile	Display a list of AP regulatory profiles.
snmp-profile	Display a list of SNMP profiles.
snmp-user-profile	Display a list of SNMPv3 user profiles.
system-profile	Display a list of AP system profiles.
usb-acl-prof	Display a list of all AP USB ACL profiles.
usb-profile	Display a list of all AP USB profiles.
wifi-uplink-profile	Display a list of all WiFi uplink profiles.

Parameter	Description
wired-ap-profile	Display a list of wired AP profiles.
wired-port-profile	Display a list of all AP wired port profiles.

Example

The output of this command shows list of profiles that are invalid and also displays the error in those profiles.

```
(host)[mynode] # show profile-list aaa authentication captive-portal
Captive Portal Authentication Profile List
-----
Name      References  Profile Status
----      -
default  1
```

show profile-list est

show profile-list est profile [page | start]

Description

Displays the list of EST profiles.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
profile	Displays all EST profiles.
page	Specify the number of items to display.
start	Specify the first item to display.

Example

The output of this command shows a list of EST profiles.

```
(host)[node] (config) # #show profile-list est profile

EST Profile List
-----
Name      References  Profile Status
----      -
default  0
Total:1
```

Related Commands

show profile-list iot

```
show profile-list iot radio-profile [page <number>] [start <number>] | transport-profile [page <number>] [start <number>]
```

Description

This command is used to display the list of IOT profiles.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
radio-profile	Displays IoT radio profiles.
transport-profile	Displays IoT transport profiles.
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The output of this command shows a list of IoT radio profiles,

```
(host)[mynode] #show profile-list iot radio-profile
IoT Radio Profile List
-----
Name  References  Profile Status
----  -
Total:0
```

Related Commands

Command	Description

show profile-list ha

```
show profile-list ha
  group-profile [page | start]
```

Description

Displays the list of HA profiles.

Parameter	Description
group-profile	Lists all HA group information.
page	Specify the number of items to display
start	Specify the first item to display

Example

The output of this command shows list of HA group profile information.

```
(host)[node] # show profile-list ha group-profile
HA group information List
-----
Name  Profile Status
----  -
Total:0
```

Related Commands

Command	Description
ha	This command configures the High Availability:Fast Failover feature by assigning a managed device or standby controller to a high-availability group, and defining the deployment role for each controller.

Command History

show profile-list ids

```
show profile-list ids [ap-classification-rule | dos-profile | general-profile |
impersonation-profile |
profile | rap-wml-server-profile | rap-wml-table-profile | rate-thresholds-
profile | signature-matching-profile |
signature-profile | unauthorized-device-profile ]
```

Description

Displays the status of all IDS profiles in the controller.

Parameter	Description
ap-classification-rule	Show all IDS AP classification rule profiles.
dos-profile	Display a list of IDS DoS profiles.
general-profile	Display a list of IDS general profiles.
impersonation-profile	Display a list of IDS impersonation profiles.
profile	Display a list of IDS profiles.
rap-wml-server-profile	Show all IDS RAP WML server profiles.
rap-wml-table-profile	Show all IDS RAP WML table profiles.
rate-thresholds-profile	Display a list of IDS rate threshold profiles.
signature-matching-profile	Display a list of IDS signature-matching profiles.
signature-profile	Display a list of IDS signature profiles.
unauthorized-device-profile	Display a list of IDS unauthorized device profiles.

Example

The output of this command shows a list of all IDS DoS profiles.

```
(host)[node] # show profile-list ids dos-profile
IDS Denial Of Service Profile List
-----
Name                References  Profile Status
----                -
default             1
ids-dos-disabled    1          Predefined
ids-dos-high-setting 1          Predefined
ids-dos-low-setting  1          Predefined
```

```
ids-dos-medium-setting 1          Predefined
Total:5
```

show profile-list license-pool-profile

show profile-list license-pool-profile [page | start]

Description

Displays the list of license pool profiles.

Parameter	Description
page	Specify the number of items to display.
start	Specify the first item to display.

Example

The output of this command shows a list of all licensing pools.

```
(host)[node] (config) #show profile-list license-pool-profile
License pool profile List
-----
Name           References  Profile Status
----           -

show profile-list policy-domain

```
show profile-list policy domain
  group-profile
    page <page>
    start <start>
```

Description

Displays the list of policy domain profiles.

Parameter	Description
group-profile	Displays all policy domain profiles.
page <page>	Specify the number of items to display.
start <start>	Specify the index of first item to display.

Example

The output of this command shows the list of policy domain profiles.

```
(host) # show profile-list policy-domain group-profile

Policy Domain Profile List
-----
Name  Profile Status
----  -
Total:0
```

Related Commands

Command	Description

All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show profile-list rf

```
show profile-list rf [ am-scan-profile | arm-profile | dot11-60GHz-radio-profile |  
dot11-6GHz-radio-profile | dot11a-radio-profile | dot11a-secondary-radio-  
profile |  
dot11g-radio-profile | event-thresholds-profile | ht-radio-profile |  
optimization-profile | spectrum-profile ]
```

Description

Displays the status of all radio profiles.

Parameter	Description
am-scan-profile	Display AM scanning profiles.
arm-profile	Display details of Adaptive Radio Management (ARM) Profiles.
dot11-60GHz-radio-profile	Display details of AP radio settings for the 60GHz frequency band.
dot11-6GHz-radio-profile	Display details of AP radio settings for the 6GHz frequency band.
dot11a-radio-profile	Display details of AP radio settings for the 5GHz frequency band, including the ARM profile and the high-throughput (802.11n) radio profile.
dot11a-secondary-radio-profile	Display details of secondary AP radio settings for the 5GHz frequency band, including the ARM profile and the high-throughput (802.11n) radio profile.
dot11g-radio-profile	Display details of AP radio settings for the 2.4 GHz frequency band, including the ARM profile and the high-throughput (802.11n) radio profile.
event-thresholds-profile	Display details of events thresholds profile.
ht-radio-profile	Display details of high-throughput AP radio settings
optimization-profile	Display details of the RF optimization profile
spectrum-profile	Display details of the spectrum profile

Example

The output of this command shows status of ARM profile.

```
(host) # show profile-list rf arm-profile

Adaptive Radio Management (ARM) profile List
-----
Name      References  Profile Status
-----
default   2
Total:1
```

  hotspot
  ht-ssid-profile
  mu-edca-parameters-profile
  rrm-ie-profile
  ssid-profile
  traffic-management-profile
  tsm-req-profile
  virtual-ap
  wmm-traffic-management-profile
```

Description

Displays the status of WLAN profiles on the controller.

Parameter	Description
6ghz-rrm-ie-profile	Show a list of all RRM IE profiles for 6GHz
anyspot-profile	Shows a list of all anyspot profiles
bcn-rpt-req-profile	Shows a list of all Beacon Report Request profiles
client-wlan-profile	Shows a list of all client WLAN profiles
dot11r-profile	Shows a list of all 802.11r profiles
dot11k-profile	Show a list of all 802.11K profiles
edca-parameters-profile	Show a list of all enhanced distributed channel access (EDCA) profile for APs or for clients (stations)
he-ssid-profile	Show a list of all high-efficiency SSID profiles
hotspot	Hotspot/Passpoint configuration settings
advertisement-profile	Shows a list of all Advertisement profile
angp-3gpp-nwk-profile	Shows a list of all ANQP 3GPP Cellular Network profiles

Parameter	Description
anqp-domain-name-profile	Shows a list of all ANQP Domain Name profiles
anqp-ip-addr-avail-profile	Shows a list of all ANQP IP Address Availability profiles
anqp-nai-realm-profile	Shows a list of all ANQP NAI Realm profiles
anqp-nwk-auth-profile	Shows a list of all ANQP Network Authentication profiles
anqp-roam-cons-profile	Shows a list of all ANQP Roaming Consortium profiles
anqp-venue-name-profile	Shows a list of all ANQP Venue Name profiles
h2qp-conn-capability-profile	Shows a list of all H2QP Connection Capability profiles
h2qp-op-cl-profile	Shows a list of all H2QP Operating Class Indication profiles
h2qp-operator-friendly-profile	Shows a list of all H2QP Operator Friendly Name profiles
h2qp-wan-metrics-profile	Shows a list of all H2QP WAN Metrics profiles
hs2-profile	Shows a list of all Hotspot 2.0 profiles
ht-ssid-profile	Show a list of all high-throughput SSID profiles
mu-edca-parameters-profile	Show a list of all MU EDCA parameters profiles
rrm-ie-profile	Shows a list of all Radio Resource Management Information Element (RRM IE) profiles
ssid-profile	Show a list of all SSID profiles.
traffic-management-profile	Show a list of all traffic management profiles
tsm-req-profile	Show a list of all Transmit Stream/Category Measurement (TSM) request profiles
virtual-ap	Show a list of all the virtual AP profiles
wmm-traffic-management-profile	Show a list of all WMM traffic management profiles

Example

The output of this command shows that the controller has a single ARM profile, "default".

```
(host)[mynode] # show profile-list wlan anysot-profile

Anysot profile List
-----
```

Name	References	Profile Status
----	-----	-----

Total:0

show provisioning

```
show provisioning
  rule info
  params
  ap-list
```

Description

This command displays the AP provisioning details that are described in the following table:

Parameter	Description
<rule-info>	Displays detailed information about the AP auto-provisioning rules.
<params>	Displays the list of parameters and the values used to provision the APs.
<ap-list>	Displays the list of all APs that are in queue to be provisioned by the admin.

Example

The following example shows the output of the `show-provisioning` command:

```
provisioning-ap-list    The APs that are being provisioned
provisioning-params    Show AP provisioning parameters
provisioning-rule-info  AP auto provisioning rule
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

show provisioning-rule-info

```
show provisioning-rule-info [record <rule-name>|summary]
```

Description

This command displays detailed information about the AP auto-provisioning rules.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
record <rule-name>	Display information about the MAC address of the AP that the auto-provisioning rule is applied to, along with the provisioning time, LMS IP of the AP, and auto-provisioning state of the AP.
summary	Display information about the auto-provision rule of each AP in ascending order of the rule-priority, the hit times of that rule, as well as the success and failure count of the rules.

Examples

The following example displays the summary of the auto-provisioning rules.

```
(host) [mm] #show provisioning-rule-info summary

Auto provision Rule Info
-----
Rule Name  Priority  Hit times  Success count
-----
ap324      1         0          0
ip36       3         0          0
network    5         0          0
ip46       7         0          0
The following example displays information on each auto-provisioning rule and
the associated AP.
(host) [mm] #show provisioning-rule-info record ap324
Auto provision Rule Info
-----
Rule Name  Priority  Hit times  Success count
-----
ap324      1         1          1

Auto provision Rule Record
-----
```

```

AP MAC          Provision Time      LMS
-----          -
40:e3:d6:cd:82:34  2018-07-01 13:55:06  10.65.46.203

```

The output of this command includes the following information:

Parameter	Description
Rule Name	Indicates the name of the auto-provisioning rule that is applied to the AP.
Priority	Indicates the priority level of the auto-provisioning rule. The rules are listed in ascending order of the priority level.
Hit times	Indicates the hit times of the auto-provisioning rule.
Success count	Indicates the success count of the auto-provisioning rule.
AP MAC	Indicates the MAC address of the AP that the auto-provisioning rule is applied to.
Provision Time	Indicates the date and time when the auto-provisioning rule is applied to the AP.
LMS	Indicates the LMS IP of the AP that the auto-provisioning rule is applied to.

Related Commands

show rap-wml

```
show rap-wml [cache <server-name> | servers | wired-mac <bssid>]
```

Description

Displays the name and attributes of a MySQL database or a MySQL server.

Parameter	Description
cache <server-name>	Displays the cache of all look-ups for a database server.
servers	Displays the database server state.
wired-mac <bssid>	Displays the wired MAC discovered on traffic through the AP.

Example

The output of this command shows status of all database servers.

```
(host) [mynode] #show rap-wml servers

WML DB Servers
-----
name ip type user password db-name cache ageout(sec) in-service
-----
WML DB Tables
-----
server db table column timestamp-column lookup-time(sec) delimiter

show references aaa alias-group

```
show references aaa
  alias-group <ag_name>
  [page <page>] [start <start>]
```

Description

Shows AAA profile references to an alias group.

Parameter	Description
alias-group <ag_name>	Shows the references to an Alias group.
page <page>	Include this optional parameter to limit output of this command to the specified number of items.
start <start>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

Use this command to show the references to an alias group.

```
(host)[mynode] #show references aaa alias-group alias1
```

Related Commands

Command	Description
aaa alias-group	Configures an AAA alias with set of VLAN derivation rules that could speed up user rule derivation processing for deployments with a very large number of user derivation rules.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

show references aaa authentication

```
show references aaa authentication
  captive-portal {default | <profile-name>}
  dot1x {default | <profile-name>}
  mac {default | <profile-name>}
  mgmt
  stateful-dot1x
  stateful-kerberos {default | <profile-name>}
  stateful-ntlm {default | <profile-name>}
  via
    auth-profile {default | <profile-name>}
    connection-profile {default | <profile-name>}
    global-config
    web-auth <default>
  vpn {default | <profile-name>}
  wired
  wispr {default | <profile-name>}
  [page <page>] [start <start>]
```

Description

This command shows AAA profile references.

Parameter	Description	Default
captive-portal <profile-name>	Shows the number of references to a captive-portal profile.	default
dot1x <profile-name>	Shows the number of references to a 802.1X authentication profile.	default
mac <profile-name>	Shows the number of references to a MAC authentication profile.	default
mgmt	Shows the number of references to a management authentication profile.	
stateful-dot1x <profile-name>	Shows the number of references to the stateful 802.1X authentication profile.	default
stateful-kerberos <profile-name>	Shows references to a Stateful Kerberos authentication profile.	default

Parameter	Description	Default
<code>stateful-ntlm <profile-name></code>	Shows the number of references to the specified stateful NTLM authentication profile.	default
<code>via</code>	Shows the number of references to VIA.	
<code>auth-profile <profile-name>}</code>	Shows references to a VIA authentication profile.	default
<code>connection-profile <profile-name></code>	Shows references to a VIA connection profile.	default
<code>global-config</code>	Shows references to the VIA global configuration.	
<code>web-auth <default></code>	Shows references to a VIA web authentication.	default
<code>vpn <profile-name></code>	Shows the number of references to VPN authentication.	default
<code>wired</code>	Shows the number of references to wired authentication.	
<code>wispr <profile-name></code>	Shows the number of references to the specified WISPr authentication profile.	default
<code>page <page></code>	Include this optional parameter to limit output of this command to the specified number of items.	
<code>start <start></code>	Include this optional parameter to start displaying the output of this command at the specified index number.	

Example

Use this command to show where a specified AAA profile has been applied. The output of the example shown here indicates that the aaa profile **default-dot1x** contains a single reference to the 802.1X authentication profile **default**.

```
(host)[mynode] #show references aaa authentication dot1x default
```

```

References to 802.1X Authentication Profile "default"
-----
Referrer                                     Count
-----
aaa profile "default-dot1x" authentication-dot1x  1
Total References:1

```

Related Commands

Command	Description

show references aaa authentication-server

```
show references aaa authentication-server
  ldap <ldap_server_name>
  radius <rad_server_name>
  tacacs <tacacs_server_name>
  windows <windows_server_name>
  [page <page>] [start <start>]
```

Description

This command displays information about AAA authentication servers.

Parameter	Description
ldap <ldap-server-name>	Show the number of server groups that include references to the specified LDAP server.
radius <rad_server_name>	Show the number of server groups that include references to the specified RADIUS server.
tacacs <tacacs_server_name>	Show the number of server groups that include references to the specified TACACS server.
windows <windows_server_name>	Show the number of server groups that include references to the specified Windows server.
page <page>	Include this parameter to limit output of this command to the specified number of items.
start <start>	Include this parameter to start displaying the output of this command at the specified index number.

Example

Issue this command to show the AAA server groups that include references to the specified server. The example below shows that two server groups, **default** and **rad**, each include a single reference to the RADIUS server **rad01**.

```
(host)[mynode] #show references aaa authentication-server radius rad01

References to RADIUS Server "rad01"
-----
Referrer                                Count
-----                                -
aaa server-group "default" server_group  1
aaa server-group "rad" server_group      1
Total References:2
```

Related Commands

Command	Description
aaa authentication-server ldap	Configures an LDAP server.
aaa authentication-server radius	Configures a RADIUS server.
aaa authentication-server tacacs	Configures a TACACS+ server.
aaa authentication-server windows	Configures a windows server for stateful-NTLM authentication.

Command History

show references aaa password-policy

```
show references aaa password-policy mgmt
```

Description

This command shows the password policy for locally configured management users.

Parameter	Description
mgmt	Shows references to the Management Password Policy.

Example

Execute the following command to show the password policy for locally configured management users.

```
(host)[mynode] #show references aaa password-policy mgmt
```

Related Commands

Command	Description
aaa password-policy mgmt	Defines a policy for creating management user passwords.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references aaa profile

show references aaa profile <profile-name>

Description

This command shows references to an AAA Profile.

Parameter	Description
profile <profile-name>	Name of an AAA profile for which you want to view references.

Example

Issue this command to show the wlan virtual AP profiles that include references to the specified AAA profile. The example below shows that seven different virtual AP profiles include a single reference to the AAA profile **default**.

```
(host)[mynode] #References to AAA Profile "default"
-----
Referrer                                     Count
-----
wlan virtual-ap "1.0.0_corporateHQ-wpa2" aaa-profile 1
wlan virtual-ap "110.0_corporateHQ-wpa2" aaa-profile 1
wlan virtual-ap "default" aaa-profile 1
wlan virtual-ap "corporateHQ-vocera" aaa-profile 1
wlan virtual-ap "corporateHQ-voip-wpa2" aaa-profile 1
wlan virtual-ap "Test123" aaa-profile 1
wlan virtual-ap "branch12" aaa-profile 1
Total References:7
```

Related Commands

Command	Description
aaa profile	This command configures the authentication for a WLAN.

Command History

show references aaa radius

```
show references aaa
  radius modifier <rad_modifier_name>
  [page <page>] [start <start>]
```

Description

This command shows information about the configuration profiles that reference a specific RADIUS modifier profile.

Parameter	Description
<code>radius modifier <rad_modifier_name></code>	Shows references to a RADIUS modifier profile.
<code>page <page></code>	Include this parameter to limit output of this command to the specified number of items.
<code>start <start></code>	Include this parameter to start displaying the output of this command at the specified index number

Example

The following is an example to execute the `show references aaa radius modifier` command:

```
(host) [mynode] #show references aaa radius modifier RADIUSProfile1
```

Related Commands

Command	Description
aaa radius modifier	Configures the RADIUS modifier profile to customize the attributes that are included, excluded, and modified in the RADIUS request before it is sent to the authentication server.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references aaa radius-attributes

```
show references aaa
  radius-attributes <node-path>
```

Description

This command shows information about the configuration profiles that reference a specific RADIUS modifier profile.

Parameter	Description
radius-attributes	Displays references to RADIUS attributes.
<node-path>	Displays the path of the configuration node.

Usage Guidelines

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following is an example to execute the `show references aaa radius-attributes` command:

```
(host) [mynode] #show references aaa radius-attributes HW-Cluster-1
```

Related Commands

Command	Description
aaa radius-attributes	Configures the RADIUS attributes to statically configure values to be included in RADIUS Access- Requests and Accounting-Requests.

Command History

show references aaa rfc-3576-server

```
show references aaa
  rfc-3576-server <server_ip>
  [page <page>] [start <start>]
```

Description

This command shows information about the configuration profiles that reference a specific RFC 3576 server.

Parameter	Description
rfc-3576-server <server_ip>	IP address of an RFC-3576 server.
page <page>	Include this parameter to limit output of this command to the specified number of items.
start <start>	Include this parameter to start displaying the output of this command at the specified index number

Example

This first example shows that the **default** AAA profile and the AirGroup ClearPass Policy Manager-server AAA profile reference an RFC 3567 Server with the IP address 10.1.1.41.

```
(host)[mynode] #show references aaa rfc-3576-server 10.1.1.41
References to RFC 3576 Server "10.1.1.41"
-----
Referrer                                     Count
-----
aaa profile "default" rfc-3576-server       1
airgroup cppm-server aaa rfc-3576-server    1
Total References:2
```

show references aaa server-group

```
show references aaa server-group
  <sg_name>
  [page <page>][start <start>]
```

Description

This command shows references to a server group.

Parameter	Description
<sg_name>	Name of the server group for which you want to show references
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <start>	Include this parameter to start displaying the output of this command at the specified index number.

Example

Issue this command to display a list of AAA profiles that include references to the specified server group.

```
(host)[mynode] #show references aaa server-group default

References to Server Group "default"
-----
Referrer                                     Count
-----

show references airgroupprofile

```
show references airgroupprofile
  activate
  cppm <airgroup-cppm-name>
  domain <airgroup-domain-name>
  ipv6 <ipv6-profile-name>
  network <network-profile-name>
  service <service-name>
  [page <page>] [start <start>]
```

Description

This command shows the references to the AirGroup profile information.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
activate	Displays references to the active AirGroup profile.
cppm <airgroup-cppm-name>	Displays references to the AirGroup ClearPass Policy Manager profile.
domain <airgroup-domain-name>	Displays references to an AirGroup domain profile.
ipv6 <ipv6-profile-name>	Displays references to the AirGroup IPv6 profile.
network <network-profile-name>	Displays references to the network profile.
service <service-name>	Displays references to the AirGroup service profile. By default, the following services are available: <ul style="list-style-type: none">■ default-airplay■ default-airprint■ default-allowall■ default-amazontv■ default-dial■ default-dlna-media■ default-dlna-print■ default-googlecast■ default-itunes■ default-remotemgmt■ default-sharing
<profile-name>	Configures an AirGroup profile.
page <page>	Include this optional parameter to limit output of this command to the specified number of items.

Parameter	Description
start <start>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

Use this command to show the AirGroup domain profiles.

```
(host)[mynode] ##show references airgroupprofile cppm test
```

Related Commands

Command	Description
airgroupprofile	Configures AirGroup profile settings.

Command History

Release	Modification
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references airmatch

```
show references airmatch
  profile
  [page <page>] [start <start>]
```

Description

The `show references profile` command displays profile references. No other profiles reference the AirMatch profile, so the output of this always displays a reference count of 0.

Parameter	Description
<code>profile</code>	Shows references to the AirMatch profile
<code>page <page></code>	Include this parameter to limit output of the <code>show references</code> command to the specified number of items.
<code>start <start></code>	Include this parameter to start displaying the output of the <code>show references</code> command at the specified index number.

Example

The `show references <profile>` command displays a list of profiles that include references to the selected profile. No other profiles reference the AirMatch profile, so this table always displays a reference count of 0.

```
(host) [mynode] #show references airmatch profile
References to AirMatch
-----
Referrer  Count
-----  ----
Total References:0
```

Related Commands

Command	Description
airmatch profile	Configures the AirMatch profile.

show references airslice-profile

```
show references airslice-profile <profile name>
    [page <page>] [start <start>]
```

Description

This command displays references to an airslice profile.

Parameter	Description
<profile name>	Specify profile name.
page <page>	Include this optional parameter to limit output of this command to the specified number of items.
start <start>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

```
(host)[mynode] #show references airslice-profile default

References to airslice profile "default"
-----
Referrer                                     Count
-----
ap-group "$(touch /flash/config/proof1)" airslice-profile 1
ap-group "default" airslice-profile 1
ap-group "NoAuthApGroup" airslice-profile 1
Total References:3
```

Related Commands

  general-profile
  lldp
    med-network-policy-profile
      {default | <profile-name>}
    profile
  mesh-accesslist-profile {default | <profile-name>}
  mesh-cluster-profile {default | <profile-name>}
  mesh-ht-ssid-profile {default | <profile-name>}
  mesh-radio-profile {default | <profile-name>}
  multizone-profile {default | <profile-name>}
  provisioning-profile {default | <profile-name>}
  provisioning-rule {default | <profile-name>}
  provisioning-rules
  regulatory-domain-profile {default | <profile-name>}
  spectrum local-overridead
  system-profile {default | <profile-name>}
  usb-acl-prof {default | <profile-name>}
  usb-profile {default | <profile-name>}
  wifi-uplink-profile {default | <profile-name>}
  wired-ap-profile {default | <profile-name>}
  wired-port-profile
  [page <page>] [start <start>]
```

Description

This command shows the number of references to a specific AP profile.

Parameter	Description	Default
am-filter-profile <profile-name>	Shows references to an AM filter.	default
authorization-profile <profile-name>	Shows references to an AP Authorization profile.	default
deploy-profile	Show references to the AP deploy-profile.	
enet-link-profile <profile-name>	Shows AP groups that include a references to this Ethernet link profile.	default

Parameter	Description	Default
general-profile	Shows references to the ap general-profile.	
lldp	Shows references to the Link-layer Discovery Protocol profile.	
mesh-accesslist-profile <profile-name>	Shows references to the mesh accesslist profile.	default
med-network-policy-profile <profile-name>	Shows references to LLDP-MED Network Policy profile of an AP.	
profile	Shows references to an AP LLDP profile.	
mesh-cluster-profile <profile-name>	Shows AP groups that include a references to this mesh cluster profile.	default
mesh-ht-ssid-profile <profile-name>	Shows AP groups that include a references to this mesh high-throughput SSID profile.	default
mesh-radio-profile <profile-name>	Shows AP groups that include a references to this mesh radio profile.	default
multizone <profile-name>	Shows references to an AP MultiZone profile.	default
provisioning-profile <profile-name>	Shows references to a Provisioning profile.	default
provisioning-rule	Shows references to an ap provisioning rule.	default
provisioning-rules	Shows references to the ap provisioning rules.	
regulatory-domain-profile <profile-name>	Shows AP groups that include a references to this regulatory domain profile.	default
spectrum local-override	Shows references to the Spectrum Local Override Profile.	
system-profile <profile-name>	Shows AP groups that include a references to this system profile.	default

Parameter	Description	Default
usb-acl-prof <profile-name>	Shows references to an AP USB ACL profile.	
usb-profile <profile-name>	Shows references to an AP USB profile.	
wifi-uplink-profile <profile-name>	Shows references to a WiFi uplink profile.	
wired-ap-profile <profile-name>	Shows AP groups that include a references to this wired AP profile.	default
wired-port-profile <profile-name>	Shows references to an AP wired port profile	default
page <page>	Include this optional parameter to limit output of this command to the specified number of items.	
start <start>	Include this optional parameter to start displaying the output of this command at the specified index number.	

Example

The example below shows that 10 different AP groups include links to the AP Ethernet link profile **Default**. These 10 AP groups reference the **Default** Ethernet link profile for both their Ethernet 0 and Ethernet 1 interfaces, for a total of 20 references altogether.

```
(host)[mynode] #show references ap enet-link-profile default

References to AP Ethernet Link profile "default"
-----
Referrer                                     Count
-----
ap-group "10.0.0" enet0-profile             1
ap-group "10.0.0" enet1-profile             1
ap-group "corp" enet0-profile               1
ap-group "corp" enet1-profile               1
ap-group "Corp_AM_Ch1" enet0-profile        1
ap-group "Corp_AM_Ch1" enet1-profile        1
ap-group "Corp_AM_Ch6" enet0-profile        1
ap-group "Corp_AM_Ch6" enet1-profile        1
ap-group "corpTest" enet0-profile           1
ap-group "corpTest" enet1-profile           1
ap-group "default" enet0-profile            1
```

```

ap-group "default" enet1-profile 1
ap-group "India_Local" enet0-profile 1
ap-group "India_Local" enet1-profile 1
ap-group "ops" enet0-profile 1
ap-group "ops" enet1-profile 1
ap-group "voip-test" enet0-profile 1
ap-group "voip-test" enet1-profile 1
ap-group "voip-test-nokia" enet0-profile 1
ap-group "voip-test-nokia" enet1-profile 1
Total References:20

```

Related Commands

Command	Description
ap am-filter-profile	Configures an AM filter.
ap authorization-profile	Defines a temporary configuration profile for remote APs that are not yet authorized on the network.
ap deploy-profile	Configures an AP deployment profile.
ap enet-link-profile	Configures an AP Ethernet link profile.
ap general-profile	Configures the general profile of an AP.
ap lldp profile	Defines an LLDP profile that specifies the type-length-value (TLV) elements to be sent in LLDP PDUs.
ap lldp med-network-policy-profile	Defines an LLDP MED network policy profile that defines DSCP values and L2 priority levels for a voice or video application.
ap mesh-cluster-profile	Configures a mesh cluster profile used by mesh nodes.
ap mesh-ht-ssid-profile	Configures a mesh high-throughput SSID profile used by mesh nodes.
ap mesh-radio-profile	Configures a mesh radio profile used by mesh nodes.
ap multizone-profile	Attaches the profile to ap-group or ap-name.
ap provisioning-profile	Defines a provisioning profile for an AP or group of APs.
ap regulatory-domain-profile	Configures an AP regulatory domain profile.
ap spectrum local-override	Converts an AP or AM into a spectrum monitor by adding it to the spectrum local-override list.
ap system-profile	Configures an AP system profile.

Command	Description
ap wired-ap-profile	Configures a wired AP profile.
ap wired-port-profile	Configures a wired port profile.

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>ap deploy-profile</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

show references ap-lacp-striping-ip

```
show references
  ap-lacp-striping-ip
  [page <page>] [start <start>]
```

Description

This command shows the references to the AP LACP LMS map information.

Parameter	Description
ap-lacp-striping-ip	Shows references to AP LACP LMS map information.

Example

The following is an example for execution of the `show references ap-lacp-striping-ip` command:

```
(host) [mynode] #show references ap-lacp-striping-ip
```

Related Commands

Command	Description
ap-lacp-striping-ip	Configures the AP LACP LMS map information.

show references ap-name

```
show references
  ap-name <profile-name>
  [page <page>] [start <start>]
```

Description

This command shows the number of references to a specific AP-group profile.

Parameter	Description
ap-name <profile-name>	Shows references to an AP name profile.

Example

The following is an example for execution of the `show references ap-name` command:

```
(host) [mynode] #show references ap-name ap228
```

Related Commands

Command	Description
ap-name	Configures a specific AP.

show references ble

```
show references ble
  service-profile <profile-name>
```

Description

This command displays references to a ble profile.

Parameter	Description
<code>service-profile <profile name></code>	Specify ble profile name.
<code>page <page></code>	Include this optional parameter to limit output of this command to the specified number of items.
<code>start <start></code>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

```
(host)[mynode] #show references ble service-profile wli-test

References to Ble Service Profile "wli-test"
-----
Referrer  Count
-----  ----
Total References:0
```

Related Commands

Command	Description

show references bw-contract

```
show references
  bw-contract <name> [revert_cmd]
  [page <page>] [start <start>]
```

Description

This command shows the number of references to bandwidth contract.

Parameter	Description
<code>bw-contract <name></code>	Shows references to bandwidth contract. Specify the bandwidth contract name.
<code>[revert_cmd]</code>	List of no commands to change the value.

Example

The following is an example for execution of the `show references bw-contract` command:

```
(host) [mynode] #show references bw-contract bwcontract1
```

Related Commands

Command	Description
aaa bandwidth-contract	This command configures a bandwidth contract.
cp-bandwidth-contract	This command configures a bandwidth contract traffic rate, which can then be associated with a whitelist/allowlist session ACL.
firewall cp-bandwidth-contract	This command configures bandwidth contract traffic rate limits, in packets per second, to prevent denial of service attacks.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of whitelist have been replaced with allowlist .
ArubaOS 8.0.0.0	Command introduced.

show references control-plane-security

```
show references
  control-plane-security
  [page <page>] [start <start>]
```

Description

This command shows the number of references to bandwidth contract.

Parameter	Description
control-plane-security	Shows references to the Control Plane Security Profile.

Example

The following is an example for execution of the `show references control-plane-security` command:

```
(host) [mynode] #show references control-plane-security
```

Related Commands

Command	Description
control-plane-security	Configures the control plane security profile by identifying APs to receive security certificates.

All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references dump-collection-profile

```
show references dump-collection-profile {default | <profile-name>}  
[page <number>][start <number>]
```

Description

This command shows references to a dump collection profile.

Parameter	Description
{default <profile-name>}	Specify the profile for collecting core dump when an AP process crashes.
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following is an example of the command that shows references to a dump collection profile,

```
(host)[mynode] #show references dump-collection-profile default  
  
References to Dump collection profile "default"  
-----  
Referrer                                     Count  
-----  
ap system-profile "default" dump-collection-profile 1  
ap system-profile "NoAuthApSystem" dump-collection-profile 1  
Total References:2
```

show references est profile

```
show references
  est profile {default | <profile-name>}
  [page <page>] [start <start>]
```

Description

This command shows the number of references to bandwidth contract.

Parameter	Description
est profile <profile-name>	Show references to an EST Profile.

Example

The following is an example for execution of the `show references est profile` command:

```
(host) [mynode] #show references est profile default
```

Related Commands

Related Command	Description
est	This command configures an EST profile on the controller. This configuration is then pushed to the AP on successful enrollment.

show references ids

```
show references ids
  ap-classification-rule <rule-name>
  ap-rule-matching
  dos-profile {default | <profile-name>}
  general-profile {default | <profile-name>}
  impersonation-profile {default | <profile-name>}
  management-profile
  profile {default | <profile-name>}
  rap-wml-server-profile <server-name>
  rap-wml-table-profile <table-name>
  rate-thresholds-profile {default | <profile-name>}
  signature-matching-profile {default | <profile-name>}
  signature-profile <profile-name>
  unauthorized-device-profile {default | <profile-name>}
  wms-general-profile
  wms-local-system-profile
```

Description

This command displays IDS profile references.

Parameter	Description	Default
ap-classification-rule <rule-name>	Shows references to an IDS AP classification rule profile.	
ap-rule-matching	Shows references to the IDS Active AP Rules Profile.	
dos-profile <profile-name>	Shows references to an IDS Denial of Service (DoS) profile.	default
general-profile <profile-name>	Shows references to an IDS general profile.	default
impersonation-profile <profile-name>	Shows references to an IDS impersonation profile.	default
management-profile	Shows references to the IDS WMS management profile.	
profile <profile-name>	Shows references to an IDS profile.	default

Parameter	Description	Default
rap-wml-server-profile <server-name>	Shows references to an IDS remote AP WML server profile.	
rap-wml-table-profile <table-name>	Shows references to an IDS remote AP WML table profile	
rate-thresholds-profile <profile-name>	Shows references to an IDS rate thresholds profile.	default
signature-matching-profile <profile-name>	Shows references to an IDS signature matching profile.	default
signature-profile <profile-name>	Shows references to an IDS signature profile.	default
unauthorized-device-profile <profile-name>	Shows references to an unauthorized device profile.	default
wms-general-profile	Shows references to the IDS WMS general profile.	
wms-local-system-profile	Shows references to the IDS WMS local system profile.	

Example

Execute the following command to display a list of references for the default IDS profile.

```
(host) [mynode] #show references ids profile default
References to IDS Profile "default"
-----
Referrer                                Count
-----
ap-group "default" ids-profile          1
ap-group "NoAuthApGroup" ids-profile    1
Total References:2
```

Related Commands

Command	Description
<u>ids ap-classification-rule</u>	Configures the IDS AP classification rule profile.
<u>ids ap-rule-matching</u>	Configures the IDS active AP rules profile by enabling an AP classification rule.
<u>ids dos-profile</u>	Configures traffic anomalies for denial of service (DoS) attacks.
<u>ids general-profile</u>	Configures an IDS general profile.
<u>ids impersonation-profile</u>	Configures anomalies for impersonation attacks.
<u>ids management-profile</u>	Configures the IDS WMS management profile.
<u>ids profile</u>	Defines a set of IDS profiles.
<u>ids rate-thresholds-profile</u>	Configures an IDS rate thresholds profile.
<u>ids signature-matching-profile</u>	Configures an IDS signature matching profile.
<u>ids signature-profile</u>	Configures signatures for wireless intrusion detection.
<u>ids unauthorized-device-profile</u>	Configures detection of unauthorized devices, as well as rogue AP detection and containment.
<u>ids wms-general-profile</u>	configures the IDS WLAN management system (WMS) general profile.

show references ifmap cppm

```
show references
  ifmap cppm
  [page <page>] [start <start>]
```

Description

This command displays the ClearPass Policy Manager IF-MAP references.

Parameter	Description
ifmap cppm	Shows references to the ClearPass Policy Manager IF-MAP profile.
page <page>	Include this parameter to limit output of this command to the specified number of items.
start <start>	Include this parameter to start displaying the output of this command at the specified index number.

Example

Execute this command to display a list of references for the ClearPass Policy Manager IF-MAP profile.

```
(host) [mynode] #show references ifmap cppm
References to CPPM IF-MAP Profile
-----
Referrer  Count
-----  -----
Total References:0
```

Related Commands

Command	Description
ifmap	Sends HTTP User Agent Strings and mDNS broadcast information to ClearPass Policy Manager so that it can make more accurate decisions about what types of devices are connecting to the network.

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references lc-cluster

```
show references lc-cluster group-profile <profile-name> {page<page> start<start>}
```

Description

Displays controller Cluster Profile references.

Parameter	Description
group-profile <profile-anme>	Name of the lc-cluster group profile for which you want to show references.
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

```
(host) [MDC] #show references lc-cluster group-profile wli-dev-v4  
  
References to Classic Controller Cluster Profile "wli-dev-v4"  
-----  
Referrer   Count  
-----  
Total References:0
```

Related Commands

Command	Description
lc-cluster group-profile	This command is used to configure the cluster group profile in the Mobility Conductor.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Managed device.

show references lcd-menu

```
show references lcd-menu {page<number> start<number>}
```

Description

This command shows references to lcd-menu.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output. This command can be executed only on **/md subtree**. This command is not supported on Mobility Controller - Virtual Appliance platform.

Related Commands

Related Command	Description
lcd-menu	This command allows you to enable or disable the LCD menu either completely or for specific operations.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Managed device.

show references license-pool-profile

```
show references
  license-pool-profile
  [page <page>] [start <start>]
```

Description

This command displays references to a License pool profile.

Parameter	Description
<code>license-pool-profile</code>	Shows references to the license-pool profile.
<code>page <page></code>	Include this parameter to limit output of this command to the specified number of items.
<code>start <start></code>	Include this parameter to start displaying the output of this command at the specified index number.

Example

Execute this command to display a list of references for the license-pool profile.

```
(host)[node] #show references license-pool-profile
```

Related Commands

Related Command	Description
license-pool-profile	Creates a local licensing pool and allocate licenses for that licensing pool.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references license-pool-profile-root

```
show references
  license-pool-profile-root
  [page <page>] [start <start>]
```

Description

This command displays references to a License root (/) pool profile.

Parameter	Description
license-pool-profile-root	Shows references to the license root (/) pool profile.
page <page>	Include this parameter to limit output of this command to the specified number of items.
start <start>	Include this parameter to start displaying the output of this command at the specified index number.

Example

Execute this command to display a list of references for the license-pool profile.

```
(host)[node] #show references license-pool-profile-root

References to License root(/) pool profile
-----
Referrer  Count
-----  ----
Total References:0
```

Related Commands

Related Command	Description
license-pool-profile	Creates a local licensing pool and allocate licenses for that licensing pool.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references mgmt-server profile

```
show references mgmt-server profile <profile_name>
```

Description

Shows the management server configuration profiles.

Parameter	Description
mgmt-server profile	Specifies the management profile name.
page <number>	Include this optional parameter to limit output of this command to the specified number of items.
start <number>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

```
(host)[mynode] #show references mgmt-server profile default
References to Mgmt Config profile "default"
-----
Referrer  Count
-----  -----
Total References:0
```

Related Commands

Related Command	Description
mgmt-server	This command configures the management server profile.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

show references openflow-controller

```
show references openflow-controller {page<number> start<number>}
```

Description

This command shows references to openflow controller.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following command show references to openflow controller,

```
(host)[mm] #show references openflow-controller
References to Openflow-controller
-----
Referrer  Count
-----  -----
Total References:0
```

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Related Command	Description
openflow-controller	This command configures OpenFlow controller on the Mobility Conductor.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references openflow-profile

```
show references openflow-profile {page<number> start<number>}
```

Description

This command shows references to openflow-profile.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following command show references to openflow-profile,

```
(host)[mm] #show references openflow-profile
References to Openflow-profile
-----
Referrer  Count
-----  -----
Total References:0
```

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Related Command	Description
openflow-profile	This command configures openflow profile on the managed device.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references pan

```
show references pan {active-profile [page<number> start<number>]} | {profile <default|profile-name> [page<number> start<number>]}
```

Description

This command shows references to Palo Alto Networks configuration.

Parameter	Description
active-profile	Shows references to the Palo Alto Networks Active Profile.
profile <default profile-name>	Shows references to the Palo Alto Networks Servers Profile.
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following command show references to Palo Alto Networks configuration,

```
(host)[mm] #show references pan active-profile
References to Palo Alto Networks Active Profile
-----
Referrer  Count
-----  -----
Total References:0
```

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Related Command	Description
pan-active-profile	This command makes a Palo Alto Network profile active from a set of profiles.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references pan-options

```
show references pan-options [page<number> start<number>]
```

Description

This command shows references to configure Palo Alto Networks options.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output. This command can be executed only on **/md subtree**.

Example

```
(host) [MDC] ##show references pan-options
References to Configure Palo Alto Networks options
-----
Referrer  Count
-----  -----
Total References:0
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Managed Device.

show references papi-security

```
show references papi-security [page <number>] [start <number>]
```

Description

Show references to a PAPI security profile.

Parameter	Description
page <number>	Include this optional parameter to limit output of this command to the specified number of items.
start <number>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

```
(host) [node]#show references papi-security

References to PAPI Security Profile
-----
Referrer  Count
-----  ----
Total References:0
```

Related Commands

Related Command	Description
papi-security	The papi-security command enforces advanced security options and provides an enhanced level of security. It allows to enable or disable the PAPI Enhanced Security configuration and to configure a new security key if required.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

show references rf

```
show references rf
  am-scan-profile <profile-name>
  arm-profile <profile-name>
  arm-rf-domain-profile <profile-name>
  dot11-60GHz-radio-profile <profile-name>
  dot11-6GHz-radio-profile <profile-name>
  dot11a-radio-profile <profile-name>
  dot11a-secondary-radio-profile
  dot11g-radio-profile <profile-name>
  event-thresholds-profile <profile-name>
  ht-radio-profile <profile-name>
  optimization-profile <profile-name>
  spectrum-profile <profile-name>
```

Description

Show RF profile references.

Parameter	Description
am-scan-profile	Show references to an AM Scanning profile
arm-profile	Show references to an Adaptive Radio Management (ARM) profile.
arm-rf-domain-profile	Show references to the ARM RF domain profile.
dot11-60GHz-radio-profile	Show references to a 60 GHz radio profile
dot11-6GHz-radio-profile	Show references to a 6 GHz radio profile.
dot11a-radio-profile	Show references to a 802.11a radio profile.
dot11a-secondary-radio-profile	Show references to a secondary 802.11a radio profile.
dot11g-radio-profile	Show references to a 802.11g radio profile.
event-thresholds-prof	Show references to an RF Event Thresholds profile.
ht-radio-profile	Show references to a High-throughput radio profile.
optimization-profile	Show references to an RF Optimization profile.
spectrum-profile	Show references to a Spectrum profile.

Example

```
(host)[mm] #show references rf spectrum-profile default-a

References to Spectrum profile "default-a"
-----
Referrer                                     Count
-----
rf dot11a-radio-profile "default" spectrum-profile      1
rf dot11a-radio-profile "rp-maintain-a" spectrum-profile 1
rf dot11a-radio-profile "rp-monitor-a" spectrum-profile 1
rf dot11a-radio-profile "rp-scan-a" spectrum-profile     1
Total References:4
```

Related Commands

Related Command	Description
rf arm-profile	This command configures the Adaptive Radio Management (ARM) profile.

Command History

Release Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show references scheduler-profile

```
show references scheduler-profile {default | <map-name> } [page<number>]
start<number>]
```

Description

This command shows references to a scheduler profile.

Parameter	Description
default <map-name>	Shows references to the default profile or to a specific profile.
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following command shows references to a scheduler profile,

```
(host)[mm] #show references scheduler-profile default
References to scheduler profile "default"
-----
Referrer  Count
-----  -----
Total References:0
```

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Related Command	Description
scheduler-profile	Define a schedule profile that associates priorities to four uplink queues.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references sdwan-profile

```
show references sdwan-profile [page<number> start<number>]
```

Description

This command shows references of the SD-WAN profile.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following command shows references of the SD-WAN profile,

```
(host)[mm] #show references sdwan-profile
References to sdwan-profile
-----
Referrer  Count
-----  -----
Total References:0
```

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Command	Description
sdwan-profile	This command enables or disables an SD-WAN profile.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references sso idp-profile

```
show references sso idp-profile <sso_prof_name> [page<number> start<number>]
```

Description

This command shows references to an SSO profile.

Parameter	Description
<code>idp-profile <sso_prof_name></code>	Name of the SSO profile.
<code>page <number></code>	Include this parameter to limit output of this command to the specified number of items.
<code>start <number></code>	Include this parameter to start displaying the output of this command at the specified index number.

The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Related Commands

Command	Description
sso-idp profile	This command configures an SSO Identity Provider profile.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references time-range-profile

```
show references time-range-profile <profile-name> [page<number> start<number>]
```

Description

This command shows references to a time range profile.

Parameter	Description
<profile-name>	Name of the profile.
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Command	Description
time-range-profile	This command configures a time-range-profile.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references traceoptions

```
show references traceoptions [page<number> start<number>]
```

Description

This command shows references to traceoptions.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

Command	Description
traceoptions	This command configures the traceoptions to monitor and log traffic flows.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor and Managed Device.

show references ucc

```
show references ucc
  custom-sip
  facetime
  h323
  ich
  jabber
  noe
  rtpa-config
  sccp
  session-idle-timeout
  sip
  skype4b
  teams
  vocera
  webrtc
  wificalling
    page <page>
    start <start>
```

Description

This command displays the UCC ALG references to a profile.

Parameter	Description
custom-sip	Show references to the custom-sip ALG configuration.
facetime	Show references to the Apple FaceTime ALG configuration.
h323	Show references to the H.323 ALG configuration.
ich	Show references to the Intelligent Call Handling configuration.
jabber	Show references to the Cisco Jabber ALG configuration.
noe	Show references to the Alcatel-Lucent New Office Environment (NOE) ALG configuration.
rtpa-config	Show references to the Real-Time Analysis configuration.
sccp	Show references to the Cisco SCCP ALG configuration.
session-idle-timeout	Show references to the UCC Session Idle Timeout configuration.
sip	Show references to the SIP ALG configuration.
skype4b	Show references to the Microsoft Skype for Business ALG configuration.

Parameter	Description
teams	Show references to the Microsoft Teams ALG configuration.
vocera	Show references to the Vocera ALG configuration.
webrtc	Show references to the WebRTC ALG configuration
wificalling	Show references to the Wi-Fi Calling configuration.
page <number>	Include this optional parameter to limit output of this command to the specified number of items.
start <number>	Include this optional parameter to start displaying the output of this command at the specified index number.

Example

```
(host)[mynode]#show references u skype4b

References to Skype4B ALG Configuration
-----
Referrer  Count
-----  -----
Total References:0
```

Related Commands

Related Command	Description
UCC	This command configures the various UCC Application Layer Gateways (ALGs).

Command History

Command	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show references upgrade-profile

```
show references upgrade-profile {page<page> start<start>}
```

Description

Displays the upgrade profile references.

Parameter	Description
<code>upgrade-profile</code>	Shows references to the upgrade profile.
<code>page <number></code>	Include this parameter to limit output of this command to the specified number of items.
<code>start <number></code>	Include this parameter to start displaying the output of this command at the specified index number.

Example

Issue this command to display a list of references for the upgrade profile.

```
(host)[mynode]#show references upgrade-profile
References to Upgrade Profile
-----
Referrer  Count
-----  ----
Total References:0
```

Related Commands

Related Command	Description
upgrade-profile	This command is used to configure the upgrade profile.

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system	Config mode on Mobility Conductor

show references user-role

```
show references user-role <role_name>
```

Description

Show access rights for user role.

Parameter	Description
<role_name>	The role name assigned to a user.

Example

```
(host)[mynode] #show references user-role guest

References to User Role "guest"
-----
aaa profile "airwave-office-ssid" mac-default-role
aaa profile "amigopod-guest" mac-default-role
aaa profile "corp1344-voip" mac-default-role
aaa profile "default" mac-default-role
aaa profile "default-airwave-office" mac-default-role
aaa profile "default-corp1344" mac-default-role
aaa profile "default-corp1344-no-okc" mac-default-role
aaa profile "default-corp1344-okc" mac-default-role
aaa profile "default-dot1x" mac-default-role
aaa profile "default-dot1x-psk" mac-default-role
aaa profile "default-dot1x-psk" dot1x-default-role
aaa profile "default-India" mac-default-role
aaa profile "default-india-hotel" mac-default-role
```

Related Commands

Related Command	Description

show references websocket clearpass

```
show references websocket clearpass [page<number> start<number>]
```

Description

This command shows references to the ClearPass WebSocket profile.

Parameter	Description
page <number>	Include this parameter to limit output of this command to the specified number of items.
start <number>	Include this parameter to start displaying the output of this command at the specified index number.

Example

The following command shows references to the valid equipment OUI profile,

```
(host)[mm] #show references websocket clearpass
References to ClearPass WebSocket Profile
-----
Referrer  Count
-----  -----
Total References:0
```

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Related Commands

  sae-profile
  ssid-profile <profile-name>
  traffic-management-pr <profile-name>
  tsm-req-profile
  virtual-ap <profile-name>
  wmm-traffic-management
```

Description

Show information about the different configuration profiles that reference a specific WLAN profile.

Parameter	Description
6ghz-rrm-ie-profile	Shows references to an RRM IE profile for 6 GHz.
anyspot-profile	Shows references to an Anyspot profile.
bcn-rpt-req-profile	Shows references to a Beacon Report Request profile.

Parameter	Description
client-wlan-profile	Shows references for the Client WLAN profile.
dot11k-profile <profile-name>	Shows references to a 802.11k profile.
dot11r-profile <profile-name>	Shows references to a 802.11r profile.
edca-parameters-profile <profile-name>	Shows references to an EDCA parameters profile.
he-ssid-profile	Shows references to a high-efficiency SSID profile.
hotspot	Shows references to one of the following hotspot profile types: <ul style="list-style-type: none"> ■ advertisement-profile ■ anqp-3gpp-nwk-profile ■ anqp-domain-name-profile ■ anqp-ip-addr-avail-profile ■ anqp-nai-realm-profile ■ anqp-nwk-auth-profile ■ anqp-roam-cons-profile ■ anqp-venue-name-profile ■ h2qp-conn-capability-profile ■ h2qp-op-cl-profile ■ h2qp-operator-friendly-name-profile ■ h2qp-wan-metrics-profile ■ hs2-profile
ht-ssid-profile <profile-name>	Shows references to a high-throughput SSID profile.
mu-edca-parameters-profile	Shows references to an MU EDCA parameters profile.
rrm-ie-profile	Shows references to an RRM IE profile.
sae-profile	Shows references to the WPA3 SAE configuration.
ssid-profile <profile-name>	Shows references to an SSID management profile.
traffic-management-profile <profile-name>	Shows references to a traffic management profile.
virtual-ap <profile-name>	Shows references to a virtual AP profile.
tsm-req-profile	Show references to a TSM Report Request profile.
wmm-traffic-management	Shows references to a WMM Traffic management profile.

Example

The following example shows that two different WLAN hotspot 2.0 profiles reference the **default** WLAN hotspot advertisement profile.

```
(host) [mynode] #show references wlan hotspot advertisement-profile default

References to Advertisement Profile "default"
-----
Referrer                                     Count
-----
wlan hotspot hs2-profile "deploytest" advertisement-profile 1
wlan hotspot hs2-profile "default" advertisement-profile    1

Total References:2
```

show references zigbee

```
show references zigbee
  service-profile <profile-name>
  socket-device-profile <profile-name>
  socket-inbound-profile <profile-name>
  socket-outbound-profile <profile-name>
```

Description

Show info socket-inbound-profile rmatoin about specific zigbee profile.

Parameter	Description
<code>service-profile <profile-name></code>	Displays references to specified ZigBee service profile.
<code>socket-device-profile <profile-name></code>	Displays references to specified Zigbee socket device profile.
<code>socket-inbound-profile <profile-name></code>	Displays references to specified Zigbee socket inbound profile.
<code>socket-outbound-profile <profile-name></code>	Displays references to specified Zigbee socket outbound profile.

Example

```

show rf am-scan-profile

```
show rf am-scan-profile [<profile-name>]
```

Description

Display the AM scanning profile list. Optionally display parameter and values of a specified Air Monitor profile.

Parameter	Description
<profile-name>	Name of this instance of the profile.

Enter the basic show command to view a list of profiles, the number of profiles and the profile status. For example:

```
(host) [mynode]#show rf am-scan-profile

AM Scanning profile List
-----
Name       References  Profile Status
-----
default    9
north      0

Total:2
```

Example

In the example above, there are two profile names; default and north. The Reference column indicates the number of references to this profile name. The Profile Status column is blank unless the profile is predefined.

Optionally, you can enter a profile name to view the parameters for that profile. For example:

```
(host) [mynode]#show rf am-scan-profile default

AM Scanning profile "default"
-----
Parameter                               Value
-----
Scan Mode                                all-reg-domain
Dwell time: Active channels                500
Dwell time: Regulatory Domain channels    250
Dwell time: non-Regulatory Domain channels 200
Dwell time: Rare channels                  100
```

The explanation of the display output is described in the table below.

Parameter	Description
Scan-mode	The scanning mode for the radio
all-reg-domain	Scan channels in all regulatory domain
rare	Scan all channels (all regulatory domains and rare channels)
reg-domain	Scan channels in the APs regulatory domain
Dwell time: Active channels	Dwell time (in ms) for channels where there is wireless activity
Dwell time: Regulatory Domain channels	Dwell time (in ms) for AP's Regulatory domain channels
Dwell time: non-Regulatory Domain channels	Dwell time (in ms) for channels not in the APs regulatory domain
Dwell time: Rare channels	Dwell time (in ms) for rare channels

show rf arm-profile

```
show rf arm-profile [<profile>]
```

Description

Show an ARM profile.

Parameter	Description
<profile>	Name of an ARM profile.

Issue this command without the <profile> parameter to display the entire ARM profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Examples

The example below shows that the controller has five configured ARM profiles. The **References** column lists the number of other profiles with references to the ARM profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[node] # show rf arm-profile
Adaptive Radio Management (ARM) profile List
-----
Name                References  Profile Status
----                -
airwave             2
default             4
default-AP85        2
no-scanning         1
Wireless-rf-profile                1

Total:5.

The output of this command includes the following parameters:

Parameter	Description
Assignment	Displays the current ARM channel/power assignment mode.
Allowed bands for 40MHz channels	Shows if 40 MHz mode of operation is allowed on the 5 GHz (802.11a) or 2.4 GHz (802.11b/g) frequency band only, on all frequency bands, or on neither frequency band.
Client Aware	Shows if the client aware feature is enabled or disabled. When enabled, the AP does not change channels when there are active clients.
Max Tx Power	The highest transmit power levels for the AP, from 0-30 dBm in 3 dBm increments. Higher power level settings may be constrained by local regulatory requirements and AP capabilities. In the event that an AP is configured for a Max Tx Power setting it cannot support, this value will be reduced to the highest supported power setting.
Min Tx Power	The lowest transmit power levels for the AP, from 0-30 dBm, in 3 dBm increments. Note that power settings will not change if the Assignment option is set to disabled or maintain.
Multi Band Scan	If enabled, single-radio APs will try to scan across bands for rogue AP detection.
Rogue AP Aware	If enabled, Aruba APs may change channels to contain off-channel rogue APs with active clients. This security features allows APs to change channels even if the Client Aware setting is disabled. This setting is disabled by default, and should only be enabled in high-security environments where security requirements are allowed to consume higher levels of network resources. You may prefer to receive Rogue AP alerts via SNMP traps or syslog events.
Scan Interval	If Scanning is enabled, the Scan Interval defines how often the AP will leave its current channel to scan other channels in the band. Off-channel scanning can impact client performance. Typically, the shorter the scan interval, the higher the impact on performance. If you are deploying a large number of new APs on the network, you may want to lower the Scan Interval to help those APs find their optimal settings more quickly. Raise the Scan Interval back to its default setting after the APs are functioning as desired.
Aggressive Scanning	When the aggressive scanning feature is enabled, an AP radio with no clients will scan channels every second.

Parameter	Description
Active Scan	If enabled, the AP initiates active scanning via probe request. This option elicits more information from nearby APs, but also creates additional management traffic on the network. Active Scan is disabled by default, and should not be enabled except under the direct supervision of Aruba Support.
Scanning	Shows if the AP has enabled or disabled AP scanning of other channels.
VoIP Aware Scan	Shows if Aruba's VoIP Intelligent Call Handling prevents any single AP from becoming congested with voice calls. If Intelligent Call Handling is enabled, you should also enable VoIP Aware Scan in the ARM profile, so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call.
Power Save Aware Scan	When enabled, the AP will not scan if Power Save is active.
Video Aware Scan	If Video Aware Scan is enabled in the ARM profile, the AP will not attempt to scan a different channel if one of its clients has an active video session.
Ideal Coverage Index	The coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be.
Acceptable Coverage Index	The minimal coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be.
Free Channel Index	The difference in the interference index between the new channel and current channel must exceed this value for the AP to move to a new channel. The higher this value, the lower the chance an AP will move to the new channel.
Backoff Time	Time, in seconds, an AP backs off after requesting a new channel or power level.
Error Rate Threshold	The percentage of errors in the channel that triggers a channel change.
Error Rate Wait Time	Time, in seconds, that the error rate has to maintain or surpass the error rate threshold before it triggers a channel change.
Channel Quality Aware Arm	Shows if ARM changes are based upon an internally calculated channel quality metric. When this feature is disabled, ARM initiates channel changes based on thresholds defined in this profile, and chooses the channel based on the calculated interference index value.

Parameter	Description
Channel Quality Threshold	Displays the channel quality percentage below which ARM initiates a channel change.
Channel Quality Wait Time	If channel quality is below the specified channel quality threshold for this wait time period, ARM initiates a channel change.
Minimum Scan Time	Time, in seconds, that a channel must be scanned before it is considered for assignment.
Load aware Scan Threshold	The traffic throughput level an AP must reach before it stops scanning, in bytes/second. A value of 0 to disables this feature.
Mode Aware Arm	If enabled, ARM will turn APs into AMs if it detects higher coverage levels than necessary. This helps avoid higher levels of interference on the WLAN. Although this setting is disabled by default, you may want to enable this feature if your APs are deployed in close proximity (e.g. less than 60 feet apart).
Scan Mode	<p>This parameter defines the scan mode for the AP.</p> <ul style="list-style-type: none"> ■ all-reg-domain: The AP scans channels within all regulatory domains. This is the default setting. ■ reg-domain: Limit the AP scans to just the regulatory domain for that AP.
Client Match	<p>The client match feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is enabled by default</p>
Client Match report interval (sec)	This interval defines how often an AP sends an updated client probe report to the controller. Each client probe report contains a list of MAC addresses for clients that have been active in the last two minutes, and the AP radio SNR values seen by those clients.
Client Match Unsteerable Client Ageout Interval	The client entries in an unsteerable client list remain in effect for the interval defined by this parameter before they age out.

Parameter	Description
Client Match Unsteerable Client Ageout	When client match and the client match unsteerable client ageout feature are enabled, the controller periodically sends APs that are not a desired AP match for a client in a list of unsteerable clients. These lists contain a list of MAC addresses for up to 128 clients that should not be steered to that AP.
Client Match Sticky Client Check Interval (sec)	Frequency at which the AP checks for client's received SNR values. If the SNR value drops below the threshold defined by the cm-sticky-snr parameter for three consecutive check intervals, that client may be moved to a different AP.
Client Match Sticky Client Check SNR (dB)	If the client's received signal strength indicator (RSSI) is above this signal-to-noise ratio (SNR) threshold, that client will be allowed to stay associated to its current AP. If the client's received signal strength is below this threshold, it may be moved to a different AP.
Client Match SNR threshold(dB)	A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the AP radio is stronger than its current radio by the dB level defined by the cm-sticky-snr-thresh parameter, and the candidate radio also has a minimum signal level defined by the cm-sticky-min-signal parameter.
Client Match Sticky Min Signal	A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the candidate AP radio is at or higher than the minimum signal level defined by this parameter <i>and</i> the candidate radio has a higher signal strength than the radio to which the client is currently associated. (The required improvement in signal strength can be defined using the cm-sticky-snr-delta command.)
Client Match Restriction timeout (sec)	When a client is steered from one AP to a more desirable AP, the steer timeout feature helps facilitate the move by defining the amount of time that any APs to which the client should NOT associate will not respond to the AP.
Client Match Load Balancing threshold (%)	When the client match feature is enabled, clients may be steered from a highly utilized channel on an AP to a channel with fewer clients. If a channel on an AP radio has this percentage fewer clients than another channel supported by the client, the client match feature may move clients from the busier channel to the channel with fewer clients.
Client Match VBR Stale Entry Age (sec)	The controller can maintains client match data for the maximum number of supported clients for that controller platform, showing the detected SNR values for up to 16 candidate APs per client. This table is periodically updated as APs send client probe reports to the controller. This parameter defines the amount of time that the controller should retain client match data from each client probe report.

Parameter	Description
Client Match Max Steer Failures	The controller keeps track of the number of times the client match feature failed to steer a client to a different radio, and the reason that each steer attempt was triggered. If the client match feature attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as unsteerable for that specific trigger. This parameter defines the maximum allowed number of client match steering fails with the same trigger before the client is marked as unsteerable for that trigger.
Client Match Load Balancing Client Threshold	If an AP radio has fewer clients than the client match load balancing threshold defined by this parameter, the AP will not participate in load balancing.
Client Match Load Balancing SNR Threshold (dB)	Clients must detect a SNR from an underutilized AP radio at or above this threshold before the client match feature considers load balancing a client to that radio.
Dynamic Bandwidth Switch	ARM dynamic 80MHz/40MHz bandwidth switch when 80MHz assignment is enabled.
Dynamic Bandwidth Switch Wait Time (sec)	Minimum time in seconds during which dynamic bandwidth switch indicators have to be true to trigger a 80MHz to 40MHz bandwidth change.
Dynamic Bandwidth Switch Triggering Indicator CCA ibss Threshold (%)	Dynamic Bandwidth Switch wait time window starts when load aware scan rejects increases and CCA ibss is below the threshold.
Dynamic Bandwidth Switch Triggering Indicator Beacon Failed Threshold	Dynamic Bandwidth Switch beacon failed indicator is true if beacon failed num is no less than this threshold during the wait time window.
Dynamic Bandwidth Switch Triggering Indicator CCA intf Threshold (%)	Dynamic Bandwidth Switch CCA intf indicator is true if CCA intf is no less than this threshold during the wait time window.
Dynamic Bandwidth Switch Clear Time (min)	Dynamic Bandwidth Switch back to 80MHz channel after the clear time in minutes if currently there is no high volume of traffic.

The output of this command includes the following parameters:

Parameter	Description
Radio enable	Shows if the AP has enabled or disabled transmissions on this radio band.
Mode	Access Point operating mode. Available options are: <ul style="list-style-type: none"> ■ am-mode: Air Monitor mode ■ ap-mode: Access Point mode ■ apm-mode: Access Point Monitor mode ■ sensor-mode: RFprotect sensor mode
High throughput enable (radio)	Shows if high-throughput (802.11n) is enabled on the radio. A high-throughput profile manages 40 Mhz tolerance settings, and controls whether or not APs using this profile will advertise intolerance of 40 MHz operation. (This option is disabled by default, allowing 40 MHz operation.)

Parameter	Description
	A high-throughput profile also determines whether an AP radio using the profile will stop using the 40 MHz channels surrounding APs or stations advertise 40 Mhz intolerance. This option is enabled by default.
Very high throughput enable (radio)	Enable or disable support for Very High Throughput (802.11ac) on the radio. This option is enabled by default.
Channel	Channel number for the AP 802.11a, 802.11n, or 802.11ac physical layer.
Transmit EIRP	Maximum transmit power (EIRP) in dBm from 0 to 51 in .5 dBm increments. Further limited by regulatory domain constraints and AP capabilities.
Non-Wi-Fi Interference Immunity	<p>Sets a value for 802.11 Interference Immunity. The default setting for this parameter is level 2. When performance drops due to interference from non-802.11 interferers (such as DECT or Bluetooth devices), the level can be increased up to level 5 for improved performance. However, increasing the level makes the AP slightly “deaf” to its surroundings, causing the AP to lose a small amount of range.</p> <p>The levels for this parameter are:</p> <ul style="list-style-type: none"> ▪ Level-0: no ANI adaptation. ▪ Level-1: noise immunity only. ▪ Level-2: noise and spur immunity. This is the default setting ▪ Level-3: level 2 and weak OFDM immunity. ▪ Level-4: level 3 and FIR immunity.
Spur Immunity	<p>Displays the spur immunity value for 802.11a radio.</p> <p>NOTE: This parameter is applicable for 130 Series access points only. The controller ignores this parameter if configured for non-130 Series access points.</p>
Enable CSA	Shows if CSAs are enabled or disabled. CSAs, as defined by IEEE 802.11h, enable an AP to announce that it is switching to a new channel before it begins transmitting on that channel. This allows clients that support CSA to transition to the new channel with minimal downtime.
CSA Count	Number of channel switch announcements that must be sent prior to switching to a new channel. The default CSA count is 4 announcements.
Spectrum Monitoring	If enabled, the AP operates as a hybrid AP that can simultaneously serve clients and monitor a single channel for spectrum analysis data.

Parameter	Description
Spectrum Monitoring Profile	The spectrum monitoring profile referenced by APs using this 802.11a radio profile. For details, see rf spectrum-profile on page 1254
Advertise 802.11d and 802.11h Capabilities	If enabled, the radio advertises its 802.11d (Country Information) and 802.11h (Transmit Power Control) capabilities.
Spectrum load balancing	<p>The Spectrum load balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p>
Spectrum load balancing mode	SLB Mode allows control over how to balance clients. Channel-based load-balancing balances clients across channels. Radio-based load-balancing distributes clients across radios on the same band, independent of channels.
Spectrum load balancing mode update interval	This parameter specifies how often spectrum load balancing calculations are made (in seconds). The default value is 30 seconds.
Spectrum load balancing threshold	If the spectrum load balancing feature is enabled, this parameter controls the percentage difference between number of clients on a channel channel that triggers load balancing. The default value is 20%, meaning that spectrum load balancing is activated when there are 20% more clients on one channel than on another channel used by the AP radio.
Spectrum load balancing domain	<p>Define a spectrum load balancing domain to manually create RF neighborhoods.</p> <p>Use this option to create RF neighborhood information for networks that have disabled ARM scanning and channel assignment.</p> <ul style="list-style-type: none"> ▪ If spectrum load balancing is enabled in a 802.11a radio profile but the spectrum load balancing domain is <i>not</i> defined, ArubaOS uses ARM to calculate RF neighborhoods. ▪ If spectrum load balancing is enabled in a 802.11a radio profile and a spectrum load balancing domain <i>is/also</i> defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize

Parameter	Description
	RF neighborhoods defined by ARM.
Beacon Period	Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.
Beacon Regulate	If enabled, this option introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air. This option is disabled by default.
Advertised Regulatory Max EIRP	Shows if the radio is configured to work around a known issue on Cisco 7921G telephones by capping for a radio's maximum EIRP. When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons. The supported value is 1-31 dBm.
ARM/WIDS Override	If enabled, this option disables ARM and Wireless IDS functions and slightly increases packet processing performance. If a radio is configured to operate in Air Monitor mode, then the ARM/WIDS override functions are always enabled, regardless of whether or not this check box is selected.
Reduce Cell Size (Rx Sensitivity)	The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.
Energy Detect Threshold Offset	This parameter can modify the energy detect threshold used by the radio in making transmit decisions. The energy detect threshold is a negative value, and the value specified for this parameter (1-12) is the offset from the base value of -59 dBm. For example a value of 1 = -60 dBm, and a value of 10: = -69 dBm. A value of 0 indicates the AP is using the default energy detect threshold for this radio. (This value may vary by AP model)
Frame Bursting Mode	The frame bursting mode of the AP. <ul style="list-style-type: none"> ■ Dynamic: Frame bursting is enabled only when one active client is connected to the AP, and frame bursting is disabled when there is more than one active client. ■ OFF: Frame bursting mode is always disabled. ■ ON: Frame bursting mode is always enabled.

Parameter	Description
Management Frame Throttle Interval	Averaging interval for rate limiting mgmt frames from this radio, in seconds. A management frame throttle interval of 0 seconds disables rate limiting.
Management Frame Throttle Limit	Maximum number of management frames that can come in from this radio in each throttle interval.
Maximum Distance	Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km..
RX Sensitivity Threshold	If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (-dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength. For example, if the RX sensitivity threshold was set to -65 dBm, the AP would ignore signals with a strength from -1 dBm to -64 dBm. If the value is set to zero, the feature will automatically determine an appropriate threshold.
RX Sensitivity Tuning Based Channel Reuse	Shows if the channel reuse feature's current operating mode, static, dynamic or disable. <ul style="list-style-type: none"> ▪ Static: This mode of operation is a coverage-based adaptation of the CCA thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa. ▪ Dynamic: In this mode, the CCA thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client. ▪ Disable: This mode does not support the tuning of the CCA Detect Threshold.
RTS Mode	RTS mode configured to control RTS frame transmission to the clients. <ul style="list-style-type: none"> ▪ always-enable: RTS is used for every PPDU/ A-MPDU transmission. ▪ always-disable: RTS is not used for any transmission.

Parameter	Description
	<ul style="list-style-type: none"> ▪ default: The default RTS mode configured in the wireless driver of the AP is used.
Set to Radar Test Mode	For internal use only.
Adaptive Radio Management (ARM) Profile	Name of an ARM profile associated with this 802.11a profile.
High-throughput Radio Profile	Name of a High Throughput Radio profile associated with this 802.11a profile.
AM Scanning Profile	The AM scanning profile referenced by APs using this 802.11a radio profile. For details, see rf am-scan-profile on page 1146
Max Channel Bandwidth	Sets the maximum channel bandwidth for APs associated to Mobility Conductor managed devices.
Min Channel Bandwidth	Sets the minimum channel bandwidth for APs associated to Mobility Conductor managed devices.
Max EIRP	The maximum transmission power level from 3 to 33 dBm. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links.
Min EIRP	The minimum transmission power level (in dBm) to be assigned to the AP radio(s).
EIRP Offset	This parameter is used to manually adjust EIRP levels selected by the AirMatch algorithm by specifying a value from -6 to 6 dBm.
deploy-hour	<p>Specify a number from 0-23 to select the hour during which AirMatch updates are sent to the APs (in 24-hour format). If the managed device to which the AP is associated is in a different time zone than Mobility Conductor, the AirMatch solution will be deployed according to the time zone of the managed device.</p> <p>NOTE: If this parameter is set in both the AirMatch profile and radio profile, the setting in the radio profile will take precedence.</p>

Related Commands

Related Command	Description
rf dot11a-radio-profile	This command configures AP radio settings for the 5 GHz frequency band, including the Adaptive Radio Management (ARM) profile for standalone controllers and the high-throughput (802.11n) radio profile.

Command History

Release	Modification
ArubaOS 8.11.0.0	The output parameters, Frame Bursting Mode and RTS Mode were introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show rf dot11a-secondary-radio-profile

```
show rf dot11a-secondary-radio-profile [<profile>]
```

Description

Shows an 802.11a secondary radio profile.

Parameter	Description
<profile>	Name of an 802.11a profile.

Issue this command without the <profile> parameter to display the 802.11a Secondary Radio profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Examples

The example below shows that the controller has three configured 802.11a Radio profiles. The **References** column lists the number of other profiles with references to the 802.11a Radio profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] #show rf dot11a-secondary-radio-profile
802.11a secondary radio profile List
-----
Name   References  Profile Status
----  -
Total:0
```

The output of this command includes the following parameters:

Parameter	Description
Radio enable	Shows if the AP has enabled or disabled transmissions on this radio band.

Parameter	Description
Mode	<p>Access Point operating mode. Available options are:</p> <ul style="list-style-type: none"> ▪ am-mode: Air Monitor mode ▪ ap-mode: Access Point mode ▪ apm-mode: Access Point Monitor mode ▪ sensor-mode: RFprotect sensor mode
High throughput enable (radio)	<p>Shows if high-throughput (802.11n) is enabled on the radio. A high-throughput profile manages 40 Mhz tolerance settings, and controls whether or not APs using this profile will advertise intolerance of 40 MHz operation. (This option is disabled by default, allowing 40 MHz operation.)</p> <p>A high-throughput profile also determines whether an AP radio using the profile will stop using the 40 MHz channels surrounding APs or stations advertise 40 Mhz intolerance. This option is enabled by default.</p>
Very High Throughput Rates Enable	<p>Enable or disable support for Very High Throughput (802.11ac) on the radio. This option is enabled by default.</p>
Channel	<p>Channel number for the AP 802.11a, 802.11n, or 802.11ac physical layer.</p>
Transmit EIRP	<p>Maximum transmit power (EIRP) in dBm from 0 to 51 in .5 dBm increments. Further limited by regulatory domain constraints and AP capabilities.</p>
Non-Wi-Fi Interference Immunity	<p>Sets a value for 802.11 Interference Immunity. The default setting for this parameter is level 2. When performance drops due to interference from non-802.11 interferers (such as DECT or Bluetooth devices), the level can be increased up to level 5 for improved performance. However, increasing the level makes the AP slightly “deaf” to its surroundings, causing the AP to lose a small amount of range.</p> <p>The levels for this parameter are:</p> <ul style="list-style-type: none"> ▪ Level-0: no ANI adaptation. ▪ Level-1: noise immunity only. ▪ Level-2: noise and spur immunity. This is the default setting ▪ Level-3: level 2 and weak OFDM immunity. ▪ Level-4: level 3 and FIR immunity.
Enable CSA	<p>Shows if CSAs are enabled or disabled. CSAs, as defined by IEEE 802.11h, enable an AP to announce that it is switching to a new channel before it begins transmitting on that channel. This allows clients that support CSA to transition to the new channel with minimal downtime.</p>
CSA Count	<p>Number of channel switch announcements that must be sent prior to switching to a new channel. The default CSA count is 4 announcements.</p>

Parameter	Description
Spectrum Monitoring	If enabled, the AP operates as a hybrid AP that can simultaneously serve clients and monitor a single channel for spectrum analysis data.
Spectrum Monitoring Profile	The spectrum monitoring profile referenced by APs using this 802.11a radio profile. For details, see rf spectrum-profile on page 1254
Advertise 802.11d and 802.11h Capabilities	If enabled, the radio advertises its 802.11d (Country Information) and 802.11h (Transmit Power Control) capabilities.
Spectrum load balancing	<p>The Spectrum load balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP. This feature is disabled by default.</p>
Spectrum load balancing mode	SLB Mode allows control over how to balance clients. Channel-based load-balancing balances clients across channels. Radio-based load-balancing distributes clients across radios on the same band, independent of channels.
Spectrum load balancing mode update interval	This parameter specifies how often spectrum load balancing calculations are made (in seconds). The default value is 30 seconds.
Spectrum load balancing threshold	If the spectrum load balancing feature is enabled, this parameter controls the percentage difference between number of clients on a channel channel that triggers load balancing. The default value is 20%, meaning that spectrum load balancing is activated when there are 20% more clients on one channel than on another channel used by the AP radio.
Spectrum load balancing domain	<p>Define a spectrum load balancing domain to manually create RF neighborhoods.</p> <p>Use this option to create RF neighborhood information for networks that have disabled ARM scanning and channel assignment.</p> <ul style="list-style-type: none"> ▪ If spectrum load balancing is enabled in a 802.11a radio profile but the spectrum load balancing domain is <i>not</i> defined, ArubaOS uses ARM to calculate RF neighborhoods. ▪ If spectrum load balancing is enabled in a 802.11a radio profile and a spectrum load balancing domain <i>is/so</i>

Parameter	Description
	<p>defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by ARM.</p>
Beacon Period	<p>Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.</p>
Beacon Regulate	<p>If enabled, this option introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air. This option is disabled by default.</p>
Advertised Regulatory Max EIRP	<p>Shows if the radio is configured to work around a known issue on Cisco 7921G telephones by capping for a radio's maximum EIRP. When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons. The supported value is -31 dBm.</p>
ARM/WIDS Override	<p>If enabled, this option disables ARM and Wireless IDS functions and slightly increases packet processing performance. If a radio is configured to operate in Air Monitor mode, then the ARM/WIDS override functions are always enabled, regardless of whether or not this check box is selected.</p>
Reduce Cell Size (Rx Sensitivity)	<p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p>
Energy Detect Threshold Offset	<p>This parameter can modify the energy detect threshold used by the radio in making transmit decisions. The energy detect threshold is a negative value, and the value specified for this parameter (1-12) is the offset from the base value of -59 dBm. For example a value of 1 = -60 dBm, and a value of 10: = -69 dBm. A value of 0 indicates the AP is using the default energy detect threshold for this radio. (This value may vary by AP model).</p>
Management Frame Throttle Interval	<p>Averaging interval for rate limiting mgmt frames from this radio, in seconds. A management frame throttle interval of 0 seconds disables rate limiting.</p>

Parameter	Description
Management Frame Throttle Limit	Maximum number of management frames that can come in from this radio in each throttle interval.
Maximum Distance	Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km..
RTS Mode	<p>RTS mode configured to control RTS frame transmission to the clients.</p> <ul style="list-style-type: none"> ▪ always-enable: RTS is used for every PPDU/ A-MPDU transmission. ▪ always-disable: RTS is not used for any transmission. ▪ default: The default RTS mode configured in the wireless driver of the AP is used.
RX Sensitivity Threshold	If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (-dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength. For example, if the RX sensitivity threshold was set to -65 dBm, the AP would ignore signals with a strength from -1 dBm to -64 dBm. If the value is set to zero, the feature will automatically determine an appropriate threshold.
RX Sensitivity Tuning Based Channel Reuse	<p>Shows if the channel reuse feature's current operating mode, static, dynamic or disable.</p> <ul style="list-style-type: none"> ▪ Static: This mode of operation is a coverage-based adaptation of the CCA thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa. ▪ Dynamic: In this mode, the CCA thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client. ▪ Disable: This mode does not support the tuning of the CCA Detect Threshold.

Parameter	Description
Protection for 802.11b Clients	Shows if the profile has enabled or disabled protection for 802.11b clients.
Adaptive Radio Management (ARM) Profile	Name of an Adaptive Radio Management profile associated with this 802.11a profile.
High-throughput Radio Profile	Name of a High Throughput Radio profile associated with this 802.11a profile.
AM Scanning Profile	The AM scanning profile referenced by APs using this 802.11a radio profile. For details, see rf am-scan-profile on page 1146
Max Channel Bandwidth	Sets the maximum channel bandwidth for APs associated to Mobility Conductormanaged devices.
Min Channel Bandwidth	Sets the minimum channel bandwidth for APs associated to Mobility Conductormanaged devices.
Max EIRP	Maximum EIRP from 3 to 33 dBm. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links.
Min EIRP	The minimum transmission power level (in dBm) to be assigned to the AP radio(s).
EIRP Offset	This parameter is used to manually adjust EIRP levels selected by the AirMatch algorithm by specifying a value from -6 to 6 dBm.
deploy-hour	The hour during which AirMatch updates are sent to APs (in 24-hour format). If the managed device to which the AP is associated is in a different time zone than Mobility Conductor, the AirMatch solution will be deployed according to the time zone of the managed device. NOTE: If this parameter is set in both the AirMatch profile and the 802.11a radio profile, the setting in the 802.11a radio profile will take precedence.
AirMatch Mode Aware	Shows the status of the AirMatch Mode Aware feature. NOTE: If this parameter is set in both the AirMatch profile and the 802.11a radio profile, the setting in the 802.11a radio profile will take precedence.

show rf event-thresholds-profile

```
show rf event-thresholds-profile [<profile>]
```

Description

Show an Event Thresholds profile.

Parameter	Description
<profile>	name of an Event Thresholds profile

Issue this command without the <profile> parameter to display the entire Event Thresholds profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Examples

The example below shows that the controller has two configured Event Thresholds profiles. The **References** column lists the number of other profiles with references to the Event Thresholds profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column

```
(host)[mynode]# show rf event-thresholds-profile
RF Event Thresholds Profile List
-----
Name           References  Profile Status
-----
default        6
event1         2
Total: 2.
```

This example displays the configuration settings for the profile **default**.

```
(host)[mynode]# show rf event-thresholds-profile default
RF Event Thresholds Profile "default"
-----
Parameter                                           Value
-----
Detect Frame Rate Anomalies                        Disabled
Bandwidth Rate High Watermark                      0 %
Bandwidth Rate Low Watermark                       0 %
Frame Error Rate High Watermark                    0 %
Frame Error Rate Low Watermark                     0 %
Frame Fragmentation Rate High Watermark            16 %
Frame Fragmentation Rate Low Watermark              8 %
Frame Low Speed Rate High Watermark                 16 %
```

```

Frame Low Speed Rate Low Watermark      8 %
Frame Non Unicast Rate High Watermark    0 %
Frame Non Unicast Rate Low Watermark     0 %
Frame Receive Error Rate High Watermark  16 %
Frame Receive Error Rate Low Watermark   8 %
Frame Retry Rate High Watermark          16 %
Frame Retry Rate Low Watermark           8 %

```

The output of this command includes the following parameters:

Parameter	Description
Detect Frame Rate Anomalies	Shows of the profile enables or disables detection of frame rate anomalies.
Bandwidth Rate High Watermark	If bandwidth in an AP exceeds this value, it triggers a bandwidth exceeded condition . The value represents the percentage of maximum for a given radio. (For 802.11b, the maximum bandwidth is 7 Mbps. For 802.11 a and g, the maximum is 30 Mbps.) The recommended value is 85%.
Bandwidth Rate Low Watermark	If an AP triggers a bandwidth exceeded condition, the condition persists until bandwidth drops below this value.
Frame Error Rate High Watermark	If the frame error rate (as a percentage of total frames in an AP) exceeds this value, it triggers a frame error rate exceeded condition.
Frame Error Rate Low Watermark	If an AP triggers a frame error rate exceeded condition, the condition persists until the frame error rate drops below this value.
Frame Fragmentation Rate High Watermark	If the frame fragmentation rate (as a percentage of total frames in an AP) exceeds this value, it triggers a frame fragmentation rate exceeded condition.
Frame Fragmentation Rate Low Watermark	If an AP triggers a frame fragmentation rate exceeded condition, the condition persists until the frame fragmentation rate drops below this value.
Frame Low Speed Rate High Watermark	If the rate of low-speed frames (as a percentage of total frames in an AP) exceeds this value, it triggers a low-speed rate exceeded condition.
Frame Low Speed Rate Low Watermark	After a low-speed rate exceeded condition exists, the condition persists until the percentage of low-speed frames drops below this value.
Frame Non Unicast Rate High Watermark	If the non-unicast rate (as a percentage of total frames in an AP) exceeds this value, it triggers a non-unicast rate exceeded condition. This value depends upon the applications used on the network.

Parameter	Description
Frame Non Unicast Rate Low Watermark	If an AP triggers a non-unicast rate exceeded condition, the condition persists until the non-unicast rate drops below this value.
Frame Receive Error Rate High Watermark	If the frame receive error rate (as a percentage of total frames in an AP) exceeds this value, it triggers a frame receive error rate exceeded condition.
Frame Receive Error Rate Low Watermark	If an AP triggers a frame receive error rate exceeded condition, the condition persists until the frame receive error rate drops below this value.
Frame Retry Rate High Watermark	If the frame retry rate (as a percentage of total frames in an AP) exceeds this value, it triggers a frame retry rate exceeded condition.
Frame Retry Rate Low Watermark	If an AP triggers a frame retry rate exceeded condition exists, the condition persists until the frame retry rate drops below this value.

show rf ht-radio-profile

```
show rf ht-radio-profile [<profile>]
  default-a
  default-g
```

Description

Show a High-throughput Radio profile.

Parameter	Description
<profile>	Name of a High-throughput Radio profile.

Issue this command without the <profile> parameter to display the entire High-throughput Radio profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Examples

The example below shows that the controller has five configured High-throughput Radio profiles. The **References** column lists the number of other profiles with references to the High-throughput Radio profile, and the **Profile Status** column indicates whether the profile is predefined and editable, and if that predefined profile has been changed from its default settings. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] #show rf ht-radio-profile
High-throughput radio profile List
-----
Name           References  Profile Status
----           -
default-a     4           Predefined (changed)
default-g     4           Predefined (changed)
Total:2
```

This example displays the configuration settings for the predefined profile **default-a**.

```
(host) [mynode] #show rf ht-radio-profile default-a
High-throughput radio profile "default-a" (Predefined (changed))
-----
Parameter                               Value
-----
40 MHz intolerance                       Disabled
Honor 40 MHz intolerance                 Enabled
CSD override                             Disabled
VHT Bandwidth Signaling                  Disabled
```

```
VHT - Transmit Beamforming Sounding Interval 0 msec
BSS Color 0
BSS Color Switch Count 10
```

This example displays the configuration settings for the predefined profile **default-g**.

```
(host) [mynode] #show rf ht-radio-profile default-g
High-throughput radio profile "default-g" (Predefined (changed))
-----
Parameter                               Value
-----
40 MHz intolerance                       Disabled
Honor 40 MHz intolerance                 Enabled
CSD override                             Disabled
VHT Bandwidth Signaling                  Disabled
VHT - Transmit Beamforming Sounding Interval 0 msec
BSS Color 0
BSS Color Switch Count 10
```

The output of this command includes the following parameters:

Parameter	Description
40 MHz intolerance	Shows whether or not APs using this radio profile will advertise intolerance of 40 MHz operation. By default, 40 MHz operation is allowed.
Honor 40 MHz intolerance	If this parameter is enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.
Diversity Spreading Workaround	When this feature is enabled, all legacy transmissions will be sent using a single antenna. This enables interoperability for legacy or high-throughput stations that cannot decode 802.11n cyclic shift diversity data. This feature is disabled by default and should be kept disabled unless necessary.
BSS Color	Displays the bss color code.
BSS Color Switch Count	Displays the number of times the BSS color switch announcements are sent before switching to a new color.

show rf optimization-profile

show rf optimization-profile [<profile>]

Description

Show an Optimization profile.

Parameter	Description
<profile>	name of an ARM profile

Issue this command without the <profile> parameter to display the entire Optimization profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Examples

The example below shows that the controller has two configured Optimization profiles. The **References** column lists the number of other profiles with references to the Optimization profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode]# show rf optimization-profile
RF Optimization Profile List
-----
Name      References  Profile Status
----      -
default   6
profile2  1

Total:2
```

This example displays the configuration settings for the profile **profile2**.

```
(host)[mynode]#show rf optimization-profile profile2
RF Optimization Profile "profile2"
-----
Parameter                               Value
-----
Station Handoff Assist                   Disabled
Detect Association Failure                Disabled
Coverage Hole Detection                   Disabled
Hole Good RSSI Threshold                   20
Hole Good Station Ageout                   30 sec
Hole Detection Interval                   180 sec
Hole Idle Station Ageout                   90 sec
```

```

Hole Poor RSSI Threshold          10
Detect interference                Disabled
Interference Threshold            90 %
Interference Threshold Exceed Time 25 sec
Interference Baseline Time        25 sec
RSSI Falloff Wait Time            4
Low RSSI Threshold                10
RSSI Check Frequency              3 sec

```

This example displays the configuration settings for the profile **default**.

```

(host)[mynode] #show rf optimization-profile default
RF Optimization Profile "default"
-----
Parameter                Value
-----
Station Handoff Assist   Disabled
RSSI Falloff Wait Time   4 sec
Low RSSI Threshold       10
RSSI Check Frequency     3 sec

```

The output of this command includes the following parameters:

Parameter	Description
Station Handoff Assist	If enabled, this parameter allows the controller to force a client off an AP when the RSSI drops below a defined minimum threshold.
Detect Association Failure	Shows if the profile enables or disables STA association failure detection.
Coverage Hole Detection	Shows if the profile enables or disables coverage hole detection.
Hole Good RSSI Threshold	Time, in seconds, after a coverage hole is detected until a coverage hole event notification is generated. This parameter requires the RF Protect license.
Hole Good Station Ageout	Stations with signal strength above this value are considered to have good coverage. This parameter requires the RF Protect license.
Hole Detection Interval	Time, in seconds, after which a station with good coverage is aged out. This parameter requires the RF Protect license.
Hole Idle Station Ageout	Time, in seconds, after which a station in a poor coverage area is aged out. This parameter requires the RF Protect license.

Parameter	Description
Hole Poor RSSI Threshold	Stations with signal strength below this value will trigger detection of a coverage hole. This parameter requires the RF Protect license.
Detect interference	Enables or disables interference detection.
Interference Threshold	Percentage increase in the frame retry rate or frame receive error rate before interference monitoring begins on a given channel.
Interference Threshold Exceed Time	Time, in seconds, the FRR or FRER exceeds the threshold before interference is reported.
Interference Baseline Time	Time, in seconds, the air monitor should learn the state of the link between the AP and client to create frame retry rate and frame receive error rate baselines.
RSSI Falloff Wait Time	Number of times the detected client RSSI level must fall below the minimum RSSI threshold the before the AP sends a deauthorization message to the client. The maximum value is 8 times.
Low RSSI Threshold	Minimum RSSI above which deauthorization messages should never be sent.
RSSI Check Frequency	Interval, in seconds, to sample RSSI.

```

the following information:

Parameter	Description
Age Out: WIFI	The number of seconds for which a wifi device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 600 seconds.
Age Out: Generic Interferer	The number of seconds for which an unknown device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 30 seconds.
Age Out: Microwave	The number of seconds for which a microwave device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 15 seconds. Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.
Age Out: Microwave (inverter type)	The number of seconds for which an inverter microwave must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 15 seconds. Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.
Age Out: Video Device	The number of seconds for which a video device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 60 seconds.
Age Out: Audio Device	The number of seconds for which an audio device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 10 seconds.
Age Out: Cordless Phone Fixed Frequency	The number of seconds for which a fixed frequency cordless phone must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 10 seconds.
Age Out: Generic Fixed Frequency	The number of seconds for which a generic fixed frequency device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 10 seconds.

Parameter	Description
Age Out: Xbox	The number of seconds for which an Xbox device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 25 seconds. Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.
Age Out: Bluetooth	The number of seconds for which a bluetooth device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 25 seconds. Note that this parameter is applicable to 2.4GHz spectrum monitor radios only.
Age Out: Cordless Network Frequency Hopper	The number of seconds for which a frequency-hopping cordless network device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 60 seconds.
Age Out: Cordless Base Frequency Hopper	The number of seconds for which a frequency-hopping cordless phone base must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 240 seconds.
Age Out: Generic Frequency Hopper	The number of seconds for which a generic frequency-hopping device must stop sending a signal before the spectrum monitor considers that device no longer active on the network. The default value is 25 seconds.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show rights

```
show rights
  downloaded-user-roles
  [<name-of-a-role>]
```

Description

Displays the list of user roles in the roles table with high level details of role policies. To view role policies of a specific role specify the role name.

Parameter	Description
downloaded-user-roles	Show information about downloaded user roles.
name-of-a-role	Enter the role name to view its policy details.

Example

The output of this command shows the list of roles in the role table.

```
(host) [mynode]# show rights
RoleTable
-----
Name                ACL  Bandwidth                ACL List
      Type
----  -----
ap-role             4   Up: No Limit,Dn: No Limit  control/,ap-acl/
System
authenticated      39  Up: No Limit,Dn: No Limit  allowall/,v6-allowall/
User
default-vpn-role   37  Up: No Limit,Dn: No Limit  allowall/,v6-allowall/
User
guest               3   Up: No Limit,Dn: No Limit  http-acl/,https-acl/,dhcp-
acl/
User
guest-logon        6   Up: No Limit,Dn: No Limit  logon-
control/,captiveportal/
User
logon               1   Up: No Limit,Dn: No Limit  logon-
control/,captiveportal/
User
stateful-dot1x     5   Up: No Limit,Dn: No Limit
System
voice               38  Up: No Limit,Dn: No Limit  sip-acl/,noe-acl/,svp-
acl/,vocera-acl/
User
```

The following output displays the ACE entries of role based ACL in IPv6 Split-Tunnel forwarding mode in Remote APs:

```

(host) [mynode] #show rights split
split

         Low   6
Expired Policies (due to time constraints) = 0

```

Command History

Release	Modification
ArubaOS 8.4.0.0	The output of the command was updated to display the IPv6 ACE entries of role-based ACL in Split-Tunnel forwarding mode.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show roleinfo

```
show roleinfo
```

Description

Displays the role of the controller.

No parameters.

Example

The output of this command shows the role of the controller.

```
(host) [mynode] # show roleinfo
switchrole:master
```

Related Commands

Related Command	Description
user-role	This command configures a user role.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show route-access-list

```
show route-access-list
```

Description

This command displays information about ACLs for PBR.

No parameters.

Policy-based routing is an optional feature that allows packets to be routed based on ACLs configured by the administrator. By default, when a managed device receives a packet for routing, it looks up the destination IP in the routing table and forwards the packet to the next hop router. If policy-based routing is configured, the next hop device can be chosen based on a defined access control list.

In a typical deployment scenario with multiple uplinks, the default route only uses one of the uplink next-hops for forwarding packets. If a next hop becomes unreachable, the packets will not reach their destination. If your deployment uses policy-based routing based on a next hop list, any of the uplink next hops could be used for forwarding traffic. This requires a valid ARP entry (Route-cache) in the system for all the policy-based routing next hops.

Example

The following command displays a list of configured routing access lists.

```
(host) [mynode] #show route-access-list
Router Access list table
-----
Name          Use Count  Roles
----          -
attempt1     0
pbr           0
name         1          test
Tuesday      0
```

The output of this command includes the following parameters:

Parameter	Description
Name	Name of the access list.
Use Count	Number of VLANs associated with this routing access list.
Roles	User role associated with the routing access list.

Related Commands

Command	Description
ip access-list route	Configures an ACL for PBR.
ip nexthop-list	Defines a next-hop list for a routing policy.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	PEFNG license.	Enable or Config mode on Mobility Conductor.

show rrm dot11k

```
show rrm dot11k
  ap-channel-report
  beacon-report
  neighbor-report
  transmit-stream-report
```

Description

This command shows the 802.11k information. Click parameter links to view the corresponding show commands.

Parameter	Description
ap-channel-report	Shows AP Channel Report
beacon-report	Shows Beacon Report.
neighbor-report	Shows Neighbor Report.
transmit-stream-report	Shows Transmit Stream Measurement Report.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show rrm dot11k admission-capacity

```
show rrm dot11k admission-capacity
```

Description

Displays the available admission capacity for voice traffic on an AP.

No parameters.

Example

The output of this command shows the available admission capacity for voice traffic on all APs.

```
(host) # show rrm dot11k admission-capacity
802.11K Available Admission Capacity for Voice
-----
Flags: B: Bandwidth based CAC, C: Call-count based CAC
      D: CAC Disabled,      E: CAC Enabled

show rrm dot11k ap-channel-report

```
show rrm dot11k ap-channel-report
  ap-name <name-of-an-ap>
  bssid <bssid-of-an-ap>
  ip-addr <ip-address-of-an-ap>
  ip6-addr <ip-addr>
```

Description

Displays the channel information gathered by the AP. You can either specify an ap-name, bssid or ip-address of an AP to see more details.

Parameter	Description
ap-name	Enter the name of the AP.
bssid	Enter the BSSID address of the AP.
ip-addr	Enter the IP address of the AP.
ip6-addr	Enter the IPv6 address of the AP

Example

The output of this command shows the channel information for r-wing-94:94.

```
(host) [mynode]# show rrm dot11k ap-channel-report ap-name r-wing-94
802.11K AP Channel Report Details
-----
Freq Band  Channel List
-----
2.4 GHz    11,
5 GHz      36, 40, 157, 161, 165,
Num Entries:2
```

show rrm dot11k beacon-report

```
show rrm dot11k beacon-report
```

Description

Displays the beacon report information sent by a client to its AP.

No parameters.

Example

The output of this command shows the beacon report for the client 00:1f:6c:7a:d4:fd.

```
(host) [mynode]# show rrm dot11k beacon-report station-mac 00:1f:6c:7a:d4:fd

show rrm dot11k neighbor-report

```
show rrm dot11k neighbor-report
  ap-name
  bssid
  ip-addr
  ip6-addr
```

Description

Displays the neighbor information for a particular AP. If the AP name or the AP's IP address is specified, the user should specify the ESSID to get the neighbor information. If the ESSID is not specified, the command will display the neighbor information for all the Virtual AP's configured on the AP.

Parameter	Description
ap-name	Identify the AP for which you want to view information.
<name-of-an-ap>	Name of an AP.
<ssid>	ESSID of the AP. If the ESSID includes spaces, you must enclose it in quotation marks.
bssid	Enter the BSSID address of the AP.
ip-addr	Enter the IP address of the AP.

Example

The output of this command shows the neighbor information for r-wing-94.

```
(host) [mynode]# show rrm dot11k neighbor-report ap-name r-wing-94
802.11K Neighbor Report Details
-----

  servers
  trap-group
  trap-hosts
  trap-list
  trap-queue
  user-table
```

Description

This command shows the snmp configuration settings. Click parameter links to view the corresponding show commands.

Parameter	Description
community	Displays the configured snmp communities.
engine-id	Displays the configured snmp engine ID.
inform	Inform queue.
servers	Display SNMP servers from which SNMP requests received
trap-group	Displays the configured SNMP trap-groups.
trap-hosts	Displays the configured trap hosts.
trap-list	All the traps in the controller
trap-queue	Displays the Trap Queue
user-table	Displays the configured snmp users.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show snmp community

show snmp community

Description

Displays the SNMP community string details.

No parameters.

Example

The output of this command shows slot details on the controller.

```
(host) # show snmp community
SNMP COMMUNITIES
-----
COMMUNITY  ACCESS      VERSION
-----
public     READ_ONLY  V1, V2c
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config mode on Mobility Conductor and managed device.

show snmp engine-id

show snmp engine-id

Description

This command displays the SNMP engine ID.

No parameters.

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

```
(host)[mynode] #show snmp engine-id
SNMP engine ID: 000039e7000000a10a11a029 (Factory Default)
```

Related Commands

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show snmp inform

```
show snmp inform
```

Description

Displays the length of SNMP inform queue.

No parameters.

Example

The output of this command shows slot details on the controller.

```
(host) # show snmp inform stats
Inform queue size is 100
SNMP INFORM STATS
-----
HOST  PORT  INFORMS-INQUEUE  OVERFLOW  TOTAL INFORMS
-----
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show snmp servers

```
show snmp servers
```

Description

Display SNMP servers from which SNMP requests received.

Example

```
(host) # show snmp servers

SNMP SERVERS
-----
SERVER          REQUEST COUNT  TIMESTAMP
-----
15.110.188.5    630            Wed Nov 16 02:04:12 2022
15.110.188.6    630            Wed Dec 7 02:51:21 2022
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show snmp trap-group

```
show snmp trap-group
```

Description

This command displays the configured SNMP trap groups.

Example

The following example displays details of the configured SNMP trap groups:

```
(host) [mynode] # show snmp trap-group

SNMP TRAP GROUP
-----
TRAP-GROUP      ENABLED TRAPS
-----
vlanTraps       wlsxVlanLinkUp
                 wlsxVlanLinkDown
                 wlsxVlanEntryChanged
linkTraps        linkUp
                 linkDown
System          wlsxFlashSpaceOK
                 wlsxMemoryUsageOK
                 wlsxPowerSupplyOK
                 wlsxFanOK
```

The output of this command includes the following parameters:

Column	Description
Trap-Group	Shows the name of the SNMP trap group.
Enabled Traps	Shows the SNMP traps configured under the trap group.

Command History

Release	Modification
ArubaOS 8.8.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show snmp trap-hosts

```
show snmp trap-hosts
```

Description

Displays the configured SNMP trap hosts.

No parameters.

Example

The output of this command shows details of a SNMP trap host.

```
(host) # show snmp trap-hosts
SNMP TRAP HOSTS
-----
HOST          VERSION      SECURITY NAME  PORT   TYPE   TIMEOUT  RETRY
-----
10.16.14.1    SNMPv2c     public        162   Trap  N/A      N/A
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show snmp trap-list

show snmp trap-list

Description

Displays the list of SNMP traps.

No parameters.

Example

The output of this command shows the list of SNMP traps and the status.

```
(host) # show snmp trap-list
SNMP TRAP LIST
-----
TRAP-NAME                                CONFIGURABLE  ENABLE-STATE
-----

up
```

Command History

Release	Modification
ArubaOS 8.11.0.0	A new SNMP trap, wlsxLicenseThresholdLimitHit was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show snmp user-table

show snmp user-table

Description

Displays the list of SNMP user profiles.

Example

The output of this command shows the list of SNMP traps sent to host.

```
(host) # show snmp user-table
SNMP USER TABLE
-----
USER      AUTHPROTOCOL  PRIVACYPROTOCOL  FLAGS
-----
Sam       SHA           AES
fire      SHA           AES
```

The output of this command includes the following parameters:

Parameter	Description
auth-prot	Authentication protocol for the user, either HMAC-MD5-98 Digest Authentication Protocol (MD5) or HMAC-SHA-98 Digest Authentication Protocol (SHA), and the password for use with the designated protocol.
priv-prot	Privacy protocol for the user, either AES or CBC-DES, and the password for use with the designated protocol.

show spanning-tree

```
show spanning-tree
  <interface [gigabitethernet <slot/module/port> | port-channel id]
  <vlan vlan-id>
```

Description

View the RSTP and PVST+ configuration.

Parameter	Description
interface	Enter the keyword interface followed by the interface and slot/module/port or port-channel id: <ul style="list-style-type: none">■ For Gigabit Ethernet enter the keyword gigabitethernet followed by the <slot/module/port>■ For Port Channel enter the keyword port-channel followed by an id number Range: 0 to 7
vlan	Enter the keyword vlan follow by the VLAN ID. Default: 1 Range: 1 to 4094

Example—show spanning-tree

```
(host) # show spanning-tree

Spanning tree instance for vlan 10
Spanning Tree is executing the IEEE compatible Rapid Spanning Tree protocol
Bridge Identifier has priority 32768, address 00:0b:86:f0:20:00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag is not set, detected flag not set, changes 1
Times: hold 1, topology change 35 hello 2, max age 20, forward delay 15
Timers: hello 0, notification 0
Last topology change: 2 days, 0 hours, 31 mins, 21 secs

Spanning tree instance for vlan 20
Spanning Tree is executing the IEEE compatible Rapid Spanning Tree protocol
Bridge Identifier has priority 32768, address 00:0b:86:f0:20:00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag is not set, detected flag not set, changes 1
Times: hold 1, topology change 3 hello 2, max age 20, forward delay 15
Timers: hello 0, notification 0
Last topology change: 1 days, 0 hours, 3 mins, 2 secs
```

Example—show spanning-tree vlan

```
(host) # show spanning-tree vlan 2
Spanning Tree is executing the IEEE compatible Rapid Spanning Tree protocol
Bridge Identifier has priority 32768, address 00:0b:86:f0:20:00
Configured hello time 2, max age 20, forward delay 15
We are the root of the spanning tree
Topology change flag is not set, detected flag not set, changes 1
Times: hold 1, topology change 35 hello 2, max age 20, forward delay 15
Timers: hello 0, notification 0
Last topology change: 2 days, 0 hours, 31 mins, 21 secs
```

Example—show spanning-tree interface gigabitethernet

```
(host) (config-if)#show spanning-tree interface gigabitethernet 0/0/1
Interface FE 1/1 (port 2) in Spanning tree is FORWARDING
Port path cost 19, Port priority 128 Role DISNIGNATED
PortFast DISABLED P-to-P ENABLED
Designated root has priority 0 address 00:01:e8:d5:a3:6d
Designated bridge has priority 32768 address 00:0b:86:50:58:30
Designated port is 2, path cost 0
Timers: message age 0, forward delay 20, hold 0
Counts: BPDUs received 0, sent 0
```

show spantree

```
show spantree  
  <blocking> | <enable> | <forwarding> | <off> | <vlan>
```

Description

View the global RSTP and PVST+ topology.

Parameter	Description
blocking	View the spanning tree ports in the Blocking state.
enable	View the spanning tree ports in the Enable state.
forwarding	View the spanning tree ports in the Forwarding state.
off	View the ports with spanning tree disabled
vlan	View the spanning tree instance for the VLAN.

Example

```
(host) # show spantree  
Spanning tree instance      vlan 1  
Designated Root MAC        00:0b:86:6b:57:80

show station-table

```
show station-table [mac <mac_address> | verbose ]
```

Description

Displays the internal station table entries and also details of a station table entry.

Parameter	Description
mac <mac_address>	Displays the details of the AP that matches the specified MAC address.
verbose	Displays the details of all the APs in a table format.

Example

The output of this command shows details of an entry in the station table.

```
(host) # show station-table mac 00:1f:6c:7a:d4:fd
Association Table
-----
      BSSID           IP           Essid     AP name   Phy   Age
-----

show stm

```
show stm
  aruba-death-reasons
  mon-update-queue {stats | threshold}
  perf-history {length | interval}
```

Description

This command is used to display the deauthentication reasons and the monitoring update queue information from the station management module.

Parameter	Description
aruba-death-reasons	Displays the Aruba deauthentication reasons.
mon-update-queue	Displays the STM monitoring update queue information.
stats	Displays the STM update queue statistics.
threshold	Displays the STM monitoring update queue threshold.
perf-history	Displays the association rate history for every five minute of the past 24 hours, by default. Starting from ArubaOS 8.6.0.17 and 8.7.1.9, the output of the show stm perf-history command will display the Avg rate/s to indicate the average number of association requests received by the controller.
duration	Displays the output for the duration specified. Default: 24 hours.
interval	Displays the output for the time interval specified. Default: 5 minutes.

Example

The following command displays the STM deauthentication reasons:

```
(host) [mynode] #show stm aruba-death-reasons
Aruba Death Reasons
-----
Code  Reason
----  -
1     Unspecified Failure
2     Prior authentication is not valid
3     STA has left and is deauthenticated
4     Inactive Timer expired and STA was disassociated
5     Disassociated due to insufficient resources at AP
```

```

6     Class 2 frames from non authenticated STA
7     Class 3 frames from non associated STA
8     STA has left and is disassociated
9     STA Requesting Association without authentication
...
...
..

```

The following command displays the STM monitoring queue update statistics:

```

(host) [mynode] #show stm mon-update-queue stats
(host) [mynode] #show stm mon-update-queue stats
Stm mon update queue statistics
Mon queue size:0
AP Devices Queued
-----
Add   Info Update   Delete   Stats Update
---   -
0     0             0        0
AP Devices Dropped
-----
Add   Info Update   Delete   Stats Update
---   -
0     0             0        0
RADIO Devices Queued
-----
Add   Info Update   Delete   Stats Update
---   -
0     0             0        0
...
...

```

The following command displays the monitoring update queue threshold value:

```

(host) [mynode] #show stm mon-update-queue threshold
Stm mon update queue limit:83328

```

The following command displays the number of association requests received by the controller for the past 24 hours.

```

((host) #show stm perf-history
Association Rate History
-----
Day   Hour   Min   Total   Peak rate/s   Peak time
---   ---   ---   ---

show storage

show storage

Description

Displays the storage information on the controller.

No parameters.

Example

The output of this command shows the storage details on the controller.

```
(host) # show storage
Filesystem      Size      Used Available Use% Mounted on
/dev/root       57.0M     54.6M      2.3M   96% /
none            70.0M     2.0M     68.0M    3% /tmp
/dev/hda3       149.7M     9.3M    132.6M    7% /flash
/dev/usb/flash3 1.5G     168.6M    1.3G   12% /flash
/dev/usbdisk/2 3.5G     71.4M     3.2G    2% /mnt/usbdisk/2
/dev/usbdisk/1 3.9G    131.0M     3.8G    3% /mnt/usbdisk/1
```

The number at the end of the USB device's name is the partition. Unlike the controller's flash, the USB device has more than two partitions; not just 0 and 1. When copying a file from a USB device, you must know which partition the target file is on.

show switches

```
show switches [all| debug | regulatory | state {complete | incomplete | inprogress  
| required} | summary ]
```

Description

Displays the details of managed device connected to the Mobility Conductor, including the Mobility Conductor itself.

Parameter	Description
all	List of all managed devices.
debug	Displays additional switch information.
regulatory	Displays information about the currently active regulatory file.
state	Configuration status of all managed devices.
summary	Status of all managed devices connected to the Mobility Conductor.

Example

The output of this command shows that there is a single managed device connected to the Mobility Conductor.

```
(host) # show switches all
All Switches
-----
IP Address  Name           Location           Type   Version           Status
Configuration State  Config Sync Time (sec)
-----  ----  -----  ----  -----  -----  --
-----  -----
10.16.12.1  r-wing-94      Building1.floor1  master  6.0.0.0_13782  up

show tech-support

```
show tech-support
  airgroup
    <filename>
  lte_uplink
    <filename>
  user
```

Description

Displays all information about the controller required for technical support purposes.

Parameter	Description
<code>airgroup</code>	Starting from ArubaOS 8.6.0.5, the command displays AirGroup related tech-support logs.
<code>lte_uplink</code>	Displays all LTE related uplink CLI
<code><filename></code>	Stores the output in specified file name. Maximum length of the file name is 127 characters
<code>user</code>	Run a user specific tech-support command.

Command History

Release	Modification
ArubaOS 8.9.0.0	The following changes were introduced: All instances of <code>master</code> have been replaced with <code>conductor</code> . All instances of <code>blacklist</code> have been replaced with <code>denylist</code> . All instances of <code>whitelist</code> have been replaced with <code>allowlist</code> .
ArubaOS 8.6.0.5	The <code>airgroup</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

show threshold

show threshold

all | controlpath-cpu | controlpath-memory | datapath-cpu |
no-of-aps | no-of-locals | no-of-vaps | total-tunnel-capacity | user-capacity |

Description

This command shows managed device capacity thresholds which, when exceeded, will trigger alerts.

Parameter	Description
all	Display all alert thresholds.
controlpath-cpu	Display the alert threshold for controlpath CPU capacity. The output of this command shows the percentage of the total controlpath CPU capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 45%.
controlpath-memory	Display the alert threshold for controlpath memory consumption. The output of this command shows the percentage of the total memory capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 85%.
datapath-cpu	Display the alert threshold for datapath CPU capacity. The output of this command shows the percentage of the total datapath CPU capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 30%.
no-of-APs	The maximum number of APs that can be connected to a managed device is determined by that managed device's model type and installed licenses. This threshold triggers an alert when the number of APs currently connected to the managed device exceeds a specific percentage of its total AP capacity. The default threshold for this parameter is 80%.
no-of-locals	Display the alert threshold for Mobility Conductor's capacity to support managed devices. Mobility Conductor can support a combined total of 256 managed devices. The output of this command shows the percentage of the total Mobility Conductor capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 80%.

Parameter	Description
no-of-vaps	The maximum number of VAPs that can be connected to a managed device is determined by that managed device's model type and installed licenses. This threshold triggers an alert when the number of VAPs currently connected to the managed device exceeds a specific percentage of its total VAP capacity. The default threshold for this parameter is 80%.
total-tunnel-capacity	Display the alert threshold for the managed device's tunnel capacity. The output of this command shows the percentage of the managed device's total tunnel capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 80%
user-capacity	Display the alert threshold for the managed device's user capacity. The output of this command shows the percentage of the total resource capacity that must be exceeded before the alert is sent. The default threshold for this parameter is 80%.

The managed device will send a *wlsxThresholdAbove* SNMP trap and a syslog error message when the managed device has exceeded a set percentage of the total capacity for that resource. A *wlsxThresholdBelow* SNMP trap and error message will be triggered if the resource usage drops below the threshold once again.

Example

```
(host) (config) #show threshold all
controller Capacity Threshold Values
-----
RESOURCE                THRESHOLD (%)
-----
Datapath-Cpu             30 %
Controlpath-Cpu         80 %
Controlpath-Memory      85 %
Total-Tunnel-Capacity   80 %
Ap-Tunnel-Capacity      80 %
User-Capacity           80 %
No-of-APs               80 %
No-of-locals            80 %
```

Related Commands

show threshold-limits

show threshold-limits

```
controlpath-memory| fan-speed| no-of-aps| no-of-locals| no-of-vaps| total-tunnel-  
capacity| user-capacity
```

Description

This command shows current values of the different resources monitored by the managed device.

Parameter	Description
controlpath-memory	The output of this command displays the default memory threshold which, when exceeded, will trigger an alert, the current configured threshold, the total memory (in MB) and the currently available memory (in MB).
fan-speed	The output of this command displays the fan alert threshold. This parameter is only available for managed devices with fans, such as the 7200 Series.
no-of-aps	The output of this command displays the following values: <ul style="list-style-type: none">▪ The default threshold for the number of APs, which, when exceeded, will trigger an alert▪ The current configured threshold.▪ The maximum number of APs supported by the managed device,▪ The number of available licenses for campus and remote APs,▪ The total number of APs, and the current number of campus, remote and virtual APs.
no-of-locals	The output of this command displays the default threshold for the number of managed devices which, when exceeded, will trigger an alert, and the current configured threshold. The output also displays the maximum number of managed devices that can be connected to this Mobility Conductor, and the number of managed devices currently connected.
no-of-vaps	The output of this command displays the following values: <ul style="list-style-type: none">▪ The default threshold for the number of Virtual APs, which, when exceeded, will trigger an alert▪ The current configured threshold.▪ The maximum number of Virtual APs supported by the managed device,▪ The total number of current Virtual APs.

Parameter	Description
<code>total-tunnel-capacity</code>	The output of this command displays the default tunnel capacity threshold which, when exceeded, will trigger an alert, as well as the current configured tunnel threshold. The output also includes the maximum number of tunnels supported by the managed device, as well as the number of tunnels currently used by the managed device.
<code>user-capacity</code>	The output of this command displays the default user capacity threshold which, when exceeded, will trigger an alert, as well as the current configured user threshold. The output also includes the maximum number of users supported by the managed device, as well as the number of users currently associated with the managed device.

The managed device will send a *wlsxThresholdAbove* SNMP trap and a syslog error message when the managed device has exceeded a set percentage of the total capacity for that resource. A *wlsxThresholdBelow* SNMP trap and error message will be triggered if the resource usage drops below the threshold once again.

Example

The following command shows the current alert thresholds for controlpath memory resources:

```
[host](node)(config) #show threshold-limits controlpath-memory

Threshold Values For Controlpath Memory
-----
Default(%)   Current(%)   Total Memory (MB)   Available Memory (MB)
-----
85           77           679                 225
```

Related Commands

show tm

```
show tm
  mon-update-queue {stats | threshold}
```

Description

This command is used to display the monitoring update queue information of the telemetry manager module.

Parameter	Description
mon-update-queue	Displays the TM monitoring update queue information.
stats	Displays the TM update queue statistics.
threshold	Displays the TM monitoring update queue threshold.

Example

The following command displays the TM monitoring queue update statistics:

```
(host) [mynode] #show tm mon-update-queue stats
Telemetry-Manager MON update queue statistics
Mon queue size:0
Mon queue threshold:3334
Mon queue current percentage of threshold:0%
Mon queue timer:stopped
TM MON Stats (Queued/Dropped)
-----
MON Device  Add  Update Info  Update Stats  Delete
-----
NETWORK    1   0           1632          0
AP          10  13          4783          8
RADIO      17   0           6478          12
VAP        21   0           6478          12
STA         1/0  1/0         1544/0        0
USER        1/0  8/0          0/0           0
IP_USER     4/0  0/0          0/0           0
DENYLIST    0   0            0             0
```

The following command displays the monitoring update queue threshold value:

```
(host) [mynode] #show tm mon-update-queue threshold
Telemetry-Manager MON update queue limit:3334
0: disabled
```

Related Commands

Command	Description

show tpm

```
show tpm
  cert-info
  errorlog
  version
```

Description

Displays the TPM and factory certificate information and error log.

Use this command to verify that TPM and factory certificates are installed as expected.

Parameter	Description
cert-info	Displays the factory certificate information.
errorlog	Displays the TPM/certificate related error logs.
version	Displays the TPM firmware version information.

Example

In the example below, the TPM and certificates are installed.

```
(host) [mynode] #show tpm cert-info

subject= /CN=AF0000168::00:0b:86:f0:33:e0
issuer= /DC=com/DC=arubanetworks/DC=ca/CN=DEVICE-CA2
serial=1F023F05000000015087
notBefore=Jan 30 01:38:57 2009 GMT
notAfter=Jan 25 01:38:57 2029 GMT
```

In the example below, the controller is unable to verify the TPM or factory certificate information.

```
(host) [mynode] #show tpm cert-info

Cannot get TPM and Factory Certificate Info
TPM and/or Factory Certificates might be missing.
```

In the example below, the TPM initialization errors are displayed.

```
(host) [mynode] #show tpm errorlog
```

```

show tunnel-group

show tunnel-group <tunnel-group-name>

Description

Displays the operational status of the tunnel-groups configured on the controller.

Parameter	Description
<tunnel-group-name>	Displays the operational status of the specified tunnel-group.

Example

The output of this command shows the status of the configured tunnel-groups:

```
(host) #show tunnel-group

Tunnel-Group Table Entries
-----
Tunnel Group Type Tunnel Group Id Preemptive Failover Active Tunnel Id
Tunnel Members
-----
tgroup1      L3   16385          enabled           10             10
20
tgroup2      L2   16387          enabled           10             10
20 40
```

The output of the following command shows the status of the specified tunnel-group:

```
(host) #show tunnel-group tgroup1

Tunnel-Group Table Entries
-----
Tunnel Group Type Tunnel Group Id Preemptive Failover Active Tunnel Id
Tunnel Members
-----
tgroup1      L3   16385          enabled           10             10
20
```

The output of the following command shows the datapath Tunnel-Group table entries:

```
(host) #show datapath tunnel-group

Datapath Tunnel-Group Table Entries
```

```

-----
Tunnel-Group Active Tunnel Members
-----
16385          10          10 20

show tunneled-node

```
show tunneled-node {config|state|database}
```

Description

Displays the wired tunneled node configuration details, the state of the tunneled node, and lists all the tunneled nodes in the database.

Parameter	Description
config	Displays the wired tunneled node configuration details.
state	Displays the state of the tunneled node.
database	Displays all the tunneled nodes in the database.

Example

The output of this command shows the tunneled node state.

```
(host) [mynode]# show tunneled-node state

Tunneled Node State
-----
IP MAC s/p state vlan tunnel inactive-time
-- -- -- -- -- -- --
192.168.123.14 00:0b:86:40:32:40 1/23 complete 10 9 1

show tunneled-node-mgr

show tunneled-node-mgr

Description

Displays the tunneled node configuration details, the state of the tunneled node, and lists all the tunneled nodes in the database.

Parameter	Description
cluster-bucket-map	Displays the cluster bucket map details.
cluster-node-list	Displays the cluster node list information.
gsm-counters	Displays the GSM counters details.
mcast-tunnel-table	Information on multicast tunnel.
mcast-vlan-user-map	Information on the user count on each multicast tunnel VLAN pair.
node-heartbeat-table	Displays node heartbeat table related information.
stats	Displays the tunneled node manager statistics.
trace-buf	Displays contents of trace buffer.
tunnel-vlan-user-map	Displays Information on user count on each Tunnel VLAN pair.
tunneled-nodes	Displays all the information on tunneled nodes.
tunneled-users	Displays all the information on tunneled users.
user-tunnel-table	Displays information on user tunnel tables.

Example

You can use the following show command to check if the per-user tunnel node is configured and is working as expected.

```
(host) [mynode]# show tunneled-node-mgr stats

show uap-blacklist/show uap-denylist

show uap-blacklist / show uap-denylist [mac-address|page|start]

Description

This command configures a UAP blacklist/denylist database entry. You can add, delete, or modify AP MAC addresses and description to this database. If you enable the blacklist/denylist policy in the AP deploy profile, the policy is applied to the APs included in this list.

Parameter	Description
mac-address <name>	Shows MAC address of the AP.
page	Shows specific page (50 records per page).
start	Shows <start> records into the database

The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following commands lists all the AP MAC addresses in the UAP blacklist/denylist table:

```
(host) [mynode] #show uap-blacklist/show uap-denylist
UAP Blacklist /Denylist Details
-----
MAC-Address      Description
-----
11:11:11:11:11:11 AP-test2
11:11:11:11:11:12 Ap-test1
11:11:11:11:11:01 AP-test3
```

Flags: V - Visitor, A - Away, W - Wired, R - Remote, E - External

The output of this command includes the following information:

Column	Description
Client IP	Displays the IP address of the VoIP client.
Client MAC	Displays the MAC address of the VoIP client.
Client Name	Displays the username of the VoIP client.
ALG	Displays the Application Layer Gateway protocol used by the VoIP client.
Server (IP)	Displays the IP address of call server the client is registered to.
Registration State	Displays the registration status of the VoIP call. Possible values are: <ul style="list-style-type: none">▪ Challenged▪ Registered▪ Registering▪ Unregistered▪ Rejected▪ Unknown
Call Status	Displays the VoIP call status of the client. Possible values are: <ul style="list-style-type: none">▪ Idle▪ In-Call
AP Name	Displays the name of the AP to which the VoIP client is associated.
Flags	Displays if the client is a visitor, away, wired, remote, or external.
Device Type	Displays the device type identification of the client.
Home Agent	Displays the IP address of the managed device to which the client is connected or the home agent of the client if mobile IP is enabled.
Foreign Agent	Displayed if the client has roamed to another managed device when mobile IP is enabled.

The following command displays the UCC client status details:

```
(host) [mynode] #show ucc client-info detail
```

```

Help: [C] - Metric calculated at the Controller
      [A] - Metric calculated at the AP
      [E] - Metric calculated End-to-End

```

The output of this command includes the following information:

Column	Description
Client IP	Displays the IP address of the VoIP client.
Client MAC	Displays the MAC address of the VoIP client.
Client Name	Displays the username of the VoIP client.
Controller Delay(ms) / Jitter(ms) / PktLoss(%)	Displays the WLAN delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage). This is the metric calculated at the managed device.
AP Delay(ms) / Jitter(ms) / PktLoss(%)	Displays the WLAN delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage). This is the metric calculated at the AP.

Column	Description
End-to-End Delay (ms) / Jitter (ms) / PktLoss (%)	Displays the end-to-end delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage). This field takes the wired and wireless network QoS parameters into consideration.
Call-Dur (sec)	Displays the average call duration in seconds.
TxRate (Mbps)	Displays the average transmission rate in Mbps.
RxRate (Mbps)	Displays the average receive rate in Mbps.
ICH Denied	Displays the number of calls that were not prioritized due to channel utilization threshold exceeding on the AP radio.
ALG	Displays the Application Layer Gateway protocol used by the VoIP client.

The following command displays a detailed record for a specific client MAC address:

```
(host) [mynode] #show ucc client-info sta 00:21:6a:b9:5f:34

```

The output of this command includes the following information:

Column	Description
Station Report	
Client IP	Displays the IP address of the VoIP client.
Client MAC	Displays the MAC address of the VoIP client.
Client Name	Displays the username of the VoIP client.
AP-Name	Displays the name of the AP handling the VoIP call.
SNR	Displays the Signal-to-noise (SNR) ratio. SNR is the power ratio between an information signal and the level of background noise.
Avg Tx Rate (Mbps)	Displays the average transmission rate in Mbps.
Tx Drop (%)	Displays the transmission packet drop in percentage.
Tx Retry (%)	Displays the transmission retry in percentage.
Avg Rx Rate (Mbps)	Displays the average receive rate in Mbps.
Rx Retry (%)	Displays the receive retry in percentage.
Un-steerable (reason)	Displays the reason for steering/not steering the client to another band. Possible values are: <ul style="list-style-type: none"> ▪ Sticky ▪ Load Balance ▪ Band Steer

Column	Description
	<ul style="list-style-type: none"> ▪ Band Balance ▪ Administrator Added ▪ (IOS) ▪ NA
Active Calls	
CDR ID	Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.
UCC Call ID	Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session.
Client IP	Displays the IP address of the VoIP client.
Client Name	Displays the username of the VoIP client.
ALG	Displays the Application Layer Gateway protocol used by the VoIP client.
Dir	Displays the direction of the call. Possible values are: <ul style="list-style-type: none"> ▪ OG—Outgoing ▪ IG—Incoming
Called To	Displays the username of the VoIP client being called.
Dur (sec)	Displays the duration of the VoIP call in seconds.
Orig-Time	Displays the time at which the VoIP call originated.
Status	Displays the status of the VoIP call. Possible values are: <ul style="list-style-type: none"> ▪ SUCCESS ▪ FAILED ▪ ABORTED ▪ BLOCKED ▪ FORWARDED ▪ ALERTING ▪ HOLD ▪ ACTIVE
Call Type	Displays the type of VoIP call or session. Possible values are: <ul style="list-style-type: none"> ▪ Not Available ▪ Voice ▪ Video ▪ Desktop Sharing ▪ File Transfer ▪ Voice/Conf Call ▪ Video/Conf Call

Column	Description
	<ul style="list-style-type: none"> ▪ Desktop-Sharing/Conf Call ▪ File-Transfer/Conf Call
Client Health	Displays the ratio of ideal air time required for transmitting a packet from an AP to a client to the actual air time taken for the packet transmission in percentage. Ideal air time assumes highest data rate without any retransmission.
UCC Score[C]	Displays the UCC score based on the quality of the voice call. This is the metric calculated at the managed device.
UCC Score[A]	Displays the UCC score based on the quality of the voice call or desktop sharing session. This is the metric calculated at the AP.
MOS	Displays the Mean Opinion Score of the VoIP call.
Call History	
Reason	<p>Displays the reason code for call termination. Possible values are:</p> <ul style="list-style-type: none"> ▪ NA ▪ Capacity Reached ▪ 401 unauthorized ▪ 487 request timeout ▪ Request timeout ▪ Request canceled ▪ Request terminated ▪ Session timeout ▪ Session timer expired ▪ Session expired - request timeout ▪ Aborted ▪ Terminated ▪ Forwarded ▪ Transferred ▪ Inactivity ▪ Wrong number ▪ Peer reset ▪ Client reset ▪ No answer ▪ Missed ▪ Parked ▪ Invalid number ▪ Tunnel down ▪ Moved temporarily ▪ 4xx error ▪ 5xx error

Column	Description
	<ul style="list-style-type: none"> ▪ Call leg does not exist ▪ DELTS request ▪ TCLAS flow deleted ▪ No reason

WMM (VI, VO, BK, BE):total calls with received priority

```

The output of this command includes the following information:

Column	Description
Client IP	Displays the IP address of the VoIP client.
Client MAC	Displays the MAC address of the VoIP client.
Call Originated	Displays the number of times a call originated from the VoIP client.
Call Terminated	Displays the number of times a call terminated on the VoIP client.
Active	Displays the number of active calls on the VoIP client.
Success	Displays the number of successful calls.
Failed	Displays the number of failed call setup calls.
Blocked	Displays the number of blocked calls due to CAC.
Aborted	Displays the number of terminated calls due to inactivity.
Forwarded	Displays the number of times a call is forwarded for a VoIP client.
WMM AC-VI	Displays the number of calls where the client sent RTP with WMM AC set to Video (VI).
WMM AC-VO	Displays the number of calls where the client sent RTP with WMM AC set to Voice (VO).

Column	Description
WMM-BK	Displays the number of calls where the client sent RTP with WMM AC set to Background (BK).
WMM-BE	Displays the number of calls where the client sent RTP with WMM AC set to Best Effort (BE).

show ucc call-info cdrs

```
show ucc call-info cdrs
  ap <ap_name>
  app
  cid <cid>
  detail
```

Description

This command displays the Call Detailed Records (CDR) statistics for Unified Communication and Collaboration (UCC). Click parameter links to view the corresponding show commands.

When VoIP calls are prioritized using media classification, the **UCC Call ID**, **Client Name**, **Called to**, **Dir** (direction of the call), **End-to-End Delay(ms)/Jitter(ms)/PktLoss(%)**, **Codec**, **MOS**, and **MOS-Band** values are not available.

Parameter	Description
ap <ap_name>	Displays the CDR statistics of an AP for a specific Application Layer Gateway (ALG).
app	Displays the CDR statistics based on a specific ALG.
cid <cid>	Displays CDR statistics for a specific CDR-ID.
detail	Displays detailed CDR statistics.

Example

The following command displays the CDR statistics:

```
(host) [mynode] #show ucc call-info cdrs

Help: [C] - Metric calculated at the Controller
      [A] - Metric calculated at the AP

The output of this command includes the following information:

Column	Description
CDR ID	Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.
UCC Call ID	Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session. NOTE: This column is not populated for WiFi-Calling ALG.
Client IP	Displays the IP address of the VoIP client.
Client MAC	Displays the MAC address of the VoIP client.
Client Name	Displays the username of the VoIP client. NOTE: This column is not populated for WiFi-Calling ALG.
ALG	Displays the VoIP protocol used by the VoIP client.
Dir	Displays the direction of the call. Possible values are: <ul style="list-style-type: none"> ▪ OG—Outgoing ▪ IC—Incoming NOTE: This column is not populated for WiFi-Calling ALG.

Column	Description
Called to	Displays the username of the VoIP client being called. NOTE: This column is not populated for WiFi-Calling ALG.
Dur (sec)	Displays the duration of the VoIP call in seconds.
Orig Time	Displays the time at which the VoIP call originated.
Status	Displays the status of the VoIP call. Possible values are: <ul style="list-style-type: none"> ▪ SUCCESS ▪ FAILED ▪ ABORTED ▪ BLOCKED ▪ FORWARDED ▪ ALERTING ▪ HOLD ▪ ACTIVE
Reason	Displays the reason code for call termination. Possible values are: <ul style="list-style-type: none"> ▪ NA ▪ Capacity Reached ▪ 401 unauthorized ▪ 487 request timeout ▪ Request timeout ▪ Request canceled ▪ Request terminated ▪ Session timeout ▪ Session timer expired ▪ Session expired - request timeout ▪ Aborted ▪ Terminated ▪ Forwarded ▪ Transferred ▪ Inactivity ▪ Wrong number ▪ Peer reset ▪ Client reset ▪ No answer ▪ Missed ▪ Parked ▪ Invalid number ▪ Tunnel down ▪ Moved temporarily ▪ 4xx error ▪ 5xx error

Column	Description
	<ul style="list-style-type: none"> ▪ Call leg does not exist ▪ DELTS request ▪ TCLAS flow deleted ▪ No reason
Call Type	<p>Displays the type of VoIP call or session. Possible values are:</p> <ul style="list-style-type: none"> ▪ Not Available ▪ Voice ▪ Video ▪ Desktop Sharing ▪ File Transfer ▪ Voice/Conf Call ▪ Video/Conf Call ▪ Desktop-Sharing/Conf Call ▪ File-Transfer/Conf Call
Client Health	<p>Displays the ratio of ideal air time required for transmitting a packet from an AP to a client to the actual air time taken for the packet transmission in percentage. Ideal air time assumes highest data rate without any retransmission.</p>
UCC Score[C]	<p>Displays the UCC score based on the quality of the voice call. This is the metric calculated at the managed device.</p> <p>NOTE: This column is not populated for WiFi-Calling ALG.</p>
UCC Score[A]	<p>Displays the UCC score based on the quality of the voice call or desktop sharing session. This is the metric calculated at the AP.</p> <p>NOTE: This column is not populated for WiFi-Calling ALG.</p>
MOS	<p>Displays the Mean Opinion Score (MOS) of the VoIP call.</p> <p>NOTE: This column is not populated for WiFi-Calling ALG.</p>
Server (IP)	<p>Displays the name of the service provider for WiFi-calling ALG</p>

The output of this command includes the following information:

Column	Description
CDR ID	Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.
UCC Call ID	Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session. NOTE: This column is not populated for WiFi-Calling ALG.

Column	Description
AP Name	Displays the name that uniquely identifies the AP.
Re-Assoc	Displays the number of times the client re-associated while on an active call.
UCC Score [C]	Displays the UCC score based on the quality of the voice call. This is the metric calculated at the managed device.
D (ms) / J (ms) / PL (%) [C]	Displays the WLAN delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage). This is the metric calculated at the managed device.
UCC Score [A]	Displays the UCC score based on the quality of the voice call or desktop sharing. This is the metric calculated at the AP. NOTE: This column is not populated for WiFi-Calling ALG.
D (ms) / J (ms) / PL (%) [A]	Displays the WLAN delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage). This is the metric calculated at the AP.
SNR	Displays the Signal-to-noise (SNR) ratio. SNR is the power ratio between an information signal and the level of background noise.
Avg Tx Rate (Mbps)	Displays the average transmission rate in Mbps.
Tx Drop (%)	Displays the transmission packet drop in percentage.
Tx Retry (%)	Displays the transmission retry in percentage.
Avg Rx Rate (Mbps)	Displays the average receive rate in Mbps.
Rx Retry (%)	Displays the receive retry in percentage.
MOS	Displays the MOS value of the VoIP call. This is an end-to-end score (wired and wireless) of the VoIP call. NOTE: This column is not populated for WiFi-Calling ALG.
D (ms) / J (ms) / PL (%) [E]	Displays the end-to-end delay (in milliseconds), jitter (in milliseconds), and packet loss (in percentage). This field takes the wired and wireless network QoS parameters into consideration.
Controller-IP	Displays the IP address of the managed device.

```

The output of this command includes the following information:

Column	Description
CDR ID	Displays the Call Detail Record ID of a particular voice and video calls, desktop sharing, or file transfer session.
UCC Call ID	Displays the unique identifier for all call legs of a particular voice and video calls, desktop sharing, or file transfer session. NOTE: This column is not populated for WiFi-Calling ALG.
Client IP	Displays the IP address of the VoIP client.
Client MAC	Displays the MAC address of the VoIP client.
Client Name	Displays the username of the VoIP client. NOTE: This column is not populated for WiFi-Calling ALG.

Column	Description
ALG	Displays the VoIP protocol used by the VoIP client.
Dir	Displays the direction of the call. Possible values are: <ul style="list-style-type: none"> ▪ OG—Outgoing ▪ IC—Incoming NOTE: This column is not populated for WiFi-Calling ALG.
Called to	Displays the username of the VoIP client being called. NOTE: This column is not populated for WiFi-Calling ALG.
Dur (sec)	Displays the duration of the VoIP call in seconds.
Orig Time	Displays the time at which the VoIP call originated.
Status	Displays the status of the VoIP call. Possible values are: <ul style="list-style-type: none"> ▪ SUCCESS ▪ FAILED ▪ ABORTED ▪ BLOCKED ▪ FORWARDED ▪ ALERTING ▪ HOLD ▪ ACTIVE
Reason	Displays the reason code for call termination. Possible values are: <ul style="list-style-type: none"> ▪ NA ▪ Capacity Reached ▪ 401 unauthorized ▪ 487 request timeout ▪ Request timeout ▪ Request canceled ▪ Request terminated ▪ Session timeout ▪ Session timer expired ▪ Session expired - request timeout ▪ Aborted ▪ Terminated ▪ Forwarded ▪ Transferred ▪ Inactivity ▪ Wrong number ▪ Peer reset ▪ Client reset

Column	Description
	<ul style="list-style-type: none"> ▪ No answer ▪ Missed ▪ Parked ▪ Invalid number ▪ Tunnel down ▪ Moved temporarily ▪ 4xx error ▪ 5xx error ▪ Call leg does not exist ▪ DELTS request ▪ TCLAS flow deleted ▪ No reason
Call Type	<p>Displays the type of VoIP call or session. Possible values are:</p> <ul style="list-style-type: none"> ▪ Not Available ▪ Voice ▪ Video ▪ Desktop Sharing ▪ File Transfer ▪ Voice/Conf Call ▪ Video/Conf Call ▪ Desktop-Sharing/Conf Call ▪ File-Transfer/Conf Call
Client Health	<p>Displays the ratio of ideal air time required for transmitting a packet from an AP to a client to the actual air time taken for the packet transmission in percentage. Ideal air time assumes highest data rate without any retransmission.</p>
UCC Score[C]	<p>Displays the UCC score based on the quality of the voice call. This is the metric calculated at the managed device.</p> <p>NOTE: This column is not populated for WiFi-Calling ALG.</p>
UCC Score[A]	<p>Displays the UCC score based on the quality of the voice call or desktop sharing session. This is the metric calculated at the AP.</p> <p>NOTE: This column is not populated for WiFi-Calling ALG.</p>
MOS	<p>Displays the Mean Opinion Score (MOS) of the VoIP call.</p> <p>NOTE: This column is not populated for WiFi-Calling ALG.</p>
Server (IP)	<p>Displays the name of the service provider for WiFi-calling ALG</p>

show upgrade internal

```
show upgrade internal managed-devices status
  copy list <mac-list>
  reboot list <mac-list>
  summary list <mac-list>
```

Description

This command displays the upgrade status of the managed devices.

Parameter	Description
copy list <mac-list>	Copy status of managed devices based on MAC address. Specify multiple MAC addresses separated by commas.
reboot list <mac-list>	Reboot status of managed devices based on MAC address. Specify multiple MAC addresses separated by commas.
summary list <mac-list>	Status summary of managed devices based on MAC address. Specify multiple MAC addresses separated by commas.

Example

```
(host) [mynode] #show upgrade internal managed-devices status summary list
00:0b:23:b0:81:d0

upgrade managed-node status summary
-----
LC MAC   Config Path  Host Name  IP Addr  LC Model  Current Ver  Last Cmd
Last Cmd Status
-----
-----00:0b:23:b0:81:d0  /md/IND/70XXS  A7010-HA2-FIFTEEN
192.168.5.15  A7010  8.0.0.0-svcs-ctrl_55616  Not initialized  Not
initialized
```

The output of this command includes the following information:

Parameter	Description
LC MAC	MAC address of the managed device.
Config Path	Config node path of the managed device.
Host Name	Name of the Mobility Conductor.

Parameter	Description
IP Addr	IP address of the managed device.
LC Model	Model number of the managed device.
Current Ver	Version of ArubaOS currently running on the managed device.
Last Cmd	Last command issued on the managed device.
Last Cmd Status	Status of the last command issued on the managed device.

Related Commands

Command	Description
upgrade internal	This command upgrades the managed devices with the respective options provided in the input, like using different protocol options as well as loading at different node levels and paths, and also can upgrade the single managed device based on the MAC address of the device. This command is internal or hidden.

Command History

Release	Modification

  reboot
    all
    path <node-path>
    single <mac-addr>
  summary
    all
    path <node-path>
    single <mac-addr>
```

Description

This command displays the upgrade status of the managed devices.

Parameter	Description
ca-bundle	Trusted CA certificates version of managed device.
all	Trusted CA certificates version of all managed devices.
path <node-path>	Trusted CA certificates version of managed devices under the specific node path.
single <mac-addr>	Trusted CA certificates version of a managed device based on MAC address.
copy	Copy status of managed device.
all	Copy status of all managed devices under the respective node path.
path <node-path>	Copy status of all managed devices under the specific node path.
copy single <mac-addr>	Copy status of a specific managed device based on MAC address.
reboot	Reboot status of managed device.

Parameter	Description
all	Reboot status of all managed devices under the respective node path.
path	Reboot status of all managed devices under a specific node path.
single	Reboot status of a specific managed device based on MAC address.
Summary	Status summary of the managed device .
all	Status summary of all managed device under the respective node path.
path	Status summary ofl managed devices under a specific node path.
single	Status Summary of a specific managed device based on MAC address.

Example

```
(host) [mynode] #show upgrade managed-devices status summary single

show upgrade-profile

show upgrade-profile

Description

The settings in the centralized image upgrade profile uses ArubaOS images to upgrade the managed devices with the ArubaOS images hosted on an image server. When an upgrade action command is executed on the Mobility Conductor, the **upgrademgr** process running on Mobility Conductor sends an upgrade request to **upgrademgr** process running on corresponding managed devices. The managed devices then connect to the image server and download the appropriate image file after verifying the validity of the image file, before upgrading to the downloaded image file. The centralized image upgrade feature is enabled and configured on managed devices only, and supports up to 100 simultaneous image downloads.

Example

```
(host) (config) #show upgrade-profile

Upgrade Profile
-----
Parameter                Value
-----
Server IP address         N/A
Server IPv4/IPv6 address N/A
Username                  N/A
Password                  N/A
Protocol                  tftp
File path                  .
Download AOS Image from MM Enabled
```

The output of this command includes the following information:

Parameter	Description
serverip	The IPv4 address of the image server. This parameter is only used by managed devices running versions prior to ArubaOS 8.2 and accepts only IPv4 address. NOTE: For FTP or SCP protocol, specify the username and password.
serveraddr	The IPv4 or IPv6 address of the image server. This parameter is only used by managed devices running ArubaOS 8.2. NOTE: For FTP or SCP protocol, specify the username and

Parameter	Description
	password.
Username	If the <code>protocol</code> parameter is set to FTP or SCP , this parameter displays the user name that ArubaOS uses to connect to the image server.
Password	If the <code>protocol</code> parameter is set to FTP or SCP , this parameter displays the password that ArubaOS will use to connect to the image server.
Protocol	Specify the protocol used to send the software to the managed device. <ul style="list-style-type: none"> ▪ TFTP ▪ FTP ▪ SCP
File path	File path to the location on the image server where the image file(s) reside.
Download AOS Image from MM	If enabled, the flash storage on the Mobility Conductor is used as a file server for live upgrade and this locally stored image will be downloaded by the managed devices using HTTP protocol.

Related Commands

Command	Description
upgrade-profile	This command is used to configure the upgrade profile.

Command History

Release	Modification
ArubaOS 8.8.0.0	The <code>Download AOS Image from MM</code> parameter was added.
ArubaOS 8.2.0.0	The <code>serveraddr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Available in Enable and Config modes on Mobility Conductor and managed devices.

show uplink

```
show uplink
  cellular {config | connection-logs | details | mbn-profiles | signal}
  debug
  stats
  wired config
```

Description

Displays uplink manager configuration details.

Parameter	Description
cellular	Displays the cellular uplink configuration information.
config	Displays the passive cellular uplink configuration information.
connection-logs	Displays the cellular uplink connection logs.
details	Displays the internal cellular module details.
mbn-profiles	Displays the list of mobile broadband network profiles.
signal	Displays the cellular uplink signal information.
debug	Displays the uplink management debug information.
stats	Displays the statistical information on the designated uplink.
wired	Display the wired uplink information.
config	Displays the passive wired uplink configuration information.

Example

The output of this command displays the managed device uplink status . For a managed device, the health status of these uplink connections is also displayed in the **Status** section of the **Dashboard>WAN** page of the managed device WebUI.

```
(host) #show uplink

Uplink Manager: Disabled
Uplink Health-check: Disabled IP: 0.0.0.0
Uplink Management Table
-----
```

Uplink Type	Properties	Uplink-id	State	Gateway	Reachability	WAN Type
-----	-----	-----	-----	-----	-----	-----

Related Commands

Command	Description
ip probe default	This command configures WAN health-check ping-probes for measuring WAN availability and latency on managed device uplinks.
uplink	Manage and configure the uplink network connection.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Enable and Config mode on Mobility Conductor and managed devices.

show usb

```
show usb
  cellular
  ports [<address>]
  test <address>
  usb-modeswitch
  verbose
```

Description

Display detailed USB device information on a stand-alone controller or managed device. This command should be executed from the managed device only.

Parameter	Description
cellular	Enter the keyword cellular to display cellular devices.
ports	Enter the keyword ports to display detailed TTY port information such as signal strength.
test	Enter the keyword test to test the USB TTY ports. NOTE: Testing an invalid modem port may cause the stand-alone controller or managed device to "hang". To resolve this, unplug and re-plug the modem.
usb-modeswitch	USB mode switch utility log.
verbose	Enter the keyword verbose to display detailed USB information including serial number and USB type.

Examples

The USB Device table, in the example below, displays the USB port is in the 'Device Ready' state, meaning that the port has passed the diagnostic test and is ready to send and receive data.

```
(host-md) #show usb

USB Device Table
-----
Address  Product      Vendor  ProdID  Serial          Type
Profile  State

show user

```
show user
  ap-group <ap-group>
  ap-name <ap-name>
  authentication-method dot1x|mac|opensystem|psk|stateful-dot1x|via-vpn|vpn|web
  bssid <A:B:C:D:E:F>
  devtype <device>
  essid <STRING>
  internal
  ip <A.B.C.D> [log]
  location b.f.l
  mac <A:B:C:D:E:F> [log]
  mobile {[bindings][visitors]}
  name <STRING>
  phy-type {[a]|[b]}
  role <STRING>
  rows <NUMBER> <NUMBER>
```

Description

Displays detailed information about user in terms of AP group, authentication method, role and so on. Use the `show user` command to show detailed user statistics and roles.

Parameter	Description
ap-group <ap-group>	Filter the output of this command by showing users connected to APs that belong to the specified AP group.
ap-name <ap-name>	Filter the output of this command by showing users connected to an AP with the specified AP name.
authentication-method	Filter the output of this command by the authentication method used for the device:
dot1x	Show data for devices using 802.1X authentication.
mac	Show data for devices using MAC authentication.
opensystem	Show data for devices using open (no) authentication.
psk	Show data for devices that do not use authentication but use a pre-shared key for encryption.
stateful-dot1x	Show data for devices using stateful 802.1X authentication.
via-vpn	Show data for devices that authenticate using Aruba VIA.
vpn	Show data for devices using VPN authentication.

Parameter	Description
web	Show data for devices using captive portal authentication.
bssid <A:B:C:D:E:F>	Show user data for a specific device BSSID.
devtype <device>	Show output for a specified device type, if identified. If the device name includes spaces, you must enclose it in quotation marks.
ssid <STRING>	Show user data for a specific ESSID. If the ESSID includes spaces, you must enclose it in quotation marks.
internal	Display internal user entries only. Include the rows options to filter the output of this command by specifying the number of rows from the end of the output and the total number of rows to display/
ip <A.B.C.D>	Show user data for a specific IP address .
log	If per-user logging is enabled using the aaa log command, include the optional <code>log</code> parameter to display authentication log files for a user with the specified MAC address.
mac <A:B:C:D:E:F>	Show user data for a specific MAC address
log	If per-user logging is enabled using the aaa log command, include the optional <code>log</code> parameter to display authentication log files for a user with the specified MAC address.
mobile	Filter the output of this command to show data for Mobile users.
bindings	Show data for users that have moved away from their home network.
visitors	Show data for mobility users that are visiting the network.
name <STRING>	User's name.
phy-type	801.11 type
a	Matches PHY type a.
g	Matches PHY type b or g.
role <STRING>	User role such as employee, visitor and so on.
rows <NUMBER> <NUMBER>	Filter the output of the show user command by specifying the number of rows from the end of the output and the total number of rows to display/

Example

```

(host) #show user
Users
-----
IP           MAC           Name   Role   Age(d:h:m)  Auth  VPN link  AP name
Roaming     Essid/Bssid/Phy  Profile Forward mode  Type  Host Name
-----
-----
User Entries: 0/0
Curr/Cum Alloc:0/0 Free:0/0 Dyn:0 AllocErr:0 FreeErr:0

```

  unique
  verbose
```

Description

Displays detailed information about the controller's connection to a user device, in regards to mobility state and statistics, authentication statistics, VLAN assignment method, AP datapath tunnel info, radius accounting statistics, user name, user-role derivation method, datapath session flow entries, and 802.11 association state and statistics. The `show user` command allows you to filter specific information by parameter. Use the `show user-table` command to show detailed user statistics which includes the entire output of the user-table, mobility state and statics, authentication statistics, VLAN assignment method, AP datapath tunnel information, radius accounting statistics, user-role derivation method, datapath session flow entries, and 802.11 association state and statistics.

Parameter	Description
<code>ap-group <ap-group></code>	Filter the output of this command by showing users connected to APs that belong to the specified AP group.
<code>ap-name <ap-name></code>	Filter the output of this command by showing users connected to an AP with the specified AP name.
<code>authentication-method</code>	Filter the output of this command by the authentication method used for the device:
<code>dot1x</code>	Show data for devices using 802.1X authentication.

Parameter	Description
mac	Show data for devices using MAC authentication.
opensystem	Show data for devices using open (no) authentication.
psk	Show data for devices that do not use authentication but use a pre-shared key for encryption.
stateful-dot1x	Show data for devices using stateful 802.1X authentication.
via-vpn	Show data for devices that authenticate using Aruba VIA.
vpn	Show data for devices using VPN authentication.
web	Show data for devices using captive portal authentication.
bssid <A:B:C:D:E:F>	Show user data for a specific device BSSID.
debug	Show all user data for debugging purposes.
devtype <device>	Show output for a specified device type, if identified. If the device name includes spaces, you must enclose it in quotation marks.
ssid <STRING>	Show user data for a specific SSID. If the SSID includes spaces, you must enclose it in quotation marks.
internal	Display internal user entries only. Include the rows options to filter the output of this command by specifying the number of rows from the end of the output and the total number of rows to display/
ip <A.B.C.D>	Show user data for a specific IP address .
log	If per-user logging is enabled using the aaa log command, include the optional <code>log</code> parameter to display authentication log files for a user with the specified MAC address.
detail	Show detailed user data for a specific IP address including role-derivation.
mac <A:B:C:D:E:F>	Show user data for a specific MAC address
log	If per-user logging is enabled using the aaa log command, include the optional <code>log</code> parameter to display authentication log files for a user with the specified MAC address.
mobile	Filter the output of this command to show data for Mobile users.
bindings	Show data for users that have moved away from their home network.

Parameter	Description
visitors	Show data for mobility users that are visiting the network.
name <STRING>	User's name.
phy-type	801.11 type
a	Matches PHY type a.
g	Matches PHY type b or g.
role <STRING>	User role such as employee, visitor and so on.
rows <NUMBER> <NUMBER>	Filter the output of the show user command by specifying the number of rows from the end of the output and the total number of rows to display/
standby	User standby entries
ipv4	User standby entries for the IPv4 address specified.
ipv6	User standby entries for the IPv6 address specified.
log	Debug log of the specified user.
mac	User standby entires for the MAC address specified.
station	For internal use only.
summary	Shows the authentication and encryption type used by wired or wireless clients.
unique	Displays only information for users with a valid IP address.
verbose	Displays all information about the user table.

Examples

This example displays users currently in the **employee** role. The output of this command is split into two tables in this document, however it appears in one table in the CLI.

```
(host) [mynode] (config) show user-table role employee
Users
-----
      IP                MAC                Name                Role                Age (d:h:m)
Auth   VPN link   AP name
-----
-----
192.168.160.1  00:23:6c:80:3d:bc  madison1            employee            01:05:50

The `role-how` and `vlan-how` parameters in the output of this command display a code that corresponds to the following values:

Role Derivation Code	Description
1	AAA profile default role
2	Role derived from user rules
3	Role derived from UDR
4	Default role for authentication type
5	Role derived from server rules
6	Aruba vendor-specific attribute (VSA)
7	Dot1X profile role
8	Dot1X server derived role
9	Dot1X role derived from Aruba VSA
10	Dot1X role derived from ClearPass Policy Manager VSA
11	Role derived from DHCP option
12	Change of authorization role
13	Forced role set by ESI
14	Role derived from mobility
15	Role assigned by external/internal captive portal
16	Role assigned by SIP
17	SDR derived role during L3 authentication
18	VSA derived role during L3 authentication

Role Derivation Code	Description
19	ClearPass Policy Manager VSA derived role during L3 authentication
20	Authentication type VPN role (VIA, VPN, or Transport VPN)
21	Authentication type role (BTLM, Kerb, GIS, or so on)
22	System assigned AP role

VLAN Derivation Code	Description
1	Default VLAN
2	Initial role contained
3	User rule role contained
4	Matched user rule
5	DHCP Option 77 role contained
6	Matched DHCP Option 77
7	MBA role contained
8	MBA server rule role contained
9	MBA server rule
10	MBA Aruba VSA role contained
11	MBA Aruba VSA
12	MBA MSFT attributes
13	User Dot1X role contained
14	Dot1X server rule role contained
15	Dot1X server rule
16	Dot1X Aruba VSA role contained
17	Dot1X Aruba VSA
18	Dot1X MSFT attributes
19	VLAN from pmk-cache

VLAN Derivation Code	Description
20	DHCP options user rule role contained
21	DHCP options user rule
30	Adaptive DHCP VLAN

show util_proc

```
show util_proc guest-email counters
```

Description

Show counters for the guest email process. As part of guest provisioning, the guest access email feature allows you to define the SMTP port and server that processes guest provisioning email. This server sends email to the guest or the sponsor when a guest user manually sends email from the Guest Provisioning page, or when a user creates a guest account.

Example

The output of this command shows the numbers of guest emails received, sent and dropped since the controller was last reset

```
(host) #show util_proc guest-email counters

Guest Email Counters
-----
Name                Value
----                -
Email Received      14
Email Sent           3
Email Dropped       0.
```

show valid-network-oui-profile

show valid-network-oui-profile

Description

This command displays the Valid Equipment OUI Profile table. If you use the valid-networkoui-profile to add a new OUI to the controller, use the show valid-network-oui-profile command to see a list of current OUIs.

Example

```
(Host) (config) #show valid-network-oui-profile

Valid Equipment OUI profile
-----
Parameter  Value
-----
OUI         00:1A:1E
```

Related Commands

show version

```
show version
```

Description

Shows the system software version.

Example

```
(host) #show version
Aruba Operating System Software.
      ArubaOS (MODEL: Dell Networking W-650 Controller-US),
Version 6.1.0.0
Website: http://www.dell.com
Copyright (c) 2002-2011, Aruba Networks, Inc.
Compiled on 2011-04-28 at 00:18:36 PDT (build 28106) by p4build

ROM: System Bootstrap, Version CPBoot 1.0.0.0 (build 23274)
Built: 2010-01-19 11:11:41
Built by: p4build@re_client_23274

Switch uptime is 1 days 6 hours 2 minutes 4 seconds
Reboot Cause: User reboot.
Supervisor Card
Processor XLS 408 (revision B1) with 890M bytes of memory.
32K bytes of non-volatile configuration memory.
256M bytes of Supervisor Card System flash (model=NAND 256MB)
```

The output of this command includes the following information

Parameter	Description
Model	controller model type.
Version	Version of ArubaOS software.
ROM	System bootstrap version.
Switch Uptime	Switch uptime (time elapsed since the last controller reset.
Reboot Cause	Reason the controller was last rebooted.
Supervisor Card	Details for the controller's internal supervisor card.

Command History

show via

```
show via
  version
  websessions
  lastlogin
```

Description

Displays the VIA version and web session details.

Parameter	Description
version	Displays the version of VIA client available on the controller.
websessions	Displays the list of users connected to the VIA controller using the VIA client.
lastlogin	Displays the time that the VIA user last logged in.

Example

The following example displays the version of VIA client available on the controller.

```
(host) # show via version(host) (VIA Client WLAN Profile "example") #show
via version
Default VIA Installer:
-----
<aruba>
  <via>
    <platform>win32</platform>
    <version>1.0.0.23373</version>
  </via>
</aruba>
The following example displays the time that the VIA user last logged in.
(host) [mm] #show via-lastlogin
VIA users login Details
-----
User Name   Last Login Time (GMT)
-----
vpatil123  Wed Jun 20 16:41:19 2018

show vlan mapping

show vlan mapping

Description

This command shows a configured VLAN name, its pool status, assignment type, and the VLAN IDs assigned to the pool. Use this command to show the selected VLAN configuration. The **VLAN Name** column displays the name of the VLAN pool. The **VLAN IDs** column lists the VLANs that are part of the pool.

Parameter	Description
<id>	Identification number for the VLAN. 1-4094 1

Example

```
(Host) [mynode] (config) #show vlan mapping
Vlan Mapping Table
-----
VLAN Name  Assignment Type  VLAN IDs      IP Timeout  Max IP Timeouts Full
Period
-----
-----
-----
-----
-----
a          Even             1001-1002     10          3
30
```

Related Commands

Command	Description
vlan	This command creates a VLAN ID or a range of VLAN IDs on the managed device.
vlan-name	This command creates a named VLAN on the managed device and given an assignment type.

Command History

Release	Modification
ArubaOS 8.7.0.0	The output parameters IP Timeout, Max IP Timeouts and Full Period were introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

show vlan status

```
show vlan status <id>
```

Description

This command shows the current status of all VLANs on the controller. Use this command to show the status of VLANs on the controller. The **VLAN ID** column displays the VLAN ID name or number. The **IP Address** column provides the VLAN's IP address. The **Adminstate** column indicates if the VLAN is enabled or disabled. The **Operstate** column indicates if the VLAN is currently up and running. The **PortCount** column shows how many ports are associated with the VLAN. The **Nat Inside** column displays whether source Nat is enabled for the VLAN interface. If Nat is enabled, all the traffic passing through this VLAN interface is the source natted to the outgoing interface's IP address.

Example

```
(host) #show vlan status

Vlan Status
-----
VlanId  IPAddress                               Adminstate  Operstate  PortCount  Nat
Inside  Mode    Ports                               -----  -----  -----  -----
-----  -----  -----
1        unassigned/unassigned                 Enabled     Up          9

show vlan id

show vlan <id>

Description

This command shows a configured VLAN interface number, description and associated ports. Issue this command to show the selected VLAN configuration. The **VLAN** column lists the VLAN ID. The **Description** column provides the VLAN name or number and the **Ports** column shows the VLAN's associated ports. The **AAA Profile column** shows if a wired AAA profile has been assigned to a VLAN, enabling role-based access for wired clients connected to an untrusted VLAN or port on the controller.

Parameter	Description
<id>	Identification number for the VLAN. 1-4094 1

```
(host) #show vlan 102
VLAN CONFIGURATION
-----
VLAN  Description  Ports      AAA Profile  Option-82
----  -

show vlan-bwcontract-explist

show vlan-bwcontract-explist [internal]

Description

Show entries in the VLAN bandwidth contracts MAC exception lists.

Parameter	Description
internal	Include the optional <code>internal</code> parameter to display the MAC addresses in the internal, preconfigured VLAN bandwidth contracts MAC exception list.

Example

The following command displays the MAC addresses in the internal MAC exception list.

```
(host) (config) #show vlan-bwcontract-explist internal

VLAN BW Contracts Internal MAC Exception List
-----
MAC address
-----
01:80:C2:00:00:00
01:00:0C:CC:CC:CD
01:80:C2:00:00:02
01:00:5E:00:82:11
```

Related Commands

Command	Description
vlan-bwcontract-explist	This command is used to add entries to or remove entries from the MAC exception list for bandwidth contracts on broadcast or multicast traffic.

show vpdn l2tp

```
show vpdn l2tp
  configuration
  local pool <pool_name>
```

Description

Displays the VPN L2TP state.

Parameter	Description
configuration	Show L2TP configuration.
local pool <pool_name>	Show l2tp local IP pool.

Example

The output of this command shows the L2TP tunnel configuration.

```
(host) # show vpdn l2tp configuration

Enabled
Hello timeout: 30 seconds
DNS primary server: 10.16.15.1
DNS secondary server: 10.16.14.1
WINS primary server: 0.0.0.0
WINS secondary server: 0.0.0.0
PPP client authentication methods:
  PAP
IP LOCAL POOLS:
  vpnpool: 10.16.15.150 - 10.16.15.160
```

show vrrp

```
show vrrp {{<vrid>[statistics]}|ipv6<vrid>|stats[all]}|stats[all]|summary}
```

Description

Displays the list of all VRRP configuration on the managed device. To view a specific VRRP configuration, specify the VRID number.

Parameter	Description
<vrid>	Displays the Virtual Router Id. 1-255
ipv6	Display VRRP information for IPv6 address.
stats	Displays the operational statistics of the VRRP.
summary	Displays the number of vrrp instances for IPv4 and IPv6.

Example

The output of the following command shows the VRRP IPv4 instance with vrid 1.

```
(host) [mynode] #show vrrp
Virtual Router 1:
Description
Admin State UP, VR State BACKUP
IP Address 0.0.0.0, MAC Address 00:00:5e:00:01:01, vlan 99
Priority 100, Advertisement 1 sec, Preemption Disable Delay 0
Hold time 45 sec
Auth type NONE *****
tracking is not enabled
```

The output of the following command shows the statistics for IPv4 vrrp instance with vrid 10.

```
(host) [mynode] # show vrrp 10 statistics
Virtual Router 10:
Admin State UP, VR State MASTER
Advertisements:

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

show web-cc

```
show web-cc
  categories
  reputation
  md
    stats
  mm
    stats
  stats
  status
  global-bandwidth-contract all|{web-cc-category <category>}|{web-cc-reputation
<reputation>}
```

Description

Displays information about web content (web-cc) classification settings, category and reputation types, classification statistics and bandwidth contracts. The web content classification feature classifies all (HTTP/HTTPS) web traffic on the network. The output of the `show web-cc` command displays information about Webroot classification categories and risk reputation levels, bandwidth contracts, and the web content classification cache and database.

Parameter	Description
categories	Display the category index number and the category name for each category type.
md stats	Display web content classification table statistics for the managed device. This command must be issued on the managed device.
mm stats	Display web content classification table statistics for Mobility Conductor.
reputation	Display the different reputation levels, and the range of reputation scores associated with each level.
stats	Display counters for web content traffic and web content classification table statistics
status	Display information about the current operational status of the web content classification feature.
global-bandwidth-contract	Display settings for global bandwidth contracts assigned to web content classification category types and reputation levels.
all	Show all bandwidth contracts

Parameter	Description
web-cc-category <category>	Display information for the specified web-cc category bandwidth contract.
web-cc-reputation <reputation>	Display information for the specified web-cc reputation bandwidth contract.

Examples

To see if the WebCC feature is able to send queries from Mobility Conductor to the WebRoot server in the cloud, issue the command `show web-cc status`.

```
(host)[mynode](config) #show web-cc status
Web Content Classification Status
-----
Service Status
-----
Web Content Classification enabled :    Yes
DNS/Name Server configured :          Yes
URL Cloud lookup server reachable :    Yes
Cloud lookup/update available :        Yes
Webroot Server Connection Type :      ipv6
Mode:                                  MM
```

The following command shows the global bandwidth contracts applied to upstream and downstream traffic matching the **music** content category.

```
(host)[mynode](config) #show web-cc global-bandwidth-contract web-cc-
category music
Web-cc Global Bandwidth Contract
-----
Web-cc Category/Reputation  Direction  Rate (bits/second)  Contract  Id
-----
web-cc-category music      Upstream    55000000            music-2126  2
web-cc-category music      Downstream  20000000            music-745c  1
```

The output of the `show web-cc` command varies, depending upon the parameters specified. The following table describes the information displayed in the output of this command when that parameter is included.

Parameter	Description
categories	Include this parameter to display the following information categories in the command output: <ul style="list-style-type: none"> ▪ Name: names of the available web content classification categories

Parameter	Description
	<ul style="list-style-type: none"> ▪ Web Category ID: ID number associated with a category name
reputation	<p>Include this parameter to display the following information categories in the command output:</p> <ul style="list-style-type: none"> ▪ RiskLevel: names of the available web content classification risk levels ▪ Score: Range of risk scores associated with a risk level
Stats	<p>Include this parameter to display the following information categories in the command output:</p> <ul style="list-style-type: none"> ▪ URL miss from sos: number of times a URL was not found in the internal web content classification cache. ▪ Database hit: number of times a URL was not found in the internal web content classification cache, but was found by the local web content classification database. ▪ Cloud lookup: number of times a URL was not found by the local web content classification database, and was sent to the cloud for identification. ▪ Cloud response: number of times the cloud responded to a cloud lookup request. ▪ RTU updates: Number of times that the internal web content classification cache was updated ▪ DB Entries: Maximum number of entries allowed in the local web content classification database. This value varies by controller type.
Status	<p>Include this parameter to display the following information categories in the command output:</p> <ul style="list-style-type: none"> ▪ Web Content Classification enabled: Displays if the web content classification feature is enabled or disabled. ▪ DNS/Name Server configured: Displays if DNS is configured on the controller. The web content classification feature uses DNS to identify the URL cloud server, so DNS must be configured on the controller for this feature to work. ▪ Cloud lookup/update available: A status of Yes indicates that license pool for that configuration node has a sufficient number of unexpired Web Content Classification licenses. A status of No indicates that licenses have expired, or that there are not enough licenses for the managed devices in that pool. ▪ URL Cloud lookup server reachable: Indicates if the controller is able to contact the URL cloud server.

Parameter	Description
	<ul style="list-style-type: none"> ▪ Webroot Server Connection Type: Displays if the connection to the Webroot server to look-up or download the URL database is by using IPv4 or IPv6 addresses. ▪ Mode: Indicates operational mode for the WebCC feature. If the managed device is in centralized mode, the Mobility Conductor (MM) contacts the WebRoot server for URL queries. If the managed device is in distributed mode, the managed device contacts the WebRoot server directly.
global-bandwidth-contract	<p>Include this parameter to display the following information categories in the command output:</p> <ul style="list-style-type: none"> ▪ Web-cc Category/Reputation: Name of the web content classification category or reputation level. ▪ Direction: indicates whether the contract applies to upstream or downstream traffic. ▪ Rate (bits/second) : bandwidth contract rate, in bits/second. ▪ Contract: unique name assigned to the web-cc global bandwidth contract. ▪ Id: identification number assigned to the web-cc global bandwidth contract.

The following output displays the current operational status of web content classification feature when the managed device is in the default centralized WebCC mode or in distributed mode:

```

MD : Webcc mode: Centralized
-----
(Aruba7210) #show web-cc status

Web Content Classification Status
-----
Service                               Status
-----
Web Content Classification enabled :   Yes
DNS/Name Server configured :          Yes
URL Cloud lookup server reachable :    Yes
Cloud lookup/update available :       Yes
Webroot Server Connection Type :      ipv6
Mode :                                 MD - Centralized
MM IP address :                        10.15.60.251

MD : Webcc mode: Distributed
-----
(Aruba7210) #show web-cc status

Web Content Classification Status

```

```

-----
Service                               Status

Command History

Release	Modification
ArubaOS 8.4.0.0	The Webroot Server Connection Type field was added to the output of the <code>show webcc-status</code> command.
ArubaOS 8.2.0.0	The Mode and Cloud lookup/update available fields were added to the output of the <code>show webcc-status</code> command.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	WebCC license	Enable and Config mode on Mobility Conductor.

show web-proxy

show web-proxy

Description

Displays information about the port and server configured for the web-proxy.

Example

The following command shows the port configured for the web-proxy server.

```
(host) [mynode] #show web-proxy
Server: exampleproxy.com
port: 8080
```

Related Commands

Command	Description

show web-server

```
show web-server
  profile
  statistics
```

Description

Displays the configuration and statistics of the controller web server.

Parameter	Description
profile	Displays the web server configuration profile.
statistics	Displays the web server statistics. This command helps to troubleshoot Captive Portal scale issues.

Example

The output of this command shows the web-server configuration.

```
(host) [mynode]# show web-server profile

Web Server Configuration
-----
Parameter                               Value
Set
-----
-
Cipher Suite Strength                    high
SSL/TLS Protocol Config                  tlsv1.2

(host) #show web-server statistics

Web Server Statistics:
-----
Current Request Rate:          1 Req/Sec
Current Traffic Rate:          0 KB/Sec
Busy Connection Slots:         1
Available Connection Slots:    24
Total Requests Since Up Time:  16854
Total Traffic Since Up Time:   199580 KB
Avg. Request Rate Since Up Time: 0 Req/Sec
Avg. Traffic Rate Since Up Time: 321 Bytes/Sec
Server Scoreboard _____W_____

Scoreboard Key: _ - Waiting for Connection, s - Starting up
                R - Reading Request, W - Sending Reply
                K - Keepalive, D - DNS Lookup
                C - Closing connection, L - Logging
                G - Gracefully finishing, I - Idle cleanup of worker
                . - Open slot with no current process

```

The output of the `show web-server statistics` command includes the following parameters.

Parameter	Description
Current Request Rate	HTTP/HTTPS request rate measured immediately within the last one second.
Current Traffic Rate	HTTP/HTTPS data transfer rate measured immediately within the last one second.
Busy Connection Slots	Number of simultaneous HTTP/HTTPS sessions currently being served. Each session occupy one slot from the total available slot configured under the web-max-clients < web-max-client > parameter.
Available Connection Slots	Number of simultaneous HTTP/HTTPS sessions which can be served more than what is being served currently.
Total Requests Since Up Time	Total number of HTTP/HTTPS requests received by the web server since the server was up.
Total Traffic Since Up Time	Total number of HTTP/HTTPS traffic handled by the web server since the server was up.
Avg. Request Rate Since Up Time	Lifetime average of HTTP/HTTPS request rate. This is calculated by dividing the total number of requests received with the web server up-time.
Avg. Traffic Rate Since Up Time	Lifetime average of HTTP/HTTPS traffic rate. This is calculated by dividing the total of HTTP/HTTPS traffic with the web server up-time.
Server Scoreboard	Displays information of each worker thread of web server.

show websocket

```
show websocket
  clearpass
  debug
  state
  statistics
```

Description

Displays the ClearPass WebSocket configuration.

Parameter	Description
clearpass	Shows the ClearPass WebSocket profile.
debug	Shows the WebSocket interface debug information.
state	Shows the WebSocket connection state.
statistics	Shows the WebSocket Interface statistics.

Example

The output of the following command displays the ClearPass WebSocket profile.

```
(host) [mynode] #show websocket clearpass
ClearPass WebSocket Profile
-----
Parameter                               Value
-----
ClearPass WebSocket Interface           Enabled
Primary ClearPass Insight Server        10.4.174.104:443 apiadmin/*****
Secondary ClearPass Insight Server      10.4.174.105:443 apiadmin/*****
The output of the following command displays the WebSocket interface debug
information.
(host) [mynode] #show websocket debug clearpass
ClearPass WebSocket Interface Debug Information
-----
#Active-DevId-Table  #Working-Queue
-----
2                    1
```

The output of the following command displays the current connection state of the ClearPass WebSocket interface that is configured.

```
(host) [mynode] #show websocket state clearpass
```

```

ClearPass Web-Socket Connection State [Interface: Enabled]
-----
Server                               State
-----
Primary:   SECIRTY67.ACMECOMPANY.COM:443  DOWN
Secondary: 10.17.5.210:443                UP[08/22/16 13:38:50]Established

```

The output of this command includes the following parameters.

Parameter	Description
Server	Displays the primary and secondary ClearPass Insight server.
State	Displays the state of the primary and secondary ClearPass Insight server, which is either UP or DOWN.

The output of the following command displays the current statistics of ClearPass WebSocket interface.

```

(host) [mynode] #show websocket statistics clearpass

ClearPass WebSocket Interface Statistics Summary
-----
DevId Replayed  DevId Created  DevId Deleted  SUB Item Sent  SUB Msg Sent
UNSUB Item Sent  UNSUB Msg Sent  PUB Item Received  PUB Item Posted
-----
0                10             0               10             1              0
                0              0               0

```

The output of this command includes the following parameters.

Parameter	Description
DevId Replayed	Counter to track the number of device Ids replayed.
DevId Created	Counter to track the number of device Ids created.
DevId Deleted	Counter to track the number of device Ids deleted.
SUB Item Sent	When an interface is established, the existing device Ids are re-played and sent as sub items to ClearPass.
SUB Msg Sent	Counter to track the sub items that are consolidated and sent to ClearPass as sub messages.

Parameter	Description
UNSUB Item Sent	Counter to track the sub items sent to ClearPass, when ever a device Id is deleted.
UNSUB Msg Sent	Counter to track the deleted sub items consolidated as a sub message and sent to ClearPass.
PUB Item Received	When a subscribed profile for a specific station is updated in the ClearPass Insight server, a PUB message with the station's device profile information is sent back to the controller through the WebSocket connection. This event is mapped to the ArubaOS device type data.
PUB Item Posted	Counter to track the items successfully posted.

show whitelist-db cpsec/show allowlist-db cpsec

```
show whitelist-db cpsec/show allowlist-db cpsec
  ap-group <ap_group>
  ap-name <ap_name>
  cert-type {factory-cert|switch-cert}
  mac-address <name>
  page <num>
  page-size <page-size>
  search-by
  sort-by
  sort-direction {ascending | descending}
  start <offset>
  state {approved-ready-for-cert|certified-factory-cert|unapproved-factory-
cert|unapproved-no-cert}
```

Description

Displays the campus AP whitelist/allowlist for campus APs using the control plane security feature. To view information for a single AP, use the command `show whitelist-db cpsec mac-address <mac-address>/ show allowlist-db cpsec mac-address <mac-address>`. If your deployment includes both Mobility Conductor and managed devices, then the campus AP whitelist/allowlist on every managed device contains an entry for every secure AP on the network, regardless of the managed device to which it is connected.

Parameter	Description
<code>ap-group <ap_group></code>	Specify the AP-Group name.
<code>ap-name <ap_name></code>	Specify the AP name.
<code>cert-type</code> <code>factory-cert switch-cert</code>	<ul style="list-style-type: none">▪ factory-cert: Use this parameter if AP is using a factory certificate.▪ switch-cert: Use this parameter if AP is using a certificate signed by the switch.
<code>mac-address <name></code>	MAC address of the campus AP you want to enter into the CPsec allowlist database.
<code>page <num></code>	ArubaOS CLI displays 50 whitelist/allowlist database entries per page. Filter the output of this command by displaying information starting at the specified page number.
<code>page-size <page-size></code>	Display number of records per page. The default value is 50 and a maximum of 500 records can be displayed per page.

Parameter	Description
search-by <searchstr>	Specify the string to search for.
sort-by	Specify the column by which the list is to be sorted.
sort-direction {ascending descending}	Sort the list in ascending or descending order.
start <offset>	Start displaying the table at the specified record in the database
state	Sort by one of the following AP states: <ul style="list-style-type: none"> ▪ approved-ready-for-cert: AP in Approved state and is ready to receive a certificate. ▪ certified-factory-cert: AP in Certified state and has a factory certificate. ▪ unapproved-factory-cert: AP in Unapproved state and has a factory certificate. ▪ unapproved-no-cert: AP in Unapproved state and has no or unknown certificate.

Example

The output of the following command shows the campus AP allowlist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) #show whitelist-db cpsec mac-address 00:16:CF:AF:3E:E1 /show
allowlist-db cpsec mac-address 00:16:CF:AF:3E:E1

Control-Plane Security whitelist/allowlist-entry Details
-----
MAC-Address      AP-Group      AP-Name      Enable      State
-----
00:16:CF:AF:3E:E1  employee      ap-office1    Enabled     cert-cont-cert

Cert-Type      Description  Revoke Text  Last Updated
-----
switch-cert                                Fri Oct 16 01:21:09 2009

Whitelist/Allowlist Entries: 1
```

The output of this command includes the following parameters:

Parameter	Description
MAC-Address	MAC address of the campus AP.

Parameter	Description
Enable	Shows whether the campus AP has been enabled or disabled.
State	Shows the current state of the campus AP. <ul style="list-style-type: none"> ▪ unapproved-no-cert: AP has no certificate and is not approved. ▪ unapproved-factory-cert: AP has a preinstalled certificate that was not approved. ▪ approved-ready-for-cert: AP is valid, but is waiting to receive a certificate. ▪ certified-factory-cert: AP has an approved factory-installed certificate ▪ certified-controller-cert: AP has an approved certificate from the managed device. ▪ certified-hold-factory-cert: An AP is put in this state when the managed device thinks the AP has been certified with a factory certificate yet the AP requests to be certified again. Since this is not a normal condition, the AP will not be reapproved as a secure AP until a network administrator manually changes the status of the AP to verify that it is not compromised. ▪ certified-hold-controller-cert: An AP is put in this state when the managed device thinks the AP has been certified with a managed device certificate yet the AP requests to be certified again. Since this is not a normal condition, the AP will not be reapproved as a secure AP until a network administrator manually changes the status of the AP to verify that it is not compromised.
Cert-Type	Type of certificate used by the AP. <ul style="list-style-type: none"> ▪ switch-cert: AP received a certificate from the managed device ▪ factory-cert: AP has a factory-installed certificate
Description	If you included an optional description when you added the AP to the campus AP whitelist/allowlist, that description will appear here.
Revoke Text	If you included an optional revoke description when you manually revoked the AP, that description will appear here.
Last Updated	Date and time that the AP record was last updated in the database.

Related Commands

Command	Description
whitelist-db cpsec add / allowlist-db cpsec add	Configure the campus AP whitelist/allowlist for the control plane security feature.

All platforms	Base operating system.	Enable and Config mode on Mobility Conductor.

show whitelist-db cpsec-seq/show allowlist-db cpsec-seq

show whitelist-db cpsec-seq/show allowlist-db cpsec-seq

Description

Display the current sequence number for the Mobility Conductor or managed device whitelists/allowlists. The current sequence number in the **Sequence Number Details** table shows the number of changes to the campus AP whitelist/allowlist made on this managed device. Each managed device compares its campus AP whitelist/allowlist against whitelists/allowlists on other managed devices every two minutes. If a managed device detects a difference, it will send its changes to the other managed devices on the network. If all other managed devices on the network have successfully received and acknowledged all whitelist/allowlist changes made on this managed device, every entry in the **sequence number** column in the managed device whitelist/allowlist will have the same value as the number displayed in the **Sequence Number Details** table. If a managed device in the Mobility Conductor or managed device whitelist/allowlist has a lower sequence number, that managed device may still be waiting to complete its update, or its update acknowledgment may not have yet been received.

Example

The output of the first command below shows that the campus AP whitelist/allowlist has been updated 3 times on Mobility Conductor. The second command shows the managed device list on Mobility Conductor, and verifies that both managed devices have received and acknowledged all three of these changes.

```
(host) #show whitelist/allowlist-db cpsec-seq
Sequence Number Details
-----
Table Name          Current Seq Number
-----
cpsec_whitelist/allowlist  3

Whitelist Entries: 97

(host) # show whitelist/allowlist-db cpsec-local-list
Registered Local controller Details
-----
MAC-Address          IP-Address  Sequence Number  Remote Sequence Number  NULL
Update Count
-----
00:0b:86:51:a5:4c  10.3.53.2   3                1
00:A0:C9:14:C8:29  10.3.53.4   3                0

Whitelist/allowlist Entries: 2
```

show whitelist-db rap / show allowlist-db rap

```
show whitelist-db rap / show allowlist-db rap
  apgroup <ap-group>
  apname <ap-name>
  export-css <filename>
  fullname <full-name>
  long
  mac-address <address>
  page <num>
  page-size <page-size>
  search-by
  sort-by
  sort-direction {ascending | descending}
  start <offset>
```

Description

View detailed information for the remote AP whitelist/allowlist database.

Parameter	Description
apgroup <ap-group>	Display specific AP-entries for this AP-group.
apname <ap-name>	Display specific AP-entry for this AP-name.
export-css	Export the remote AP white list/allowlist to a file in the managed device's /flash/config/ folder. This file can be given to a content security provider to manage the remote AP database.
fullname <full-name>	Display specific AP-entry for this full-name in the RAP whitelist/allowlist database.
long	Display additional debugging information about an entry in the RAP whitelist/allowlist, including when it was last updated, the sequence number for the update, and any flags for the entry.
mac-address <mac-addr>	Display a whitelist/allowlist entry for the specified RAP MAC address.
page	ArubaOS CLI displays 50 whitelist/allowlist database entries per page. Filter the output of this command by displaying information starting at the specified page number.
page-size <page-size>	Display number of records per page. The default value is 50 and a maximum of 500 records can be displayed per page.

Parameter	Description
search-by <searchstr>	Specify the string to search for.
sort-by	Specify the column by which the list is to be sorted.
sort-direction {ascending descending}	Sort the list in ascending or descending order.
start <offset>	Start displaying the table at the specified record in the database

Example

In the example below, the command output has been divided into two tables to fit on a single page of this document. In the CLI, this output would appear in a single, wide table.

```
(host) #show whitelist-db rap / show allowlist-db rap

```

The output of this command includes the following information:

Parameter	Description
Name	MAC address of the remote AP.

Parameter	Description
AP-Group	Name of the AP group to which the remote AP has been assigned.
AP-name	Name of the remote AP. If no name has been specified, this column will display the remote AP's MAC address
Full-name	Text string used to identify the remote AP. This field often describes the AP's user, and corresponds to the User Name field in the RAP whitelist in the WebUI.
Authen-Username	User name of the user who authenticated the remote AP. This parameter holds the user name of the user who authenticated the remote AP. This is related to the zero touch authentication feature, as a user needs to authenticate an AP before it gets its complete configuration. Before the AP is authenticated, it is given a restricted configuration to allow users to perform captive portal authorization via the remote AP's ENET ports to authenticate the remote AP. The username used during captive portal authentication will be stored in this field. This cannot be added manually when creating a local-userdb-ap entry.
Revoke-Text	The command allowlist/whitelist-db rap revoke includes an optional revoke-comment parameter that allows network administrators to explain why the remote AP was revoked. If a remote AP is revoked, and a revoke comment entered, this text appears in the revoke-text column in the <code>show allowlist/whitelist-db rap command</code> . When a local DB entry is reenabled via the command allowlist/whitelist-db rap modify mac-addr mode enable , this field is cleared.
AP_Authenticated	This column indicates the authorization status of the RAP. A RAP can either be Authenticated or Provisioned . Remote APs that <i>do not</i> support certificate-based provisioning will always display a Provisioned status. Remote APs that support certificate-based provisioning can display either a Authenticated or Provisioned status, depending on their configuration and authentication status. <ul style="list-style-type: none"> ■ If the remote AP has a defined AP authorization profile, the remote AP will be in a "Provisioned" state with a limited configuration until it is authenticated. After the remote AP has been authenticated, it will be in an "Authenticated" state. ■ If the remote AP does not have a defined AP authorization profile, the remote AP will be in a "Provisioned" state, but will still receive the full configuration assigned to that AP and its AP group.
Description	A text string used to further identify the remote AP.
Date-Added	Date and time that the AP was added to the local user database
Enabled	This column shows if the entry in the database is enabled or disabled. Database entries can be enabled or disabled using the CLI commands: <pre> allowlist/whitelist-db rap {add modify} mac-address <mac-addr> mode{enable disable} and allowlist/whitelist-db rap revoke mac-address <mac-addr> </pre>

Related Commands

show whitelist-db rap-local-switch-list/show allowlist-db rap-local-switch-list

```
show whitelist-db rap-local-switch-list [mac-address <mac-address>]
```

Description

Displays the remote AP whitelist/allowlist local switch list on Mobility Conductor. When you have remote APs on a network with both master/conductor and managed devices, Mobility Conductor maintains a whitelist/allowlist of managed devices with remote APs. When you change a remote AP whitelist/allowlist on any managed device, that managed device contacts Mobility Conductor to check the local switch whitelist/allowlist, then contacts every other managed device to notify it of the change. This allows a remote AP to move between managed devices and still stay connected to the secure network.

To view information for a single managed device, use the command `show whitelist-db rap-local-switch-list mac-address <mac-address>`. To view a list of all managed devices, use the command `show whitelist-db rap-local-switch-list`.

Parameter	Description
<code>mac-address <mac-address></code>	MAC address of the managed device whose data you want to view.

Example

The following command shows information for all managed devices in the managed device whitelist. The output in the example below has been divided into sections to better fit on the pages of this document. In the ArubaOS CLI, the output appears in a single, long table.

```
(host) #show whitelist-db rap-local-switch-list

```

The output of this command includes the following information:

Parameter	Description
Active	Shows if the managed device is active on the network. <ul style="list-style-type: none"> ▪ 1: Active ▪ 0: Inactive
MAC-Address	MAC address of the managed device.
IP-Address	IP address of the managed device.
Sequence Number	The number of times the managed device in the whitelist/allowlist received and acknowledged a remote AP whitelist/allowlist change from Mobility Conductor. In the example above, both managed devices received and acknowledged three remote AP whitelist/allowlist changes sent from Mobility Conductor.
Remote Sequence Number	The number of times that Mobility Conductor has received and acknowledged a remote AP whitelist/allowlist change from the managed device in the whitelist/allowlist. In the example above, Mobility Conductor received and acknowledged a single remote AP whitelist/allowlist change from the managed device with the MAC address 00:0b:86:51:a5:4c.
Null Update Count	The number of times the managed device has checked its remote AP whitelist/allowlist and found nothing to synchronize with the remote managed device. By default, the managed device compares its remote AP whitelist/allowlist against whitelist/allowlist on other managed devices every minute. If the null update count reaches 5, the managed device will send an "empty sync" heartbeat to the remote managed device to ensure the sequence numbers on both managed devices are the same, then reset the null update count to zero.

Related Commands

show whitelist-db rap-master-switch-list/show allowlist-db rap-local-switch-list

```
show whitelist-db rap-master-switch-list [mac-address <mac-address>]/show  
allowlist-db rap-local-switch-list [mac-address <mac-address>]
```

Description

Displays the remote AP whitelist/allowlist master/conductor switch list on managed devices with remote APs. When your network has both master/conductor and managed devices, each managed device with associated remote APs has a master/conductor switch whitelist/allowlist which contains the IP and MAC addresses of Mobility Conductor. If your network has a redundant Mobility Conductor, then this list will contain more than one entry.

To view information for a single Mobility Conductor, use the command `show whitelist-db rap-master-switch-list mac-address <mac-address>/show allowlist-db rap-local-switch-list mac-address <mac-address>`. To view a list of all Mobility Conductors, use the command `show whitelist-db rap-master-switch-list/show allowlist-db rap-local-switch-list`.

Parameter	Description
mac-address <mac-address>	MAC address of the managed device whose data you want to view.

Example

The following command shows that the managed devices have a single Mobility Conductor with the IP address 192.0.2.143. The output in the example below has been divided into sections to better fit on the pages of this document. In the ArubaOS CLI, the output appears in a single, long table.

```
Active Sequence  MAC-Address          IP-Address          Sequence Number    Remote

show whitelist-db rap-status / show allowlist-db rap-status

show whitelist-db rap-status / show allowlist-db rap-status

Description

Display aggregate status information APs in the remote AP whitelist/allowlist.

Example

The output of the following command shows current status information for all APs in the remote AP whitelist/allowlist:

```
(host) #show whitelist-db rap-status / show allowlist-db rap-status
Entries in whitelist/allowlist database

Total entries:                41
Revoked entries:              1
Marked for deletion entries:  0
```

The output of this command includes

Parameter	Description
Total entries	Total number of entries in the remote AP whitelist/allowlist.
Revoked entries	Number of remote APs whose entries have been revoked.
Marked for deletion entries	Number of remote APs whose entries have been marked for deletion. An entry will not be permanently deleted until all other managed devices on the network acknowledge the deletion.

show wlan 6ghz-rrm-ie-profile

```
show wlan 6ghz-rrm-ie-profile [<profile-name>]
```

Description

Shows a list of all 6GHz RRM IE profiles, or display detailed configuration information for a specific profile. Use this command without the <profile> parameter to display the 6GHz RRM IE profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an 6GHz RRM IE profile.

Examples

The following example shows one 6GHz RRM IE profile configured on the controller.

The **References** column lists the number of other profiles with references to the 6GHz RRM IE profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host)[mynode] #show wlan 6ghz-rrm-ie-profile

RRM IE Profile for 6GHz List
-----
Name       References  Profile Status
-----
default   1
Total:1
```

The following example shows configuration settings defined for the profile **default**:

```
(host)[mynode] #show wlan 6ghz-rrm-ie-profile default

RRM IE Profile for 6GHz "default"

show wlan anyspot-profile

```
show wlan anyspot-profile [<profile-name>]
```

Description

The output of this command displays configuration settings for a WLAN anyspot profile. The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks. Use this command without the <profile> parameter to display the entire anyspot profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an anyspot profile.

Example

The following command displays configuration information for an active (enabled) anyspot profile with two excluded ESSIDs, and one preset ESSID.

```
(host) [mynode] #show wlan anyspot-profile default
Anyspot profile "default"
-----
Parameter                               Value
-----
Enable Anyspot                           true
Exclude ESSID(s) (exact match)           corp_dev_1
Exclude ESSID(s) (exact match)           corp_voip_1
Exclude ESSID(s) (containing string(s))  N/A
Preset ESSID(s)                           corpGuest
```

The output of this command displays the following parameters:

Parameter	Description
enable-anyspot	Indicates if the anyspot feature is enabled or disabled.
exclude-ssid <exclude-ssid>	An anyspot-enabled radio will not respond to client probe requests using an ESSID in the Exclude ESSID lists. ESSIDs from neighboring APs will automatically appear in this list as long as the anyspot-enabled AP can detect that ESSID.

Parameter	Description
<code>exclude-wildcard <exclude-wildcard></code>	An anyspot-enabled radio will not respond to client probe requests using an ESSID that matches a string in the Exclude ESSID (containing string) list .
<code>preset-ssid <preset-ssid></code>	If a client sends a probe request without an ESSID (that is, the probe request is not looking for a specific network) then the anyspot-enabled AP will respond to the probe request with an ESSID from this list.

Related Commands

Command	Description
<code>wlan anyspot-profile</code>	The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.

show wlan bcn-rpt-req-profile

```
show wlan bcn-rpt-req-profile <profile-name>
```

Description

Shows configuration and other information about the parameters for the Beacon Report Request frames. Use this command without the <profile> parameter to display the entire Beacon Report Request profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile. For this profile to take effect, the 802.11K feature needs to be enabled.

Parameter	Description
<profile-name>	Name of a WLAN beacon report request profile.

Example

The following command displays configuration information for the Beacon Report Request frames:

```
(host)(mynode) #show wlan bcn-rpt-req-profile
Beacon Report Request Profile List
-----
Name      References  Profile Status
----      -
default   1

Total:2
(host) #
(host) #show wlan bcn-rpt-req-profile default

Beacon Report Request Profile "default"
-----
Parameter                               Value
-----
Interface                                 1
Regulatory Class                          12
Channel                                   9
Randomization Interval                    100
Measurement Duration                       100
Measurement Mode for Beacon Reports        active-all-ch
Reporting Condition                         2
ESSID Name                                aruba-ap
Reporting Detail                           Disabled
Measurement Duration Mandatory             Disabled
Request Information values                  0/21/22
```

The output of this command includes the following parameters:

Parameter	Description
Interface	Specifies the Radio interface for transmitting the Beacon Report Request frame. It can have a value of either 0 or 1.
Regulatory Class	Specifies the Regulatory Class field in the Beacon Report Request frame.
Channel	Specifies the Channel field in the Beacon Report Request frame.
Randomization Interval	Specifies the Randomization Interval field in the Beacon Report Request frame. The Randomization Interval is used to specify the desired maximum random delay in the measurement start time. It is expressed in units of TUs (Time Units).
Measurement Duration	Specifies the Measurement Duration field in the Beacon Report Request frame. The Measurement Duration is set to the duration of the requested measurement. It is expressed in units of TUs.
Measurement Mode for Beacon Reports	Specifies the mode used for the measurement. The valid measurement modes are: <ul style="list-style-type: none"> ▪ active-all-ch ▪ active-ch-rpt ▪ beacon-table ▪ passive
Reporting Condition	Specifies the value for the "Reporting Condition" field in the Beacon Reporting Information sub-element present in the Beacon Report Request frame.
ESSID Name	Specifies the value for the "SSID" field in the Beacon Report Request frame.
Reporting Detail	Indicates the value for the "Detail" field in the Reporting Detail sub-element present in the Beacon Report Request frame.
Measurement Duration Mandatory	Specifies the "Duration Mandatory" bit of the Measurement Request Mode field of the Beacon Report Request frame.
Request Information values	Indicates the contents of the Request Information IE that could be present in the Beacon Report Request frame. The Request Information IE is present for all Measurement Modes except the 'Beacon Table' mode. It consists of a list of Element IDs that should be included by the client in the response frame.

```

The output of this command includes the following data columns:

Parameter	Description
Advertise 802.11k Capability	Shows if the profile has enabled or disabled the 802.11K feature.
Forcefully disassociate on-hook voice clients	If enabled, the AP may forcefully disassociate clients that reach the maximum CAC peak capacity or call handoff reservation.
Measurement Mode for Beacon Reports	Shows the profile's beacon measurement mode: <ul style="list-style-type: none"> ▪ active: In this mode, the client sends a probe request to the broadcast destination address on all supported channels, sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report. ▪ beacon-table: In this mode, the client measures beacons and returns a report with stored beacon information for any supported channel with the requested SSID and BSSID. The client does not perform any additional measurements. This is the default beacon measurement mode. ▪ passive: In this mode, the client sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.

show wlan dot11r-profile

show wlan dot11r-profile [<profile>]

Description

Shows a list of all 802.11r profiles, or display detailed configuration information for a specific 802.11r profile. Use this command without the <profile> parameter to display the 802.11r profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile>	Name of an 802.11r profile.

Examples

The following example shows that the controller has two configured 802.11r profiles.

The **References** column lists the number of other profiles with references to the 802.11r profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host)[mynode] #show wlan dot11r-profile

802.11r Profile List
-----
Name                References  Profile Status
----                -
default             8
voice-enterprise    1

Total: 2
```

The following example shows configuration settings defined for the profile **default**:

```
(host)[mynode] #show wlan dot11r-profile default
802.11r Profile "default"
-----
Parameter                Value
-----
Advertise 802.11r Capability  Disabled
802.11r Mobility Domain ID   1
802.11r R1 Key Duration     3600
802.11r R1 Key Assignment    dynamic
```

The output of this command includes the following data columns:

Parameter	Description
Advertise 802.11r Capability	Shows if the profile has enabled or disabled the 802.11r feature.
802.11r Mobility Domain ID	Shows the unique ID that identifies the mobility domain.
802.11r R1 Key Duration	Shows the r1 key timeout value in seconds for decrypt-tunnel or bridge mode.
802.11r R1 Key Assignment	Shows if the r1 key assignment is static or dynamic.

show wlan edca-parameters-profile

```
show wlan edca-parameters-profile ap|station [<profile>]
```

Description

Displays an EDCA profile for APs or for clients (stations). EDCA profiles are specific either to APs or clients. Use this command without the <profile> parameter to display a EDCA Parameters profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile>	Name of a EDCA Parameters profile.

Examples

The following example shows that the controller has three EDCA Parameters profiles configured for stations. The **References** column lists the number of other profiles with references to the EDCA Parameters profile, and the **Profile Status** column indicates whether the profile is predefined. (User-defined profiles will not have an entry in the Profile Status column.)

```
(host)[mynode] #show wlan edca-parameters-profile station
EDCA Parameters profile (Station) List
-----
Name           References  Profile Status
----           -
station-corp1  3
station-corp2  1
testprofile    0

Total:3
```

The following example shows configuration settings defined for the profile **station-corp1**:

```
(host)[mynode] #show wlan edca-parameters-profile ap station-corp1
EDCA Parameters
-----
AC           ECWmin  ECWmax  AIFSN  TXOP  ACM
--           -
Best-effort  4       6       3       0     0
Background  4       10      7       0     0
Video       3       4       1       94    0
Voice       2       3       1       47    0
```

The output of this command includes the following data columns:

Parameter	Description
AC	Name of an Access channel queue (Best-effort, Background, Video, or Voice).
ECWmin	The exponential (n) value of the minimum contention window size, as expressed by $2^n - 1$. A value of 4 computes to $2^4 - 1 = 15$.
ECWmax	The exponential (n) value of the maximum contention window size, as expressed by $2^n - 1$. A value of 4 computes to $2^4 - 1 = 15$.
AIFSN	Arbitrary inter-frame space number.
TXOP	Transmission opportunity, in units of 32 microseconds.
ACM	If this column displays a 1, the profile has enabled mandatory admission control. If this column displays a 0, the profile has disabled this feature.

show wlan he-ssid-profile

```
show wlan he-ssid-profile <profile-name>
```

Description

This command shows the configurations of a high-efficiency SSID profile. The optional output modifiers begin, exclude, and include help you display those lines that begin, include, and exclude respectively, the line expression given in the CLI command. The redirect-output modifier helps you redirect the command output.

Parameter	Description
<profile-name>	Name of the high-efficiency ssid profile.

Example

```
(host)[mynode] #show wlan he-ssid-profile default
High-efficiency SSID profile "default"
-----
Parameter Value
-----
High efficiency enable (SSID) Enabled
Dynamic fragmentation level Level-0
HE duration based RTS 1023
Individual TWT Enabled
HE TXBF Enabled
HE Supported MCS map 11,11,11,11,11,11,11,11
HE MU-OFDMA Enabled
HE MU-MIMO Enabled
HE UL MU-MIMO Enabled
HE Guard Interval 800ns 1600ns 3200ns
-----
default 2
Total:1
```

show wlan hotspot advertisement-profile

show wlan hotspot advertisement-profile [<profile-name>]

Description

The output of this command displays settings for a WLAN ANQP advertisement profile. ANQP profiles and H2QP profiles define the 802.11u IEs to be broadcast by an 802.11u capable AP. Use this command to view the ANQP and H2QP profiles to be associated with the advertisement profile.

Use this command without the <profile> parameter to display the entire ANQP advertisement profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of a wlan hotspot advertisement profile.

Examples

The following example shows that the controller has two configured advertisement profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] #show wlan hotspot advertisement-profile
Advertisement Profile List
-----
Name           References  Profile Status
----           -
default        1
Westgate_Mall  2
Total:2.
```

This example displays the configuration settings for the profile **Wireless_rf_profile**.

```
(host)[mynode] (config) #show wlan hotspot advertisement-profile Wireless_
rf_profile
Advertisement Profile "default"
-----
Parameter                               Value
-----
ANQP Venue Name Profile                  venue_mall
ANQP Network Authentication Profile      auth1
ANQP Roaming Consortium Profile          default
```

```

ANQP NAI Realm Profile           Realm2
ANQP 3GPP Cellular Network Profile default
ANQP IP Address Availability Profile ipv4_Profile
H2QP WAN Metrics Profile         default
H2QP Operator Friendly Name Profile default
H2QP Connection Capability Profile default
H2QP Operating Class Indication Profile default
ANQP Domain Name Profile         corp_domain

```

The output of this command includes the following parameters:

Parameter	Description
ANQP Venue Name Profile	Name of the ANQP Venue Name profile associated with this WLAN advertisement profile.
ANQP Network Authentication Profile	Name of the ANQP Network Authentication profile associated with this WLAN advertisement profile.
ANQP Roaming Consortium Profile	Name of the ANQP Roaming Consortium profile associated with this WLAN advertisement profile.
ANQP NAI Realm Profile	Name of the ANQP NAI Realm profile associated with this WLAN advertisement profile.
ANQP 3GPP Profile	Name of the ANQP 3GPP Cellular Network profile associated with this WLAN advertisement profile.
ANQP IP Address Availability Profile	Name of the ANQP IP Address Availability profile associated with this WLAN advertisement profile.
H2QP WAN Metrics Profile	Name of the H2QPWAN Metrics profile associated with this WLAN advertisement profile.
H2QP Operator Friendly Name Profile	Name of the H2QP Operator Friendly Name profile associated with this WLAN advertisement profile.
H2QP Connection Capability Profile	Name of the H2QP Connection Capability profile associated with this WLAN advertisement profile.
H2QP Operating Class Indication Profile	Name of the H2QP Operating Class Indication profile associated with this WLAN advertisement profile.

Parameter	Description
ANQP Domain Name Profile	Name of the ANQP domain name profile associated with this WLAN advertisement profile.

show wlan hotspot anqp-3gpp-nwk-profile

```
show wlan hotspot anqp-3gpp-nwk-profile [<profile-name>]
```

Description

This profile shows the configuration settings for a 3GPP Cellular Network profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u-capable AP. Use this command without the <profile> parameter to display the entire list of 3GPP profiles, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

The 3GPP Cellular Network Profile defines an ANQP IE to be sent in a GAS query response from an AP in a hotspot with a roaming relationship with a cellular operator. The 3GPP mobile country code and the 12-bit Mobile Network Code data in the IE can help the client select a 3GPP network.

Values configured in this profile will not be sent to clients unless you:

Associate the 3GPP Cellular Network profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-3gpp-nwk-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within the Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile-name>	Name of a 3GPP Cellular Network profile.

Examples

The following example shows that the controller has two configured 3GPP profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] (config)#show wlan hotspot anqp-3gpp-nwk-profile
ANQP 3GPP Cellular Network Profile List
-----
Name           References  Profile Status
----           -
default        1
Updated_PLMN   2
Total:2.
```

This example displays the configuration settings for the profile **Updated_PLMN**.

```
(host)[mynode] (config)#show wlan hotspot anqp-3gpp-nwk-profile Updated_PLMN
ANQP 3GPP Cellular Network Profile "Updated_PLMN"
```

```
-----
Parameter                               Value
-----
ANQP 3GPP network profile enable       Enabled
3GPP PLMN1                             310026
3GPP PLMN2                             208000
3GPP PLMN3                             208001
3GPP PLMN4                             N/A
3GPP PLMN5                             N/A
3GPP PLMN6                             N/A
```

The output of this command includes the following parameters:

Parameter	Description
ANQP 3GPP network profile enable	Shows if this profile has been enabled ANQP 3GPP Cellular Network profiles are disabled by default.
3gpp PLMN1	The Public Land Mobile Networks (PLMN) value of the highest-priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp PLMN2	The Public Land Mobile Networks (PLMN) value of the second-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp PLMN3	The Public Land Mobile Networks (PLMN) value of the third-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp PLMN4	The Public Land Mobile Networks (PLMN) value of the fourth-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp PLMN5	The Public Land Mobile Networks (PLMN) value of the fifth-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp PLMN6	The Public Land Mobile Networks (PLMN) value of the sixth-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).

show wlan hotspot anqp-domain-name-profile

```
show wlan hotspot anqp-domain-name-profile [<profile-name>]
```

Description

The output of this command displays settings for a WLAN ANQP Domain Name profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Use this command without the `<profile>` parameter to display the entire ANQP Domain Name profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

Associate the 3GPP Cellular Network profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-3gpp-nwk-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within the Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<code><profile-name></code>	Name of a Domain Name profile.

Examples

The following example shows that the controller has two configured 3GPP profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] #show wlan hotspot anqp-domain-name
ANQP Domain Name Profile List
-----
Name           References  Profile Status
----           -
corp_domain    2
default        1
Total:2.
```

This example displays the configuration settings for the profile **corp_domain**.

```
(host) [mynode] #show wlan hotspot anqp-domain-name-profile corp_domain
```

```

ANQP Domain Name Profile "corp_domain"
-----
Parameter      Value
-----
Domain Name    example.com

```

The output of this command includes the following parameters:

Parameter	Description
Domain Name	Domain name of the hotspot operator.
Profile List	List of available profiles.

show wlan hotspot anqp-ip-addr-avail-profile

```
show wlan hotspot anqp-ip-addr-avail-profile [<profile-name>]
```

Description

The output of this command displays settings for a WLAN ANQP IP Address Availability profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Use this command without the <profile> parameter to display the entire ANQP IP Address Availability profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

Associate the ANQP IP Address Availability profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-ip-addr-avail-profile <profile-name>)

Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)

Enable the hotspot feature within the Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

Parameter	Description
<profile-name>	Name of an IP Address Availability profile.

Examples

The following example shows that the controller has two configured 3GPP profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] # show wlan hotspot anqp-ip-addr-avail-profile
ANQP IP Address Availability Profile List
-----
Name           References  Profile Status
----           -
default        0
ipv4_Profile   2
ipv6_profile   1
Total:3.
```

The following example displays the configuration settings for the profile **ipv4_Profile**.

```
(host)[mynode] #show rf anqp-ip-addr-avail-profile ipv4_Profile
ANQP IP Address Availability Profile "ipv4_Profile"
-----
Parameter                               Value
-----
IPv4 Address Availability Type          public
IPv6 Address Availability Type          not-available
```

The output of this command includes the following parameters:

Parameter	Description
IPv4 Address Availability Type	<p>Indicates the availability of an IPv4 network. This parameter can display any of the following values:</p> <ul style="list-style-type: none"> ▪ availability-unknown: Network availability cannot be determined. ▪ not-available : Network is not available. ▪ port-restricted : Network has some ports restricted (for example, the network blocks port 110 to restrict POP mail). ▪ port-restricted-double-nated : Network has some ports restricted and multiple routers performing network address translation. ▪ port-restricted-single-nated : Network has some ports restricted and a single router performing network address translation. ▪ private-double-nated : Network is a private network with multiple routers doing network address translation. ▪ private-single-nated : Network is a private network a single router doing network address translation. ▪ public : Network is a public network
IPv6 Address Availability Type	<p>Indicates the availability of an IPv6 network. This parameter can display any of the following values:</p> <ul style="list-style-type: none"> ▪ available : An IPv6 network is available. ▪ availability-unknown: Network availability cannot be determined. ▪ not-available : Network is not available.

show wlan hotspot anqp-nai-realm-profile

```
show wlan hotspot anqp-nai-realm-profile [<profile-name>]
```

Description

The output of this command displays settings for a WLAN ANQP Network Access Identifier (NAI) Realm profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Use this command without the <profile> parameter to display the entire ANQP NAI Realm profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

Associate the ANQP NAI Realm profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-nai-realm-profile <profile-name>)

Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)

Enable the hotspot feature within the Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

Parameter	Description
<profile-name>	Name of an NAI Realm profile.

Examples

The following example shows that the controller has two configured 3GPP profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] # show wlan hotspot anqp-nai-realm-profile

ANQP NAI Realm Profile List
-----
Name       References  Profile Status
-----
default    0
Realm1     2Realm2    2

Total:3.
```

The following example shows the configuration settings for the profile **Realm2**.

```
(host)[mynode] #show wlan hotspot anqp-nai-realm-profile Realm2
ANQP NAI Realm Profile "Realm2"
-----
Parameter                               Value
-----
NAI Realm name                           example.com
NAI Realm EAP Method                      eap-ttls
NAI Realm Authentication Parameter Type   expanded-eap
```

The output of this command includes the following parameters:

Parameter	Description
NAI Realm name	Name of the NAI realm. The realm name is often the domain name of the service provider.
NAI Realm EAP Method	The NAI Realm Authentication types sent as an ANQP IE in an GAS response.
NAI Realm Authentication Parameter Type	The EAP authentication method supported by the hotspot realm.

show wlan hotspot anqp-nwk-auth-profile

show wlan hotspot anqp-nwk-auth-profile [<profile-name>]

Description

The output of this command displays settings for a WLAN ANQP network authentication profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Use this command without the <profile> parameter to display the entire ANQP NAI Realm profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an ANQP Network Authentication profile.

Examples

The following example shows that the controller has two configured 3GPP profiles. The **References** column lists the number of other profiles with references to the advertisement profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host)[mynode] # show wlan hotspot anqp-nwk-auth-profile

ANQP Network Authentication Profile List
-----
Name           References  Profile Status
----           -
auth1          0
default        0

Total:2.
```

The following example displays the configuration settings for the profile **default**:

```
(host)[mynode] #show wlan hotspot anqp-nwk-auth-profile default

ANQP Network Authentication Profile "default"
-----
Parameter           Value
-----
Type of Network Authentication  acceptance
```

Redirect URL

N/A

The output of this command includes the following parameters:

Parameter	Description
Type of Network Authentication	Network Authentication Type being used by the hotspot network. This parameter can be any of the following values: <ul style="list-style-type: none">■ acceptance: Network requires the user to accept terms and conditions.■ dns-redirection: Additional information on the network is provided through DNS redirection.■ http-https-redirection : Additional information on the network is provided through HTTP/HTTPS redirection.■ online-enroll : Network supports online enrollment.
Redirect URL	If information on the network is provided through DNS redirection, this parameter displays the redirection URL.

show wlan hotspot anqp-roam-cons-profile

```
show wlan hotspot anqp-roam-cons-profile [<profile>]
```

Description

The output of this command displays settings for a WLAN ANQP Roaming Consortium profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Use this command without the <profile> parameter to display the entire ANQP Roaming Consortium profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Roaming Consortium profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> anqp-roam-cons-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within the Hotspot profile. (wlan hotspot h2-profile <profile-name>hotspot-enable)

Parameter	Description
<profile>	Name of an ANQP Roaming Consortium profile.

Examples

The following example shows two ANQP Roaming Consortium profiles configured on the managed device:

```
(host) # show wlan hotspot anqp-roam-cons-profile
ANQP Roaming Consortium Profile List
-----
Name           References  Profile Status
----           -
default        1
Roam_OI2       1
Total:2.
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the ANQP Roaming Consortium profile.
References	Displays the number of other profiles with references to the ANQP Roaming Consortium profile.
Profile Status	Displays whether the ANQP Roaming Consortium profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example displays the configuration settings for the profile **Roam_OI2**:

```
(host) #show wlan hotspot anqp-roam-cons-profile Roam_OI2
ANQP Roaming Consortium Profile "Roam_OI2"
-----
Parameter                Value
-----
Roaming consortium OI Len 3
Roaming consortium OI Len b32af0
```

The output of this command includes the following parameters:

Parameter	Description
Roaming consortium OI Len	Length of the OI. The roaming consortium OI length parameter is based upon the number of octets of the Roaming consortium OI. This parameter can have the following values: <ul style="list-style-type: none"> ▪ 0: 0 Octets in the OI (Null) ▪ 3: OI length is 24-bit (3 Octets) ▪ 5: OI length is 36-bit (5 Octets)
Roaming Consortium OI	The roaming consortium OI sent in a GAS query response.

Related Command

Command	Description
wlan hotspot anqp-roam-cons-profile	This command configures the Roaming Consortium OI information to be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

show wlan hotspot anqp-venue-name-profile

```
show wlan hotspot anqp-venue-name-profile [<profile>]
```

Description

The output of this command displays settings for a WLAN ANQP Venue Name profile. ANQP profiles define the 802.11u IEs to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP profile to be associated with the advertisement profile.

Use this command without the <profile> parameter to display the entire ANQP Venue Name profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Values configured in this profile will not be sent to clients unless you:

1. Associate the ANQP Venue Name profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-venue-name-profile <profile-name>`)
2. Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)
3. Enable the hotspot feature within the Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile>	Name of an ANQP Venue Name profile.

Examples

The following example shows two ANQP Venue Name profiles configured on the managed device:

```
(host) # show wlan hotspot anqp-venue-name-profile
ANQP Venue Name Profile List
-----
Name           References  Profile Status
----           -
default        0
venue_mall     0
Total:2.
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the ANQP Venue Name profile.
References	Displays the number of other profiles with references to the ANQP Venue Name profile.
Profile Status	Displays whether the ANQP Venue Name profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

This following example shows the configuration settings for the profile **venue_mall**:

```
(host) #show wlan hotspot anqp-venue-name-profile venue_mall
ANQP Venue Name Profile "venue_mall"
-----
Parameter      Value
-----
Venue Group    mercantile
Type of Venue  mercantile-shopping-mall
Venue Name     Westfield_Mall
```

The output of this command includes the following parameters:

Parameter	Description
Venue Group	The venue group to be advertised in the ANQP IEs from APs associated with this profile. This parameter can have any of the following values: <ul style="list-style-type: none"> ▪ assembly ▪ business ▪ educational ▪ factory-or-industrial ▪ institutional ▪ mercantile ▪ outdoor ▪ reserved ▪ residential ▪ storage ▪ unspecified ▪ Utility-Misc ▪ Vehicular

Parameter	Description
Type of Venue	The venue type to be advertised in the IEs from APs associated with this hotspot profile. The complete list of supported venue types is described in Venue Types on page 4155 .
Venue Name	The venue name to be advertised in the ANQP IEs from APs associated with this profile.

show wlan hotspot h2qp-conn-capability-profile

show wlan hotspot h2qp-conn-capability-profile [<profile>]

Description

The output of this command displays settings for a WLAN H2QP connection capability profile. The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about the IP protocols and associated port numbers that are available and open for communication.

Values configured in this profile will not be sent to clients unless you:

1. Associate the H2QP profile with an ANQP advertisement profile. (wlan hotspot advertisement profile <profile-name> h2qp-conn-cap-profile <profile-name>)
2. Associate the ANQP advertisement profile with a Hotspot profile. (wlan hotspot h2-profile advertisement-profile <profile-name>)
3. Enable the hotspot feature within the Hotspot profile. (wlan hotspot h2-profile <profile-name> hotspot-enable)

Parameter	Description
<profile>	Name of H2QP connection capability profile

Examples

Issue this command without the optional <profile> parameter to display a list of all configured connection capability profiles. Include the <profile> parameter to display details for a specific profile.

The following example shows four H2QP connection capability profiles configured on the managed device:

```
(host) (mynode) show wlan hotspot h2qp-conn-capability-profile
H2QP Connection Capability Profile List
-----
Name           References  Profile Status
----           -
branch-hotspot-1  6
branch-hotspot-2  5
default         1
downtown-hotspot  1
Total:4
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the H2QP connection capability profile.
References	Displays the number of other profiles with references to the H2QP connection capability profile.
Profile Status	Displays whether the H2QP connection capability profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows the current configuration settings for the default H2QP connection capability profile:

```
(host) (config) #show wlan hotspot h2qp-conn-capability-profile default
H2QP Connection Capability Profile "default"
-----
Parameter                                     Value
-----
H2QP Connection Capability ICMP port          Disabled
H2QP Connection Capability FTP port(TCP Protocol) Disabled
H2QP Connection Capability SSH port(TCP Protocol) Disabled
H2QP Connection Capability HTTP port(TCP Protocol) Disabled
H2QP Connection Capability TLS VPN port(TCP Protocol) Disabled
H2QP Connection Capability PPTP VPN port(TCP Protocol) Disabled
H2QP Connection Capability VOIP port(TCP Protocol) Disabled
H2QP Connection Capability VOIP port(UDP Protocol) Disabled
H2QP Connection Capability IKEv2 port for IPsec VPN Disabled
H2QP Connection Capability May be used by IKEv2 port for IPsec VPN Disabled
H2QP Connection Capability ESP port(Used by IPsec VPN) Disabled
```

The output of this command includes the following parameters:

Parameter	Description
H2QP Connection Capability ICMP port	Shows if the ICMP port is enabled and available. (port 0)
H2QP Connection Capability FTP port	Shows if the FTP port is enabled and available. (port 20)
H2QP Connection Capability SSH port	Shows if the SSH port is enabled and available. (port 22)
H2QP Connection Capability HTTP port	Shows if the HTTP port is enabled and available. (port 80)
H2QP Connection Capability TLS VPN port	Shows if the TCP TLS port used VPNs is enabled and available. (port 80)

Parameter	Description
H2QP Connection Capability PPTP VPN port	Shows if the PPTP port used by IPsec VPNs is enabled and available. (port 1723)
H2QP Connection Capability VoIP port (UDP)	Shows if the UDP VoIP port is enabled and available. (port 5060)
H2QP Connection Capability VoIP port (TCP)	Shows if the TCP VoIP port is enabled and available. (port 5060)
H2QP Connection Capability IKEv2 port for IPsec VPN	Shows if the IKEv2 port 4500 is enabled and available
H2QP Connection Capability May be used by IKEv2 port for IPsec VPN	Shows if the IKEv2 port 500 is enabled and available
H2QP Connection Capability ESP port (Used by IPsec VPN)	Shows if the ESP port used by IPsec VPNs is enabled and available. (port 0)

show wlan hotspot h2qp-op-cl-profile

```
show wlan hotspot h2qp-op-cl-profile [<profile>]
```

Description

The output of this command displays settings for a WLAN H2QP operating class profile. The values configured in this H2QP Operating Class profile list the channels on which the hotspot is capable of operating. It may be useful where, for instance, a mobile device discovers a hotspot in the 2.4 GHz band but finds it is dual-band and prefers the 5 GHz band.

Parameter	Description
<profile>	Name of H2QP operating class profile.

Examples

Use this command without the optional <profile> parameter to display a list of all configured connection capability profiles. Include the <profile> parameter to display details for a specific profile.

The following example shows two H2QP operating class profiles configured on the managed device. The **References** column lists the number of other profiles with references to the connection capability profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) (H2QP Connection Capability Profile "default") #show wlan hotspot
h2qp-op-cl-profile
H2QP Operating Class Indication Profile List
-----
Name      References  Profile Status
-----
default   0
newopcl   1
Total:2
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the H2QP operating class profile.
References	Displays the number of other profiles with references to the H2QP operating class profile.

Parameter	Description
Profile Status	Displays whether the H2QP operating class profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows the current configuration setting for the default H2QP operating class profile:

```
(host) (H2QP Connection Capability Profile "default") #show wlan hotspot
h2qp-op-cl-profile default
H2QP Operating Class Indication Profile "default"
-----
Parameter                               Value
-----
H2QP Operating Class (Valid Values 1-255) 1
```

The output of this command includes the following parameters:

Parameter	Description
H2QP Operating Class (Valid Values 1-255)	Displays the current operating class for the devices BSS. The supported range for this field is 1-255, and the default value is 1.

Related Command

Command	Description
wlan hotspot h2qp-op-cl-profile	Use this command to configure WLAN H2QP operating class profile.

show wlan hotspot h2qp-operator-friendly-name-profile

show wlan hotspot h2qp-operator-friendly-name-profile [<profile>]

Description

The output of this command displays settings for a H2QP operator-friendly name profile. The operator-friendly name defined in this profile is a free-form text field that can identify the operator and also something about the location. Use this command without the <profile> parameter to display the entire operator-friendly name profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile>	Name of H2QP operator-friendly name profile.

Examples

The following example shows two H2QP operator-friendly name profiles configured on the managed device:

```
(host)(config)# show wlan hotspot h2qp-operator-friendly-name-profile
H2QP Operator Friendly Name Profile List
-----
Name           References  Profile Status
----           -
default        0
operator1      8
Total:2
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the H2QP operator-friendly name profile.
References	Displays the number of other profiles with references to the H2QP operator-friendly name profile.
Profile Status	Displays whether the H2QP operator-friendly name profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows the configuration settings for the profile **operator1**:

```
(host) (H2QP Operator Friendly Name Profile "operator1") #show wlan hotspot
h2qp-operator-friendly-name-profile operator1
H2QP Operator Friendly Name Profile "operator1"
-----
Parameter                               Value
-----
Operator Friendly Name Language Code    eng
Operator Friendly Name                   CoffeeHouseGuest
```

The output of this command includes the following parameters:

Parameter	Description
Operator Friendly Name Language Code	An ISO 639 language code that identifies the language used in the Operator Friendly Name field.
Operator Friendly Name	An operator-friendly name sent by devices using this profile. The name can be up to 64 alphanumeric characters, and can include special characters and spaces. If the name includes quotation marks ("), you must include a backslash character (\) before each quotation mark. (e.g. \"example\")

Related Command

show wlan hotspot h2qp-osu-prov-list-profile

```
show wlan hotspot h2qp-osu-prov-list-profile <profile-name>
```

Description

This command displays settings for a H2QP OSU providers list profile. The name defined in this profile is a free-form text field that can identify the OSU providers list. Use this command without the <profile-name> parameter to display the entire OSU providers profile list. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of the H2QP OSU providers list profile.

Example

The following example shows one H2QP OSU providers list profile configured on the managed device:

```
(host) [mynode] ##show wlan hotspot h2qp-osu-prov-list-profile

H2QP OSU Providers List Profile List
-----
Name      References  Profile Status
-----
test-osu  2
Total:1
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the H2QP OSU providers list profile.
References	Displays the number of other profiles with references to the H2QP OSU providers list profile.
Profile Status	Displays whether the H2QP OSU providers list profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

show wlan hotspot h2qp-wan-metrics-profile

```
show wlan hotspot h2qp-wan-metrics-profile [<profile-name>]
```

Description

The output of this command displays settings for a H2QP WAN metrics profile. The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about access network characteristics such as link status and the capacity and speed of the WAN link to the Internet. Use this command without the `<profile-name>` parameter to display the entire WAN metrics profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<code><profile-name></code>	Name of H2QP WAN metrics profile.

Examples

The following example shows two H2QP WAN metrics profiles configured on the managed device:

```
(host) [mynode] (H2QP Connection Capability Profile "default") #show wlan
hotspot h2qp-wan-metrics-profile

H2QP WAN Metrics Profile List
-----
Name      References  Profile Status
-----
default   0
fastwan   6
Total:2
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the H2QP WAN metrics profile.
References	Displays the number of other profiles with references to the H2QP WAN metrics profile.
Profile Status	Displays whether the H2QP WAN metrics profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows the current configuration settings for the profile **fastwan**:

```
(host) [mynode] #show wlan hotspot h2qp-wan-metrics-profile fastwan

H2QP WAN Metrics Profile "fastwan"
-----
Parameter                               Value
-----
H2QP WAN metrics link status            link_up
H2QP WAN metrics symmetric WAN link     Disabled
H2QP WAN metrics link at capacity       Disabled
WAN Metrics uplink speed                 1000
WAN Metrics downlink speed              1000
WAN Metrics uplink load                  100
WAN Metrics downlink load                100
WAN Metrics load measurement duration    100
```

The output of this command includes the following parameters:

Parameter	Description
H2QP WAN metrics link status	Indicates the status of the WAN Link by displaying one of the following values. The default link status is reserved , which indicates that the link status is unknown or unspecified. <ul style="list-style-type: none"> link_down link_test link_up reserved
H2QP WAN metrics symmetric WAN link	This parameter indicates if the WAN Link has same speed in both the uplink and downlink directions.
H2QP WAN metrics link at capacity	This parameter indicates if the WAN Link has reached its maximum capacity. If this parameter is enabled, no additional mobile devices will be permitted to associate to the hotspot AP.
WAN Metrics uplink speed	This parameter indicates the current WAN backhaul uplink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the uplink speed is unknown or unspecified.
WAN Metrics downlink speed	This parameter indicates the current WAN backhaul downlink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.
WAN Metrics uplink load	The percentage of the WAN uplink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.

Parameter	Description
WAN Metrics downlink load	The percentage of the WAN downlink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified.
WAN Metrics load measurement duration	Duration over which the downlink load is measured, in tenths of a second.

Related Command

show wlan hotspot hs2-profile

```
show wlan hotspot hs2-profile [<profile-name>]
```

Description

The output of this command displays settings for a Hotspot 2.0 profile. Organization Identifiers (OIs) are assigned to service providers when they register with the IEEE registration authority. The Roaming Consortium IEs contain information identifying the network and service provider, whose security credentials can then be used to authenticate with the AP transmitting this element.

The OI for the service provider is defined in the ANQP Roaming Consortium profile using the [wlan hotspot anqp-roam-cons-profile](#) command. This Hotspot profile allows you to define and send up to three additional OIs to a client. The configurable values for each additional OI include the Organization Identifier itself, the OI length, and the venue group and venue type associated with those OIs.

Use this command without the `<profile-name>` parameter to display the entire ANQP advertisement profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<code><profile-name></code>	Name of a Hotspot 2.0 profile.

Examples

The following example shows two Hotspot profiles configured on the managed device:

```
(host) [mynode] # show wlan hotspot hs2-profile

Hotspot 2.0 Profile List
-----
Name           References  Profile Status
----           -
default        1
Hotspot_1      2
Total:2
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the Hotspot 2.0 profile.

Parameter	Description
References	Displays the number of other profiles with references to the Hotspot 2.0 profile.
Profile Status	Displays whether the Hotspot 2.0 profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows configuration settings defined for the profile **Hotspot1**:

```
(host) [mynode] #show wlan hotspot hs2-profile Hotspot1

Hotspot 2.0 Profile "default"

```

The output of this command includes the following parameters:

Parameter	Description
Advertise Hotspot 2.0 Capability	Shows if this profile has been enabled.
Additional Steps required for Access Enabled	<p>If this parameter is enabled, the AP will send the following IEs (IEs) in response to the client's the ANQP query.</p> <ul style="list-style-type: none"> ▪ Venue Name ▪ Domain Name List ▪ Network Authentication Type ▪ Roaming Consortium List ▪ NAI Realm List <p>NOTE: If asra is enabled, the advertisement profile for this hotspot must reference an enabled network authentication type profile. For more information on enabling an network authentication type profile, see wlan hotspot anqp-nwk-auth-profile on page 4150.</p>
Network Internet Access	If enabled, the AP sends an Information Element (IE) indicating that the network allows internet access. By default, a hotspot profile does not advertise network internet access.
Length of Query Response	The maximum length of the GAS query response, in octets. The supported range is 1-255 octets.
Access network Type	<p>The 802.11u network type. The default setting is public-chargeable.</p> <ul style="list-style-type: none"> ▪ emergency-services: emergency services only network ▪ personal-device: personal device network ▪ private: private network ▪ private-guest: private network with guest access ▪ public-chargeable: public chargeable network ▪ public-free: free public network ▪ test: test network ▪ wildcard: wildcard network
Roaming Consortium Len Entry 1	<p>Length of the OI. This value is based upon the number of octets in the Roaming Consortium OI Entry 1 field.</p> <ul style="list-style-type: none"> ▪ 0: Zero Octets in the OI (Null) ▪ 3: OI length is 24-bit (3 Octets) ▪ 5: OI length is 36-bit (5 Octets)

Parameter	Description
Roaming Consortium OI Entry 1	Roaming consortium OI assigned to one of the service provider's top three roaming partners. This additional OI will only be sent to a client if the Additional Roaming Consortium OI's (displayed in Advertisement Profile) parameter is set to 1 or higher.
Roaming Consortium Len Entry 2	Length of the OI. This value is based upon the number of octets in the Roaming Consortium OI Entry 2 field. <ul style="list-style-type: none"> ▪ 0: Zero Octets in the OI (Null) ▪ 3: OI length is 24-bit (3 Octets) ▪ 5: OI length is 36-bit (5 Octets)
Roaming Consortium OI Entry 2	Roaming consortium OI assigned to one of the service provider's top three roaming partners. This additional OI will only be sent to a client if the Additional Roaming Consortium OI's (displayed in Advertisement Profile) parameter is set to 2 or higher.
Roaming Consortium Len Entry 3	Length of the OI. This value is based upon the number of octets in the Roaming Consortium OI Entry 3 field. <ul style="list-style-type: none"> ▪ 0: Zero Octets in the OI (Null) ▪ 3: OI length is 24-bit (3 Octets) ▪ 5: OI length is 36-bit (5 Octets)
Roaming Consortium OI Entry 3	Roaming consortium OI assigned to one of the service provider's top three roaming partners. This additional OI will only be sent to a client if the Additional Roaming Consortium OI's (displayed in Advertisement Profile) parameter is set to 3 or higher.
Additional Roaming Consortium OI's (displayed in Advertisement Profile)	Number of additional roaming consortium Organization Identifiers (OIs) advertised by the AP.
Venue Group Type	The venue groups to be advertised in the IEs from APs associated with this hotspot profile. The default setting is unspecified .
Venue Type	Venue type to be advertised in the IEs from APs associated with this hotspot profile.
Type of Hotspot 2.0 Indication Element	Advertisement protocol types to be used by the AP. <ul style="list-style-type: none"> ▪ anqp: Access Network Query Protocol ▪ emergency: Emergency Alert System

Parameter	Description
	<ul style="list-style-type: none"> ▪ mih-cmd-event: Media Independent Handover (MIH) Command and Event Services Capability Discovery ▪ mih-info: Media Independent Handover (MIH) Information Service. This option allows handovers between differing kinds of wireless access protocols and technologies, allowing access points on different IP subnets to communicate with each other at the link level while maintaining session continuity.
Advertisement Profile	Advertisement profile associated with this hotspot profile.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config mode on Mobility Conductor.

show wlan ht-ssid-profile

```
show wlan ht-ssid-profile [<profile-name>]
```

Description

This command displays the list of all high-throughput SSID profiles, or detailed configuration information for a specific high-throughput SSID profile. Use this command without the `<profile-name>` parameter to display the entire high-throughput SSID profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<code><profile-name></code>	Name of a high-throughput SSID profile.

Examples

The following example shows three high-throughput SSID profiles configured on the managed device:

```
(host) [mynode] #show wlan ht-ssid-profile

High-throughput SSID profile List
-----
Name                               References  Profile Status
----                               -
default                             2
dot1X_CP-htssid_prof                1
ade-sloan-htssid_prof               1

Total:3
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the high-throughput SSID profile.
References	Displays the number of other profiles with references to the high-throughput SSID profile.
Profile Status	Displays whether the high-throughput SSID profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows configuration settings defined for the profile **default**:

```
(host) #show wlan ht-ssid-profile default

High-throughput SSID profile "default"
-----
Parameter                                     Value
-----
High throughput enable (SSID)                 Enabled
40 MHz channel usage                         Enabled
Very High throughput enable (SSID)           Enabled
80 MHz channel usage (VHT)                   Enabled
BA AMSDU Enable                              Enabled
Temporal Diversity Enable                    Disabled
Legacy stations                              Allowed
Low-density Parity Check                     Enabled
Maximum number of spatial streams usable for STBC reception 1
Maximum number of spatial streams usable for STBC transmission 1
MPDU Aggregation                             Enabled
Max received A-MPDU size                     65535 bytes
Max transmitted A-MPDU size                  65535 bytes
Min MPDU start spacing                       0 usec
Short guard interval in 20 MHz mode           Enabled
Short guard interval in 40 MHz mode           Enabled
Short guard interval in 80 MHz mode           Enabled
Supported MCS set                            0-31
VHT - Supported MCS map                      9,9,9,9
VHT - Explicit Transmit Beamforming           Enabled
VHT - Transmit Beamforming Sounding Interval 25 msec
VHT - Multi User Transmit Beamforming         Enabled
Maximum VHT MPDU size                        11454 bytes
Maximum number of MSDUs in an A-MSDU on best-effort AC 2 MSDUs
Maximum number of MSDUs in an A-MSDU on background AC 2 MSDUs
Maximum number of MSDUs in an A-MSDU on video AC 2 MSDUs
Maximum number of MSDUs in an A-MSDU on voice AC 0 MSDUs
```

The output of this command includes the following parameters:

Parameter	Description
High throughput enable (SSID)	Displays if the high-throughput (802.11n) feature is enabled or disabled on the SSID. Default: Enabled.
40 MHz channel usage	Shows if the profile enables or disables the use of 40 MHz channels. Default: Enabled.
Very High throughput enable (SSID)	Displays if the very high-throughput (802.11ac) feature is enabled or disabled on the SSID. Default: Enabled.
80 MHz channel usage (VHT)	Displays the status of the 80 MHz channel for very high-throughput is enabled or disabled.

Parameter	Description
	Default: Enabled.
BA AMSDU Enable	Displays if the AP has enabled or disabled the ability to receive Aggregated-MAC Service Data Unit (A-MSDU) in Block ACK (BA) negotiation. Default: Enabled.
Temporal Diversity Enable	Displays if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries. Default: Disabled.
Legacy stations	Allows or disallows associations from legacy (non-HT) stations. By default, this parameter is enabled (legacy stations are allowed).
Low-density Parity Check	If enabled, the AP will advertise Low-density Parity Check (LDPC) support. LDPC improves data transmission over radio channels with high levels of background noise. Default: Enabled.
Maximum number of spatial streams usable for STBC reception	Displays the maximum number of spatial streams usable for Space-Time Block Code (STBC) reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the AP-105, 130 Series, and 170 Series only. The configured value will be adjusted based on AP capabilities.) NOTE: If transmit beamforming is enabled, STBC will be disabled for beamformed frames.
Maximum number of spatial streams usable for STBC transmission	Displays the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on AP-105, 130 Series, and 170 Series only. The configured value will be adjusted based on AP capabilities.) NOTE: If transmit beamforming is enabled, STBC will be disabled for beamformed frames.
MPDU Aggregation	Displays if the profile enables or disables MAC Protocol Data Unit (MPDU) aggregation. Default: Enabled.

Parameter	Description
Max received A-MPDU size	Displays the configured maximum size of a received aggregate MPDU, in bytes.
Max transmitted A-MPDU size	Displays the configured maximum size of a transmitted aggregate MPDU, in bytes.
Min MPDU start spacing	Displays the configured minimum time between the start of adjacent MPDUs within an aggregate MPDU, in microseconds.
Short guard interval in 20 MHz mode	Displays if the profile enables or disables use of short (400 ns) guard interval in 20 MHz mode. Default: Enabled.
Short guard interval in 40 MHz mode	Displays if the profile enables or disables use of short (400 ns) guard interval in 40 MHz mode. Default: Enabled.
Short guard interval in 80 MHz mode	Displays if the profile enables or disables use of short (400 ns) guard interval in 80 MHz mode. Default: Enabled.
Supported MCS set	<p>Displays a list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20 MHz vs. 40 MHz vs. 80 MHz) and the number of spatial streams used by the mesh node.</p> <p>Default: 0-31</p> <ul style="list-style-type: none"> ▪ MCS value of 16-23 are supported on 130 Series, RAP-155, and 11ac APs only. ▪ MCS value of 24-31 are supported on 320 Series APs only.
VHT - Supported MCS map	<p>Displays a list of supported MCS map for very high throughput SSID. Comma separated list of maximum supported MCS for spatial streams 1 through 4. Valid values for maximum MCS are 7, 8, 9, and '-' (if spatial stream is not supported). Maximum MCS of a spatial stream cannot be higher than the previous streams. If an MCS is not valid for a particular combination of bandwidth and number of spatial streams, it will not be used for Tx and Rx.</p> <p>Default: 9,9,9,9.</p>

Parameter	Description
VHT - Explicit Transmit Beamforming	<p>Displays if VHT Explicit Transmit Beamforming status is enabled or disabled for the 802.11ac-capable APs. When this feature is enabled, the AP requests information about the MIMO channel and uses that information to transmit data over multiple transmit streams using a calculated steering matrix. The result is higher throughput due to improved signal at the beamformee (the receiving client). If this parameter is disabled, all other transmit beamforming settings will not take effect. Default: Enabled.</p>
VHT - Transmit Beamforming Sounding Interval	<p>Displays the time interval in milliseconds between updates of VHT Transmit Beamforming channel estimation. (802.11ac-capable APs only)</p> <p>NOTE: This is applicable for 802.11ac-capable APs only.</p> <p>Default: 25 milliseconds.</p>
VHT - Multi User Transmit Beamforming	<p>Displays if the VHT Multi-User Transmit Beamforming is enabled or disabled. If this parameter is disabled, all other Multi-User Transmit Beamforming configuration parameters have no effect.</p> <p>NOTE: This parameter is applicable for 320 Series APs only.</p> <p>Default: Enabled.</p>
Maximum VHT MPDU size	<p>Displays the maximum size of a VHT MPDU. Default: 11454 bytes.</p>
Maximum number of MSDUs in an A-MSDU on best-effort AC	<p>Displays the maximum number of MSDUs in a TX A-MSDU on best-effort Access Category (AC). Default: 2.</p> <p>NOTE: In tunnel and decrypt-tunnel forwarding mode, TX A-MSDU is disabled if the value is set to 0. If the value is set to non-zero, TX A-MSDU is enabled and set to this value.</p>
Maximum number of MSDUs in an A-MSDU on background AC	<p>Displays the maximum number of MSDUs in a TX A-MSDU on background AC. Default: 2.</p> <p>NOTE: TX A-MSDU is disabled if the value is set to 0. In decrypt-tunnel forwarding mode, TX A-MSDU on background AC is disabled and</p>

Parameter	Description
	assigning any value has no effect.
Maximum number of MSDUs in an A-MSDU on video AC	Displays the maximum number of MSDUs in a TX A-MSDU on video AC. Default: 2. NOTE: TX A-MSDU is disabled if the value is set to 0. In decrypt-tunnel forwarding mode, TX A-MSDU on video AC is disabled and assigning any value has no effect.
Maximum number of MSDUs in an A-MSDU on voice AC	Displays the maximum number of MSDUs in a TX A-MSDU on voice AC. Default: 0. NOTE: TX A-MSDU is disabled if the value is set to 0. In decrypt-tunnel forwarding mode, TX A-MSDU on voice AC is disabled and assigning any value has no effect.

show wlan mu-edca-parameters-profile

```
show wlan mu-edca-parameters-profile <profile-name>
```

Description

This command displays the MU EDCA Parameters profiles. The optional output modifiers begin , exclude, and include help you display those lines that begin, include, and exclude respectively, the line expression given in the CLI command. The redirect-output modifier helps you redirect the command output.

Parameter	Description
<profile-name>	Name of the MU EDCA parameter profile.

Example

The following example shows an MU EDCA Parameters profile configured on the managed device:

```
(host)[mynode] #show wlan mu-edca-parameters-profile
MU EDCA Parameters profile List
-----
Name      References  Profile Status
-----
default  1
Total:1
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the MU EDCA Parameters profile.
References	Displays the number of other profiles with references to the MU EDCA Parameters profile.
Profile Status	Displays whether the MU EDCA Parameters profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

show wlan rrm-ie-profile

```
show wlan rrm-ie-profile [<profile-name>]
```

Description

This command displays the list of all radio resource management information element (RRM IE) profiles, or the detailed configuration information for a specific RRM IE profile. Use this command without the <profile-name> parameter to display the entire RRM IE profile list. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of an RRM IE profile.

Examples

The following example shows an RRM IE profile configured on the managed device:

```
(host) [mynode] #show wlan rrm-ie-profile

RRM IE Profile List
-----
Name                               References  Profile Status
----                               -
test-rrm-profile                   1
Total:1
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the RRM IE profile.
References	Displays the number of other profiles with references to the RRM IE profile.
Profile Status	Displays whether the RRM IE profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows the configuration information for the **default** RRM IE profile:

```
(host) [mynode] #show wlan rrm-ie-profile default

RRM IE Profile "default"
-----
Parameter                               Value      Set
-----

show wlan sae-profile

```
show wlan sae-profile
```

Description

This command displays the WPA3 Simultaneous Authentication of Equals (SAE) profiles. The optional output modifiers `begin`, `exclude`, and `include` help you display those lines that begin, include, and exclude respectively, the line expression given in the CLI command. The `redirect-output` modifier helps you redirect the command output.

Example

The following example shows an SAE profile configured on the managed device:

```
(host)[mynode] #show wlan sae-profile
WPA3 SAE Configuration
-----
Parameter                               Value
-----
Auth Frame Retransmit Interval <20-1000>ms 100
SAE Anti-Clogging token threshold <0-1000> 5
SAE Giveup threshold <1-20>                5
```

show wlan ssid-profile

```
show wlan ssid-profile [<profile-name>]
```

Description

This command displays the list of all SSID profiles, or detailed configuration information for a specific SSID profile. Use this command without the `<profile-name>` parameter to display the entire SSID profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<code><profile-name></code>	Name of an SSID profile.

Examples

The following example shows six SSID profiles configured on the managed device:

```
(host) [mynode] #show wlan ssid-profile

SSID Profile List
-----
Name                               References  Profile Status
----                               -
coltrane-ssid-profile              1
corp1 -ssid-profile                3
Remote                             1
Secure-Profile2                   0
test-ssid-profile                  1
wizardtest-ssid-profile            1

Total:6
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the SSID profile.
References	Displays the number of other profiles with references to the SSID profile.
Profile Status	Displays whether the SSID profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows configuration settings defined for the SSID Profile **Remote**:

```
(host) [mynode] #show wlan ssid-profile remote

SSID Profile "Remote"
-----
Parameter                               Value
-----

```

The output of this command includes the following parameters:

Parameter	Description
SSID	Shows if the profile has enabled or disabled this SSID.
ESSID	Name that uniquely identifies a wireless network. If the ESSID includes spaces, you must enclose it in quotation marks.
Encryption	The layer-2 authentication and encryption type used on this ESSID.
Enable Management Frame Protection	Enables management frame protection.
Require Management Frame Protection	If enabled, requires management frame protection.
DTIM Interval	The interval, in milliseconds, between the sending of Delivery Traffic Indication Messages (DTIMs) in the beacon.
802.11a Basic Rates	List of supported 802.11a rates, in Mbps, that are advertised in beacon frames and probe responses.
802.11a Transmit Rates	Set of 802.11a rates at which the AP is allowed to send data.
802.11g Basic Rates	List of supported 802.11b/g rates, in Mbps, that are advertised in beacon frames and probe responses.
802.11g Transmit Rates	Set of 802.11b/g rates at which the AP is allowed to send data.
Station Ageout Time	Time, in seconds, that a client is allowed to remain idle before being aged out.
Station Refresh Direction	The refresh direction of WLAN SSID profile.
Max Transmit Attempts	Maximum transmission failures allowed before the client gives up.

Parameter	Description
RTS Threshold	Wireless clients transmitting frames larger than this defined threshold must issue Request to Send (RTS) and wait for the AP to respond with Clear to Send (CTS).
Short Preamble	Shows if the profile enables or disables short preamble for 802.11b/g radios
Max Associations	Maximum number of wireless clients for the AP
Wireless Multimedia (WMM)	Shows if the profile enables or disables WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function (EDCF)
Wireless Multimedia U-APSD (WMM-UAPSD) Powersave	Shows if the profile enables or disables Wireless Multimedia (WMM) UAPSD powersave.
WMM TSPEC Min Inactivity Interval	Specifies the minimum inactivity time-out threshold of WMM traffic.
DSCP mapping for WMM voice AC	DSCP value used to map WMM voice traffic.
DSCP mapping for WMM video AC	DSCP value used to map WMM video traffic.
DSCP mapping for WMM best-effort AC	DSCP value used to map WMM best-effort traffic.
DSCP mapping for WMM background AC	DSCP value used to map WMM background traffic.
902iL Compatibility Mode	(For clients using NTT DoCoMo 902iL phones only) When enabled, the managed device does not drop packets from the client if a small or old initialization vector value is received.
Hide SSID	Shows if the profile enables or disables hiding of the SSID name in beacon frames.
Deny_Broadcast Probes	When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID.
Local Probe Response	Shows if the profile enables or disables local probe response on the AP. If this option is enabled, the AP is responsible for sending 802.11 probe responses to wireless clients' probe requests. If this option is disabled, then the managed device sends the 802.11 probe responses.

Parameter	Description
Auth Request Threshold (dB)	Displays the SNR threshold below which incoming authentication requests are ignored.
Disable Probe Retry	Shows if the profile enables or disables battery MAC level retries for probe response frames.
Battery Boost	If enabled, this feature converts multicast traffic to unicast before delivery to the client, thus allowing you to set a longer DTIM interval.
WEP Key 1	Displays the Static WEP key associated with this key index.
WEP Key 2	Displays the Static WEP key associated with this key index.
WEP Key 3	Displays the Static WEP key associated with this key index.
WEP Key 4	Displays the Static WEP key associated with this key index.
WEP Transmit Key Index	Shows the key index that specifies which static WEP key is to be used.
WPA Hexkey	WPA pre-shared key (PSK).
WPA Passphrase	WPA passphrase used to generate a pre-shared key (PSK).
Maximum Transmit Failures	Maximum transmission failures allowed before the client gives up.
EDCA Parameters Station profile	Name of the enhanced distributed channel access (EDCA) Station profile that applies to this SSID.
EDCA Parameters AP profile	Name of the enhanced distributed channel access (EDCA) AP profile that applies to this SSID.
BC/MC Rate Optimization	Shows if the profile enables or disables scanning of all active stations currently associated to an AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate.
Rate Optimization for delivering EAPOL frames	If this option is enabled, APs using this profile will use a more conservative rate for more reliable delivery of EAPOL frames.
Strict Spectralink Voice Protocol (SVP)	Shows if the profile enables or disables strict Spectralink Voice Protocol (SVP).

Parameter	Description
High-throughput SSID Profile	Name of the high-throughput SSID profile associated with this SSID profile.
802.11g Beacon Rate	The beacon rate for 802.11g (use for Distributed Antenna System (DAS) only). Using this parameter in normal operation may cause connectivity problems.
802.11a Beacon Rate	The beacon rate for 802.11a (use for Distributed Antenna System (DAS) only). Using this parameter in normal operation may cause connectivity problems.
Video Multicast Rate Optimization	The rate for video multicast frames.
Advertise QBSS Load IE	<p>Enables the AP to advertise the QBSS load element. The element includes the following parameters that provide information on the traffic situation:</p> <ul style="list-style-type: none"> ▪ Station count: The total number of stations associated to the QBSS. ▪ Channel utilization: The percentage of time (normalized to 255) the channel is sensed to be busy. The access point uses either the physical or the virtual carrier sense mechanism to sense a busy channel. ▪ Available admission capacity: The remaining amount of medium time (measured as number of 32us/s) available for a station via explicit admission control. <p>The QAP uses these parameters to decide whether to accept an admission control request. A wireless station uses these parameters to choose the appropriate access points.</p>
Advertise Location Info	APs that are part of this VAP will broadcast their GPS coordinates in the beacons and probe response frames as part of a vendor-specific Information Element.
Advertise AP Name	If this parameter enabled, APs will broadcast the AP name configured by the ap-name command. This option is disabled by default.
802.11r Profile	The associated dot11r-profile with the SSID profile.
Enforce user vlan for open stations	Shows the strict enforcement of data traffic only in user's assigned vlan (Open stations only).
Enable OKC	The status of the Opportunistic Key Caching.

Parameter	Description
	Opportunistic Key Caching (OKC) is a similar technique, not defined by 802.11i, available for authentication between multiple APs in a network where those APs are under common administrative control. An Aruba deployment with multiple APs under the control of a single controller is one such example. Using OKC, a station roaming to any AP in the network will not have to complete a full authentication exchange, but will instead just perform the 4-way handshake to establish transient encryption keys.

show wlan traffic-management-profile

show wlan traffic-management-profile [<profile-name>]

Description

This command displays the list of all traffic management profiles, or detailed configuration information for a specific traffic management profile. Issue this command without the <profile-name> parameter to display the entire traffic management profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of a traffic management profile.

Examples

The following example shows two traffic management profiles configured on the managed device:

```
(host) [mynode] #show wlan traffic-management-profile

Traffic management profile List
-----
Name           References  Profile Status
-----
mgmt1          3
mgmt2          2
Total:2
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the traffic management profile.
References	Displays the number of other profiles with references to the traffic management profile.
Profile Status	Displays whether the traffic management profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows configuration settings defined for the profile **mgmt1**:

```
(host) [mynode] #show wlan traffic-management-profile mgmt1

Traffic management profile "default"
-----
Parameter                Value
-----
Proportional BW Allocation N/A
Report interval           5 min
Station Shaping Policy    default-access
```

The output of this command includes the following parameters:

Parameter	Description
Proportional BW Allocation	Minimum bandwidth, as a percentage of available bandwidth, allocated to an SSID when there is congestion on the wireless network. An SSID can use all available bandwidth if no other SSIDs are active.
Report interval	Number of minutes between bandwidth usage reports.
Station Shaping Policy	Shows which of three possible Station Shaping policies is configured on the profile. <ul style="list-style-type: none">▪ default-access: Traffic shaping is disabled, and client performance is dependent on MAC contention resolution. This is the default traffic shaping setting.▪ fair-access: Each client gets the same airtime, regardless of client capability and capacity. This option is useful in environments like a training facility or exam hall, where a mix of 802.11a/g, 802.11g and 802.11n clients need equal to network resources, regardless of their capabilities. The bw-alloc parameter of a traffic management profile allows you to set a minimum bandwidth to be allocated to a virtual AP profile when there is congestion on the wireless network. You must set traffic shaping to fair-access to use this bandwidth allocation value for an individual virtual AP.▪ preferred-access: High-throughput (802.11n) clients do not get penalized because of slower 802.11a/g or 802.11b transmissions that take more air time due to lower rates. Similarly, faster 802.11a/g clients get more access than 802.11b clients.

show wlan tsm-req-profile

```
show wlan tsm-req-profile [<profile-name>]
```

Description

This command displays configuration and other information about the parameters for the Transmit Stream and Category Measurement (TSM) Request frames. Issue this command without the <profile-name> parameter to display the entire TSM Request profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

For this profile to take effect, the 802.11K feature needs to be enabled.

Parameter	Description
<profile-name>	Name of a TSM Report Request profile. The name must be between 1-63 characters.

Example

The following example shows the parameters description of a TSM Report Request profile:

```
(host) [mynode] #show wlan tsm-req-profile default

TSM Report Request Profile "default"
-----
Parameter                               Value
-----
Request Mode for TSM Report Request      normal
Number of repetitions                     65535
Duration Mandatory                       Enabled
Randomization Interval                   0
Measurement Duration                      25
Traffic ID                               96
Bin 0 Range                              200
```

The output of this command includes the following parameters:

Parameter	Description
Request mode for TSM Report Request	Shows the request mode for the Transmit Stream and Category Measurement Request frame.
Number of repetitions	Shows the "Number of Repetitions" field in the Transmit Stream and Category Measurement Request frame.

Parameter	Description
Duration Mandatory	Shows the "Duration Mandatory" part of the Measurement Request Mode field of the Transmit Stream and Category Measurement Request frame.
Randomization Interval	Shows the Randomization Interval field in the Transmit Stream and Category Measurement Request frame.
Measurement Duration	Shows the Measurement Duration field in the Transmit Stream and Category Measurement Request frame.
Traffic ID	Shows the Traffic Identifier field in the Transmit Stream and Category Measurement Request frame.
Bin 0 Range	Shows the ' Bin 0 Range ' field in the Transmit Stream and Category Measurement Request frame.

show wlan virtual-ap

show wlan virtual-ap [<profile-name>]

Description

Displays the list of all virtual AP profiles, or detailed configuration information for a specific virtual AP profile. Issue this command without the <profile-name> parameter to display the entire virtual AP profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<profile-name>	Name of a virtual AP profile.

Examples

The following example shows six virtual AP profiles configured on the managed device.

```
(host) [mynode] #show wlan virtual-ap

Virtual AP profile List
-----
Name                               References  Profile Status
----                               -
coltrane-vap-profile                1
default
MegTest
Remote                               1
test-vap-profile                    1
wizardtest-vap-profile              1
Total: 6
```

The output of this command includes the following parameters.

Parameter	Description
Name	Displays the name of the virtual AP profile.
References	Displays the number of other profiles with references to the virtual AP profile.
Profile Status	Displays whether the virtual AP profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows the configuration settings defined for the profile **wizardtest-vap-profile**.

```
(host) [mynode] #show wlan virtual-ap test-vap-profile

Virtual AP profile "wizardtest-vap-profile"
-----
Parameter                               Value
-----

VLAN Mobility                              Disabled
FDB Update on Assoc                       Disabled
WMM Traffic Management Profile             N/A
Anyspot Profile                           N/A
```

The output of this command includes the following parameters.

Parameter	Description
AAA Profile	Name of the AAA profile associated with this virtual AP.
802.11K Profile	Name of an 802.11k profile associated with this virtual AP.

Parameter	Description
SSID Profile	Name of an SSID profile associated with this virtual AP.
Virtual AP enable	Shows if the profile enables or disables the virtual AP.
VLAN	The VLAN(s) into which users are placed in order to obtain an IP address.
Forward mode	<p>Forwarding mode defined on the profile:</p> <ul style="list-style-type: none"> ▪ tunnel mode ▪ bridge mode ▪ split-tunnel mode ▪ decrypt-tunnel mode <p>The forwarding mode controls whether data is tunneled to the managed device using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the managed device, and Internet access remains local).</p> <p>When an AP is configured to use the decrypt-tunnel forwarding mode, that AP decrypts and decapsulates all 802.11 frames from a client and sends the 802.3 frames through the GRE tunnel to the managed device, which then applies firewall policies to the user traffic. When the managed device sends traffic to a client, the managed device sends 802.3 traffic through the GRE tunnel to the AP, which then converts it to encrypted 802.11 and forwards to the client.</p>
Allowed band	<p>The band(s) on which to use the virtual AP:</p> <ul style="list-style-type: none"> ▪ a—802.11a band only (5 GHz) ▪ g—802.11b/g band only (2.4 GHz) ▪ all—both 802.11a and 802.11b/g bands (5 GHz and 2.4 GHz)

Parameter	Description
Allowed 5G radio	<p>The 5 GHz radio(s) on which to configure the virtual AP:</p> <ul style="list-style-type: none"> ■ all—dual 5 GHz band only ■ first-5g-radio-only—first 5 GHz band only ■ second-5g-radio-only—second 5 GHz band only <p>NOTE: This parameter is ignored if the AP has only one 5 GHz radio.</p>
Allow 6GHz band	<p>Disable or enable 6 GHz band to use the virtual AP.</p> <p>NOTE: This parameter is applicable to Wi-Fi 6E APs only.</p>
Disable 6GHz vap for mesh	<p>Disable or enable virtual AP on 6 GHz band. If enabled, virtual AP is disabled on 6 GHz band only when AP is provisioned as mesh.</p> <p>NOTE: This parameter is applicable to Wi-Fi 6E APs only.</p>
Band Steering	<p>If enabled, ARM's band steering feature encourages dual-band capable clients to stay on the 5GHz band on dual-band APs. This frees up resources on the 2.4 GHz band for single band clients like VoIP phones.</p>
Fine Timing Measurement (802.11mc) Responder Mode	<p>Shows if 802.11 mc Fine Timing Measurement (FTM) on radio (responder mode) is enabled for 500 Series, 500H Series, 510 Series, 530 Series, 550 Series, 560 Series, 570 Series, 630 Series, and 650 Series access points.</p>
Steering Mode	<p>Band steering supports three different band steering modes:</p> <ul style="list-style-type: none"> ■ Force-5GHz: When the AP is configured in force-5GHz band steering mode, the AP will try to force 5 Ghz-capable APs to use that radio band.

Parameter	Description
	<ul style="list-style-type: none"> ▪ Prefer-5GHz (Default): If you configure the AP to use prefer-5GHz band steering mode, the AP will try to steer the client to 5G band (if the client is 5G capable) but will let the client connect on the 2.4G band if the client persists in 2.4G association attempts. ▪ Balance-bands: In this band steering mode, the AP tries to balance the clients across the two radios in order to best utilize the available 2.4G bandwidth. This feature takes into account the fact that the 5Ghz band has more channels than the 2.4 GHz band, and that the 5 GHz channels operate in 40 MHz while the 2.5 GHz band operates in 20 MHz. <p>NOTE: Steering modes do not take effect until the band steering feature has been enabled. The band steering feature in ArubaOS versions 3.3.2-5.0 does not support multiple band-steering modes. The band-steering feature in these versions of ArubaOS functions the same way as the default prefer-5GHz steering mode available in ArubaOS 6.0 and later.</p>
Dynamic Multicast Optimization (DMO)	If enabled DMO techniques will be used to reliably transmit video data.
Dynamic Multicast Optimization (DMO) Threshold	Maximum number of high-throughput stations in a multicast group beyond which dynamic multicast optimization stops.

Parameter	Description
Drop Broadcast and Multicast	If enabled, the virtual AP will filter out broadcast and multicast traffic in the air.
Convert Broadcast ARP requests to unicast	If enabled, all broadcast ARP requests are converted to unicast and sent directly to the client.
Authentication Failure Blacklist/Denylist Time	Time, in seconds, a client is blocked if it fails repeated authentication. An authentication failure blacklist/denylisttime of 0 blocks failed users indefinitely.
Blacklist/Denylist Time	Number of seconds that a client is quarantined from the network after being blacklisted/denylisted.
Deny Inter User Traffic	<p>This option, when enabled, denies traffic between the clients using this virtual AP profile.</p> <p>The <code>firewall</code> command includes an option to deny all inter-user traffic, regardless of the Virtual AP profile used by those clients.</p> <p>If the global setting to deny inter-user traffic is enabled, all inter-user traffic between clients will be denied, regardless of the settings configured in the virtual AP profiles. If the setting to deny inter-user traffic is disabled globally but enabled on an individual virtual ap, only the traffic between un-trusted users and the clients on that particular virtual AP will be blocked.</p>
Deny time range	Time range for which the AP will deny access.
DoS Prevention	If enabled, APs ignore deauthentication frames from clients. This prevents a successful deauth attack from being carried out against the AP. This does not affect third-party APs.

Parameter	Description
HA Discovery on-association	<p>If enabled, home agent discovery is triggered on client association instead of home agent discovery based on traffic from client. Mobility on association can speed up roaming and improve connectivity for clients that do not send many uplink packets to trigger mobility (VoIP clients). Best practices is to leave this parameter disabled as it increases IP mobility control traffic between controllers in the same mobility domain. Enable this parameter only when voice issues are observed in VoIP clients.</p> <p>NOTE: <code>ha-disc-onassoc</code> parameter works only when IP mobility is enabled and configured on the controller.</p>
Mobile IP	Shows if the profile has enabled or disabled IP mobility.
Preserve Client VLAN	This parameter allows clients to retain their previous VLAN assignment if the client disassociates from an AP and then immediately re-associates either with same AP or another AP on same controller.
Remote-AP Operation	<p>Shows when the virtual AP operates on a remote AP:</p> <ul style="list-style-type: none"> ▪ always—Permanently enables the virtual AP (Bridge Mode only). This option can be used for non-802.1X bridge VAPs. ▪ backup—Enables the virtual AP if the remote AP cannot connect to the controller (Bridge Mode only). This option can be used for non-802.1X bridge VAPs. ▪ persistent—Permanently enables the virtual AP after

Parameter	Description
	<p>the remote AP initially connects to the controller (Bridge Mode only). This option can be used for any (Open/PSK/802.1X) bridge VAPs.</p> <ul style="list-style-type: none"> ▪ standard—Enables the virtual AP when the remote AP connects to the controller. This option can be used for any (bridge/split-tunnel/tunnel/d-tunnel) VAPs.
Station Blacklisting/Denylisting	Shows if the profile has enabled or disabled detection of denial of service (DoS) attacks, such as ping or SYN floods, that are not spoofed death attacks.
Strict Compliance	If enabled, the AP denies client association requests if the AP and client station have no common rates defined. Some legacy client stations which are not fully 802.11-compliant may not include their configured rates in their association requests. Such non-compliant stations may have difficulty associating with APs unless strict compliance is disabled.
Multi Association	If enabled, this feature allows a station to be associated to multiple APs. If this feature is disabled, when a station moves to new AP it will be de authorized by the AP to which it was previously connected, deleting station context and flushing key caching information
Fast Roaming	Shows if the AP has enabled or disabled fast roaming.
VLAN Mobility	Shows if the AP has enabled or disabled VLAN (Layer-2) mobility.

Parameter	Description
WMM Traffic Management Profile	WMM Traffic Management Profile associated with this Virtual AP Profile
Anyspot profile	Anyspot Profile associated with this Virtual AP Profile

show wlan wmm-traffic-management-profile

show wlan wmm-traffic-management-profile [<profile-name>]

Description

Displays the list of all WMM traffic management profiles, or detailed configuration information for a specific WMM traffic management profile. Issue this command without the <profile-name> parameter to display the entire WMM traffic management profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
profile-name>	Name of the WMM traffic management profile.

Examples

The following example shows two WMM traffic management profiles configured on the managed device:

```
(host) [mynode] #show wlan wmm-traffic-management-profile

WMM Traffic management profile List
-----
Name          References  Profile Status
-----
default       3
test          2

Total:2
```

The output of this command includes the following parameters:

Parameter	Description
Name	Displays the name of the WMM traffic management profile.
References	Displays the number of other profiles with references to the WMM traffic management profile.
Profile Status	Displays whether the WMM traffic management profile is predefined. NOTE: User-defined profiles do not have an entry in the Profile Status column.

The following example shows configuration settings defined for the profile **test**:

```
(host) [mynode] #show wlan traffic-management-profile test

WMM Traffic management profile "test"
-----
Parameter          Value
-----
Enable Shaping Policy true
Voice Share         40 %
Video Share         43 %
Best-effort Share   10 %
Background Share    7 %
```

The output of this command includes the following parameters:

Parameter	Description
Enable Shaping Policy	Displays if WMM based traffic shaping is enabled on the managed device.
Voice Share	Displays the bandwidth allocation in percentage (%) for voice access traffic category.
Viceo Share	Displays the bandwidth allocation in percentage (%) for video access traffic category.
Best-effort Share	Displays the bandwidth allocation in percentage (%) for best effort access traffic category.
Background Share	Displays the bandwidth allocation in percentage (%) for background access traffic category.

show wms ap

```
show wms ap {<bssid>|list <essid> |stats [mon-mac <mon-mac> bssid <bssid>]|tree}
```

Description

This command displays information for APs currently monitored by the Wireless Management System (WMS). The WMS feature periodically sends statistics that it has collected for APs and Probes to the WMS process. When WMS receives an event message from an AM, it will save the event information along with the BSSID of the AP that generated the event in the WMS database. When WMS receives statistics from the AM, it updates its state, and the database.

Parameter	Description
<bssid>	Enter the AP's BSSID number in hexadecimal format (XX:XX:XX:XX:XX:XX).
list	Shows the list of all APs monitored by WMS.
<essid>	Shows the details of that particular ESSID.
stats	Shows the AP Statistics table for all APs.
mon-mac <mon-mac>	Shows the AP Tree table for an AP with the specified MAC address.
bssid <bssid>	Shows the AP Tree table for an AP with the specified BSSID.
tree	Show the APs seen by each monitoring probe in the WMS.

Examples

The following example displays a list of AP MAC addresses and the BSSIDs seen by each AP along with reclassification of the monitored AP triggered by the user:

```
(host) [mynode] #show wms ap 00:0d:67:20:db:4b
AP Info
-----
BSSID      SSID  Channel  Type          RAP_Type          Status
Ageout    HT-Type  HT-Sec-Chan
-----  -----  -----  -----  -----  -----
70:3a:0e:6e:2a:71      64      generic-ap  suspected-rogue (40%)  up

```

The output of this command includes the following parameters:

Column	Description
AP Info	
BSSID	Basic Service Set Identifier (BSSID) for the AP. This is usually the AP's MAC address.
SSID	The Service Set Identifier (SSID) that identifies a wireless network.
Channel	Channel used by the AP radio.
Type	A WMS AP type can be one of the following: <ul style="list-style-type: none"> ▪ soft-ap: An Aruba Access Point (AP). ▪ air-monitor: An Aruba Air Monitor (AM).
RAP_Type	Indicates one of the following Rogue AP types: <ul style="list-style-type: none"> ▪ Valid (not a rogue AP) ▪ Interfering ▪ Rogue ▪ Suspected Rogue ▪ Disabled Rogue ▪ Unclassified ▪ Known Interfering
Status	If up, the AP is active. If down (or no information is shown) the AP is inactive.
Ageout	An ageout time is the time, in minutes, that the client must remain unseen by any probes before it is eliminated from the database. If this column displays a -1, the client has not yet aged out. Any other number indicates the number of minutes since the client has passed its ageout interval.
HT-type	The type of high-throughput traffic sent by the AP:

Column	Description
	<ul style="list-style-type: none"> ▪ HT-20mhz: The AP radio uses a single 20 MHz channel ▪ HT-40mhz: The AP radio uses a 40 MHz channel pair comprised of two adjacent 20 MHz channels.
HT-Sec-Chan	Secondary channel used for 40 MHz high-throughput transmissions.
Match Info	
<p>NOTE: Depending on the match type or the classification, the Match Info table may be displayed containing all or some of the following fields:</p>	
Match-Type	Indicates the type of matching detected by the AP.
Match-Source	Indicates the source of the manual reclassification. This field is displayed only when the AP has the match type Manual .
Match-Time	Indicates the time of matching for any match type.
Rule-Name	Indicates the AP classification rule name defined by the user.
Helper-BSSID	
Match-Method	Indicates the condition used to match the discovered AP with the match type.
Match-MAC	Indicates the MAC address of a wired device that helped identify the AP as rogue or suspected-rogue. If the AP has not been identified as a rogue, this column displays the MAC address 00:00:00:00:00:00 .
Match-AP	Indicates the valid AP name that matches successfully with the AP classification.
Probe Info	
MAC	MAC address of a probe that can see the specified AP.
IP	IP address of a probe that can see the specified AP.
Name	Name of the probe.
Type	Displays the probe type: A WMS probe can be one of the following: <ul style="list-style-type: none"> ▪ soft-ap: An Aruba Access Point (AP). ▪ air-monitor: An Aruba Air Monitor (AM).
Status	If up, the AP is active. If down (or no information is shown) the AP is inactive.
AP Type	AP model type.

The following example displays received and transmitted data statistics for each BSSID seen by a monitoring AP. (For versions prior to ArubaOS 8.9.0.0)

The output of this command includes the following parameters:

Column	Description
BSSID	MAC address of an AP.
ESSID	The Extended Service Set Identifier (SSID) that identifies a wireless network.
Class	The classification of the monitored AP. Following are the classification types: <ul style="list-style-type: none"> valid interfering suspected-rogue neighbor rogue manually-contained
PHY Type (For versions prior to ArubaOS 8.9.0.0)	Displays one of the following radio bands: <ul style="list-style-type: none"> 802.11a 802.11b 802.11g 802.11ag
Band (ArubaOS 8.9.0.0 or later versions)	Displays one of the following radio bands: <ul style="list-style-type: none"> 2.4GHz 5GHz 6GHz
AP-name	Name of the AP.
Encryp	Encryption type used on each listed AP.

Column	Description
IBSS	Displays if ad hoc BSS is enabled or disabled on each listed AP.
Last Mon Eth MAC	Displays the last monitored MAC address seen on the wired network for the AP.
Match-Type	Indicates the type of matching detected by the AP.
Match-Source	Indicates the source of the manual reclassification. This field displays information only when the classification is manual.
Match-Time	Indicates the time of matching for manual or any other match type.

The following example displays received and transmitted data statistics for each BSSID seen by a monitored AP.

```

show wms client

```
show wms client {list|<mac>|probe <mac>|stats [mon-mac <mon-mac> mac <mac>]|tree|valid-exempt}
```

Description

This command displays the list of client information for the clients that can be seen by monitoring APs.

Parameter	Description
list	Show statistics for all monitored clients.
<mac>	Show statistics for a client with the specified MAC address, including the BSSID of the AP to which that client is currently associated, and the MAC addresses of other monitoring APs that can see that client.
probe <mac>	Specify a client's MAC address to show the BSSIDs of all probes that can see that client.
stats	Show the STA stats table, which displays data for all clients seen by each monitoring AP.
mon-mac <mon-mac> mac <mac>	Enter a monitoring AP's MAC address (<mon-mac>) and the MAC address of a client (<mac>) to show data for traffic received from and sent to a specific client as seen by a specific AP.
tree	Shows a list of the clients seen by each monitoring probe.
valid-exempt	Shows a list of valid-exempt clients.

Example

The following example shows statistics for a client with the specified MAC address, including the BSSID of the AP to which that client is currently associated with. The **AP Info** table in the example below shows that the client is associated to an AP with the BSSID **00:0b:86:cd:86:a0**. The **Probe Info** table shows the MAC addresses of three other APs that can see the client. (For versions prior to ArubaOS 8.9.0.0)

```
(host) [mynode] #show wms client 00:0e:35:29:9b:28
Probe Info
-----
MAC                Type   Status  Ageout  HT-Type
---                -
00:0e:35:29:9b:28  valid  up      -1      HT-40mhz
```

```

AP Info
-----
BSSID          SSID      Channel  Type      RAP_Type  Status  Ageout
HT-Type      HT-Sec-Chan
-----
00:0b:86:cd:86:a0  MySSID  11      soft-ap  valid     up      -1
HT-40mhz    153

```

In the following example, the **AP Info** table also shows the radio band along with the channel used by the radio, the high-throughput traffic sent by the AP, and the secondary channel used for high-throughput transmissions. (ArubaOS 8.9.0.0 or later versions)

```

(host) [mynode] #show wms client 84:d4:7e:e6:17:50

AP Info
-----
BSSID          SSID          Band/Chan/HT-Type/HT-Sec-Chan  Type

Probe Info
-----
MAC          IP      Name      Type      Status  AP Type
-----
84:d4:7e:e6:17:50  1.1.1.6  qc-225  soft-ap  up      225

```

The output of this command includes some or all of the following parameters.

Column	Description
MAC	MAC address of a WMS probe.
Type	Station type (valid , interfering , or disabled rogue client).

Column	Description
Status	If up , the client is active. If down (or no information is shown) the client is inactive.
Ageout	An ageout time is the time, in minutes, that the client must remain unseen by any probes before it is eliminated from the database. If this column displays a -1 , the client has not yet aged out. Any other number indicates the number of minutes since the client has passed its ageout interval.
BSSID	BSSID of the AP to which the client is associated.
SSID	Extended service set identifier (ESSID) of the BSSID.
Channel (For versions prior to ArubaOS 8.9.0.0)	Channel used by the AP radio.
Type	<p>A WMS AP type can be one of the following:</p> <ul style="list-style-type: none"> ▪ soft-ap: Aruba Access Point (AP). ▪ air-monitor: Aruba Air Monitor (AM).

Column	Description
RAP_Type	<p>Indicates one of the following Rogue AP types:</p> <ul style="list-style-type: none"> ▪ Valid (not a rogue AP) ▪ Interfering ▪ Rogue ▪ Disabled Rogue ▪ Suspected Rogue ▪ Unclassified ▪ Known Interfering
Status	<p>If up, the AP is active. If down (or no information is shown) the AP is inactive.</p>
Ageout	<p>An ageout time is the time, in minutes, that the client must remain unseen by any probes before it is eliminated from the database. If this column displays a -1, the client has not yet aged out. Any other number indicates the number of minutes since the client has passed its ageout interval.</p>
HT-Type (For versions prior to ArubaOS 8.9.0.0)	<p>Type of high-throughput traffic sent by the AP.</p>
HT-Sec-Chan (For versions prior to ArubaOS 8.9.0.0)	<p>Secondary channel used for high-throughput transmissions.</p>

Column	Description
Band/Chan/HT-Type/HT-Sec-Chan (ArubaOS 8.9.0.0 or later versions)	Displays information in the order of the radio band/radio channel/high-throughput traffic type/secondary channel used for high-throughput traffic.
IP	IP address of a WMS probe.
AP type	Model type of the probe.

The following example lists the statistics for all monitored clients. (ArubaOS 8.9.0.0 or later versions)

```
(host) [mynode] (config) #show wms client list

Station List
-----
MAC          BSSID          ESSID   Class          Band  Last Mon
Eth MAC
---          -
-----
fc:b3:bc:45:36:de  1c:28:af:68:28:c2  ssid-1  interfering    6GHz
cc:88:c7:cc:16:46
Total:1
```

The output of this command includes the following parameters.

Column	Description
MAC	MAC address of the client.
BSSID	BSSID of the AP to which the client is associated.
ESSID	Extended service set identifier (ESSID) of the BSSID.
Class	The classification of the monitored AP. Following are the classification types: <ul style="list-style-type: none"> ■ valid ■ interfering ■ suspected-rogue ■ neighbor ■ rogue ■ manually-contained

Column	Description
Band	The AP radio band. Following are the possible values: <ul style="list-style-type: none"> ■ 2.4GHz ■ 5GHz ■ 6GHz
Last Mon Eth MAC	The last monitored MAC address seen on the wired network for the AP.

show wms counters

```
show wms counters [debug|events|rap-ack]
```

Description

This command displays WMS events and debug counters. If you omit the optional `debug` and `events` parameters, the `show wms counters` command displays the frequently used (general) counters in a single table. This command displays counters for database entries, messages, and data structures. The counters displayed vary for each managed device; if the managed device does not have an entry for a particular counter type, it does not appear in the output of this command.

Parameter	Description
<code>debug</code>	Displays debug counters only.
<code>events</code>	Displays events counters only.
<code>rap-ack</code>	Displays number of pending PROBE_RAP_ACK for each probe.

Example

The following example shows output for the `show wms counters` command:

```
(host) [mynode] #show wms counters
Counters
-----
Name                               Value
----                               -

Column	Description
Monitor Eth MAC	Ethernet MAC address of a probe.
BSSID	Probe Radio BSSID.
PHY Type (For versions prior to ArubaOS 8.9.0.0)	Radio PHY type: <ul style="list-style-type: none"> ■ 802.11A ■ 802.11AHT-40Mbps ■ 802.11AHT-20Mbps ■ 802.11G ■ 802,11GHT-20Mbps
Band/HT-Type (ArubaOS 8.9.0.0 or later versions)	The radio band and the high-throughput traffic type sent by the AP. Displays one of the following radio bands: <ul style="list-style-type: none"> ■ 2.4GHz ■ 5GHz ■ 6GHz
IP	IP address of the AP.
LMS IP	IP address of the AP's managed device.
Scan	Shows if the Air Monitor is performing scanning.
Status	If the scan column displays a status of Up, the AP or AM is active
Updates	Number of updates the AP or AM sent to the WMS database since the managed device was last reset.

Column	Description
Reqs/Fails	Number of database update requests that have not yet been added into the database, and the number of failed database requests.
Stats	Total number of statistics updates sent to the database.
Type	A WMS AP type can be one of the following: <ul style="list-style-type: none"> ▪ soft-ap: An Aruba Access Point (AP). ▪ air-monitor: An Aruba Air Monitor (AM).

show wms rogue-ap

```
show wms rogue-ap <bssid> [list]
```

Description

This command displays statistics for APs classified as rogues APs. The optional output modifiers `begin`, `exclude`, and `include` help you display those lines that begin, include, and exclude respectively, the line expression given in the CLI command. The `redirect-output` modifier helps you redirect the command output.

Parameter	Description
<bssid>	BSSID of a rogue AP.
list	Shows rogue AP list.

Examples

The following example shows statistics for a suspected rogue AP based on the BSSID.

```
(host) [mynode] #show wms rogue-ap 00:0b:86:d4:ca:12
Suspect Rogue AP Info
-----
Key                Value
---                -
BSSID              00:0b:86:d4:ca:12
SSID               aruba-ap
Band/Chan/HT-Type/HT-Sec-Chan 5GHz/36/VHT-80mhz/-
Type               generic-ap
RAP Type           suspected-rogue
Status             up
Match Type         AP-Rule
Match MAC          00:0b:86:61:8a:d0
Match IPv4         0.0.0.0
Match IPv6         0.0.0.0
Match AM           ssahoo-155
Match Method       Exact-Match
Helper AP BSSID    a8:bd:27:22:8b:70
Match Time         Sun Sep 19 19:11:40 2010
```

The output of this command includes the following information:

Column	Description
BSSID	BSSID of the suspected rogue AP.

Column	Description
SSID	The rogue AP's Extended service set identifier.
Channel (For versions prior to ArubaOS 8.9.0.0)	Channel used by a radio on the rogue AP.
Band/Chan/HT-Type/HT-Sec-Chan (ArubaOS 8.9.0.0 or later versions)	Displays information in the order of the radio band/radio channel/high-throughput traffic type/secondary channel used for high-throughput traffic.
Type	Indicates if the AP is an Aruba AP, a Cisco AP, or an AP from any other manufacturer (generic AP).
RAP Type	Type of rogue AP, <ul style="list-style-type: none"> ▪ Suspect-unsecure: AP has not been confirmed as a rogue AP. ▪ unsecure: AP has been confirmed as a rogue AP.
Status	Shows if the AP is active (up) or inactive (down).
Match Type	Describes how the AP was classified as a rogue. <ul style="list-style-type: none"> ▪ Eth-Wired-MAC: An Aruba AP or AM detected that a single MAC address was in both the Ethernet Wired-Mac table and a non-valid AP wired-Mac table. ▪ AP-Wired-MAC: An interfering AP is marked as rogue when the Aruba AP finds a MAC address in one of its valid AP wired-mac table and in an interfering AP wired-mac table. You can enable or disable the AP-Wired-MAC matching method using the CLI command ids unauthorized-device-profile overlay-classification. ▪ Config-Wired-MAC: This type of classification occurs when an Aruba AP or AM detects a match between a wired MAC table and a pre-defined MAC address that has manually defined via the command ids unauthorized-device-profile . ▪ External-Wired-MAC: This type of classification occurs when an Aruba AP or AM detects a match between a wired MAC table entry and a pre-defined MAC address manually defined in the ids rap-wml-server-profile table.

Column	Description
	<ul style="list-style-type: none"> ▪ Base-BSSID-Override: If an Aruba AP is detected as rogue, then all virtual APs on the particular rogue are marked as rogue using Base-BSSID-Override match type. ▪ Manual: An AP is manually defined as a rogue by via the command <code>wms ap <bssid> mode rogue</code>. ▪ EMS: An AP is manually defined as a rogue by via the Element Management System.
Match MAC	MAC address of a wired device that helped identify the AP as a rogue. If the AP has not been identified as a rogue, this column will display the MAC address 00:00:00:00:00:00.
Match IPv4	IPv4 address of a wired device that helped identify the AP as a rogue.
Match IPv6	IPv6 address of a wired device that helped identify the AP as a rogue.
Match AM	Aruba Air Monitor that reported seeing the rogue AP.
Match Method	This variable indicates the type of match.
Match Time	Time the AP was identified as a rogue AP.

The following example shows statistics for a suspected rogue AP list. (ArubaOS 8.9.0.0 or later versions)

```
(host) [mynode] (config) #show wms rogue-ap list

AP List
-----
BSSID          ESSID    Class      Band  AP-name  Encryp  IBSS  Last

Total:1
```

The output of this command includes the following parameters:

Column	Description
BSSID	MAC address of an AP.
ESSID	The Extended Service Set Identifier (SSID) that identifies a wireless network.
Class	The classification of the monitored AP. Following are the classification types: <ul style="list-style-type: none"> ▪ valid ▪ interfering ▪ suspected-rogue ▪ neighbor ▪ rogue ▪ manually-contained
Band	The AP radio band. Following are the possible values: <ul style="list-style-type: none"> ▪ 2.4GHz ▪ 5GHz ▪ 6GHz
AP-name	Name of the AP.
Encryp	Encryption type used on each listed AP.
IBSS	Displays if ad hoc BSS is enabled or disabled on each listed AP.
Last Mon Eth MAC	Displays the last monitored MAC address seen on the wired network for the AP.
Match-Type	Indicates the type of matching detected by the AP.
Match-Source	Indicates the source of the manual reclassification. This field displays information only when the classification is manual.
Match-Time	Indicates the time of matching for manual or any other match type.

show wms rogue-ap list

```
show wms rogue-ap list
```

Description

This command displays the information on the rogue APs in the network. When an AM classifies an interfering AP as a Rogue AP it sends that classification to the WMS process.

Use this command to list all known Rogue APs that may be potential security threats.

Examples

The `show wms rogue-ap list` command displays a list of rogue APs detected in the network.

```
(host)[mynode] #show wms rogue-ap list
AP List
-----
BSSID          ESSID          Class  PHY Type AP-name Encryp      IBSS  Last

show wms routers

```
show wms routers [<mac>]
```

Description

This command displays learned router MAC information for WMS APs. This command displays the MAC addresses of devices that have been determined to be routers by the listed APs. This output of this command will be blank if there is not any broadcast or multicast activity in an AP's subnet.

Parameter	Description
<mac>	MAC address of a probe that can see the router.

Example

In the example below, a single WMS AP has learned MAC information for four different routers.

```
(host) [mynode] #show wms routers
Router Mac 00:08:00:00:11:12 is Seen by APs
-----
AP-Name
-----

show wms rules

```
show wms rules
  config
  state
  summary
```

Description

This command displays the internal state and matching information of rules created using the [ids ap-classification-rule](#) command. Issue this command to view existing AP classification rules. AP classification rule configuration can only be performed on a Mobility Conductor. If AMP is enabled via the mobility-manager command, then processing of the AP classification rules is disabled on Mobility Conductor. A rule is identified by its ASCII character string name (32 characters maximum).

The AP classification rules have one of the following specifications:

- SSID of the AP
- SNR of the AP
- Discovered-AP-Count or the number of APs that can see the AP

Parameter	Description
config	Displays the following information for each AP classification rule: <ul style="list-style-type: none">▪ name▪ ids▪ match-ssid▪ min-snr▪ max-snr▪ min-prcnt▪ max-prcnt▪ ssids▪ enabled▪ classify▪ conf-incr▪ flags▪ match-cnt
state	Displays the following information for each AP classification rule: <ul style="list-style-type: none">▪ SSID Match Table▪ SSID Exclude Table▪ SNR Table▪ Probe Count Table
summary	Displays a summary of AP classification rules.

Example

The output in the example below shows that although two rules have been defined, neither have been enabled using the `ids ap-rule-matching rule-name <name>` command.

```
(host) [mynode] #show wms rules summary

show wms wired-mac

```
show wms wired-mac {gw-mac [<mac>]|monitored-ap-wm [<mac>]|prop-eth-mac  
[<mac>]|reg-ap-oui [<mac>]|summary|system-gw-mac [<mac>]|system-wired-mac  
[<mac>]|wireless-device [<mac>}}
```

Description

This command displays a summary table of WLAN Management System (WMS) wired MAC information. This command can display a list of APs aware of a specific gateway MAC address, or list the wired MAC addresses known to a single AP.

Column	Description
gw-mac	Shows gateway wired MAC information collected from the APs.
<mac>	Displays information for a single MAC address.
monitored-ap-wm	Shows monitored AP wired MAC information collected from the APs.
<mac>	Displays information for a single MAC address.
prop-eth-mac	Shows wired mac information collected from the APs.
<mac>	Displays information for a single MAC address.
reg-ap-oui	Shows registered AP OUI information collected from the APs, including each registered OUI, and the time that OUI was last seen.
<mac>	Displays information for a single MAC address.
summary	Display a wired MAC summary that includes the number of each of the following MAC types: <ul style="list-style-type: none">Registered AP OUIsPropagated Ethernet MACs.Potential Wireless Device MACsMonitored AP Wired MACsSystem Wired MACsSystem Gateway MACs
system-gw-mac	Shows system gateway MAC information learned at the managed device, including the age of each MAC address.
<mac>	Displays information for a single MAC address.

Column	Description
system-wired-mac	Shows system wired MAC information learned at the managed device.
<mac>	Displays information for a single MAC address.
wireless-device	Show routers or potential wireless devices information, including the MAC address of the device, and the MAC address of the AP or managed device that saw the device.
<mac>	Displays information for a single MAC address.

Example

The following example shows the wired MAC summary:

```
(host) [mynode] #show wms wired-mac summary
Wired MAC Summary
-----
Type                               Count
----                               -
Gateway MACs                       1
Registered AP OUIs                 16
Propagated Ethernet MACs           0
Potential Wireless Device MACs     0
Monitored AP Wired MACs             0
System Wired MACs                   0
System Gateway MACs                 0
```

Related Commands

show ip interface brief

```
show ip interface brief
```

Description

This command displays the IP-related information on all interfaces in summary format.

Example

```
(host) #show ip interface brief
Interface                IP Address / IP Netmask      Admin  Protocol
VRRP-IP
vlan 1                   172.16.0.254 / 255.255.255.0  up     up
vlan 2                   10.4.62.9 / 255.255.255.0     up     up
loopback                 unassigned / unassigned      up     up
mgmt                    unassigned / unassigned      down   down
```

The following table details the columns and content in the show command.

Column	Description
Interface	List the interface and interface identification, where applicable.
IP Address /IP Netmask	List the IP address and netmask for the interface, if configured.
Admin	States the administrative status of the interface. Enabled—up Disabled—down
Protocol	Status of the IP on the interface. Enabled—up Disabled—down
VRRP-IP	VRRP IP address associated to the interface.

snmp-server

```
snmp-server
  community <string>
  enable
  engine-id
  host IPv4/IPv6 Address|version {1 <name> udp-port <port> [trap-group <SNMP trap
group name>]}|2c|{3 <name>}
  [inform] [interval <seconds>] [retrycount <number>] [udp-port <port>]
  [trap-group <SNMP trap group name>]}
  inform queue-length <size>
  source controller-ip
  stats
  trap {source [IPv4|IPv6 Address]|<name>}
  trap-group <SNMP trap group name>
    [snmp-server trap <trap-name>]
  user
    <word>
    [auth-prot {md5|sha} <string>]
    [priv-prot {AES|DES} <string>]
```

Description

This command configures SNMP parameters. It configures SNMP related information for APs in an SNMP profile, which is applied to an AP group or to a specific AP.

Parameter	Description
community	Sets the read-only community string.
enable	Enables sending of SNMP traps to the configured host. disabled
engine-id	Sets the SNMP server engine ID as a hexadecimal number. 24 characters maximum
host	Configures the IPv4/IPv6 Address of the host to which SNMP traps are sent. This host needs to be running a trap receiver to receive and interpret the traps sent by the controller.
version	Configures the SNMP version and security string for notification messages.
inform	Sends SNMP inform messages to the configured host. disabled

Parameter	Description
inform	Specifies the length for the SNMP inform queue. 100-350 250
stats	Allows file-based statistics collection. The Mobility Conductor/Mobility Conductor generates a file that contains statistics data to display information in chart and graph formats. File-based statistics collection is transparent to the user and increases the efficiency of transferring information. enabled
trap {source [IPv4 IPv6 Address] <name>}	Configures source IPv4 or IPv6 address or name of SNMP traps. disabled
trap-group <SNMP trap group name> [snmp-server trap <trap-name>]	Configures an SNMP trap group that stores specific traps within that group.
user	Configures an SNMPv3 user profile.
<word>	USM security model user name
[auth-prot [md5 sha] <string>]	Authentication protocol of the user and the password to use with the protocol. MD5/SHA SHA
[priv-prot {AES DES} <string>]	Privacy protocol of the user and the password to use with the protocol. AES/DES DES

Example

The following example configures an SNMP user:

```
(host) [mynode] (config) #snmp-server user temp auth-prot md5 temp12 priv-prot aes temp34
```

The following example configures an SNMP trap group:

```
(host) [mynode] (config) #snmp-server trap-group System
(host) ^[mynode] (config-submode)#snmp-server trap wlsxFlashSpaceOK
(host) ^[mynode] (config-submode)#snmp-server trap wlsxMemoryUsageOK
(host) ^[mynode] (config-submode)#snmp-server trap wlsxPowerSupplyOK
(host) ^[mynode] (config-submode)#snmp-server trap wlsxFanOK
```

Command History:

Release	Modification
ArubaOS 8.11.0.0	A new SNMP trap, wlsxLicenseThresholdLimitHit was added.
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.8.0.0	The <code>trap-group <SNMP trap group name></code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor/Mobility Conductor .

spanning-tree

```
spanning-tree
  forward-time <value>
  hello-time <value>
  max-age <value>
  mode <rapid> | <rapid-pvst>
  priority <value>
  vlan range {<word>|[remove <word> {forward-time|hello-time|max-age|priority}]}
```

RSTP is backward compatible with STP and is enabled by default. For ease of use, this command uses the spanning tree keyword.

Description

This command configures global settings for the Rapid Spanning Tree Protocol (RSTP) and Per VLAN Spanning Tree (PVST+). Refer to [interface gigabitethernet](#) for details on enabling and configuring spanning tree for an individual interface. This command configures the global RSTP settings and is backward compatible with past versions of ArubaOS using STP.

By default, all interfaces and ports run RSTP as specified in 802.1w and 802.1D. The default RSTP values can be used for most implementations.

Use the `no spanning-tree` command to disable RSTP.

Parameter	Description
<code>forward-time</code>	Specifies the time, in seconds, the port spends in the listening and learning state. During this time, the port waits to forward data packets. Range: 4-30 Default: 15 seconds
<code>hello-time</code>	Specifies the time, in seconds, between each bridge protocol data unit (BPDU) transmitted by the root bridge. Range: 1-10 Default: 2 seconds
<code>max-age</code>	Specifies the time, in seconds, the root bridge waits to receive a hello packet before changing the STP topology. Range: 6-40 Default: 20 seconds
<code>mode</code>	Set the spanning tree mode to either Rapid Spanning Tree (802.1w) or PVST+ (Per VLAN Spanning Tree)
<code><rapid></code>	Set the spanning tree mode to RSTP (Rapid Spanning Tree Protocol).

Parameter	Description
<rapid-pvst>	Set the spanning tree mode to PVST+ (Per VLAN Spanning Tree protocol)
priority	Set the priority of a bridge to make it more or less likely to become the root bridge. The bridge with the lowest value has the highest priority. When configuring the priority, remember the following: The highest priority bridge is the root bridge. The highest priority value is 0 (zero). Range: 0-65535 Default: 32768
vlan range <WORD>	Enter the keywords vlan range followed by the range of VLAN ID's. Separate the VLAN IDs with a hyphen, comma or both to indicate the range. For example: 2-3 or 2,4,6 or 2-6,11
remove <word>	Removes range of VLAN IDs.
remove <word> forward-time	Removes the spanning tree forward interval.
remove <word> hello-time	Removed the spanning tree hello interval.
remove <word> max-age	Removes the spanning tree maximum age interval.
remove <word> priority	Removes the spanning tree priority interval.

Examples

The following command sets the time a port spends in the listening and learning state to 3 seconds:

```
(host) [mynode] #spanning-tree forward-time 3
```

The following command sets the time the root bridge waits to transmit BPDUs to 4 seconds:

```
(host) [mynode] #spanning-tree hello-time 4
```

The following command sets the time the root bridge waits to receive a hello packet to 30 seconds:

```
(host) [mynode] #spanning-tree max-age 30
```

The following command sets the bridge priority to 10, making it more likely to become the root bridge:

```
(host) [mynode] #spanning-tree priority 10
```

The follow command sets a spanning-tree VLAN range

```
(host) [mynode] #spanning-tree vlan range 2-8,11
```

Command History:

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

ssh

ssh

```
disable-ciphers {aes-cbc | aes-ctr}
disable-kex
disable-mac {hmac-sha1 | hmac-sha1-96}
disable_dsa
mgmt-auth {public-key [username/password] | username/password [public-key]}
<username> <ip_addr>
```

Description

This command configures SSH access to a Mobility Conductor. Public key authentication is supported using a X.509 certificate issued to the management client. If you specify public-key authentication, you need to load the client X.509 certificate into Mobility Conductor and configure certificate authentication for the management user with the `mgmt-user ssh-pubkey` command.

The SSH authentication supports **hmac-sha1**, **hmac-sha1-96**, and **hmac-sha2-256** by default.

The `hmac-sha2-256` parameter can not be disabled.

Parameter	Description
<code>disable-ciphers</code>	Disables cipher authentication for SSH. Specify the cipher to be disabled.
<code>aes-cbc</code>	Disables AES-CBC authentication for SSH. This parameter enables the aes-ctr encryption.
<code>aes-ctr</code>	Disables AES-CTR authentication for SSH. This parameter enables the aes-cbc encryption.
<code>disable-kex</code>	Disables key exchange algorithm for SSH authentication.
<code>disable-mac</code>	Disables Message Authentication Code algorithm for SSH authentication.
<code>hmac-sha1</code>	Disables HMAC-SHA1 authentication for SSH. Starting from ArubaOS 8.6.0.5, the <code>ssh disable-mac hmac-sha1</code> command disables HMAC-SHA1 authentication and enables HMAC-SHA1-96 and HMAC-SHA2-256 authentication .

Parameter	Description
hmac-sha1-96	Disables HMAC-SHA1-96 authentication for SSH. Starting from ArubaOS 8.6.0.5, <code>ssh disable-mac hmac-sha1-96</code> command disables HMAC-SHA1-96 authentication and enables HMAC-SHA1 and HMAC-SHA2-256 authentication.
hmac-sha1 hmac-sha1-96 hmac-sha1-96 hmac-sha1	Disables HMAC-SHA1 and HMAC-SHA1-96 authentication for SSH.
disable_dsa	Disables DSA authentication for SSH. Only RSA authentication is used.
mgmt-auth	Configures the authentication method for the management user. You can specify a username and password only, public key only, or both username and password and public key.
<username>	Username for SSH login.
<ip_addr>	IPv4 or IPv6 address of the remote machine.

Example

The following command configures SSH access using public key authentication only:

```
(host) [mynode] (config) #ssh mgmt-auth public-key
mgmt-user ssh-pubkey client-cert ssh-pubkey cli-admin root
```

The following command enables **AES-CBC** and disables **AES-CTR** on the SSH server:

```
(host) [md] (config) #ssh disable-ciphers aes-ctr
```

The following command enables both the cipher encryptions on the SSH server:

```
(host) [md] (config) #no ssh disable-ciphers
```

The following command disables **HMAC-SHA1-96** on the SSH server:

```
(host) [md] (config) #ssh disable-mac hmac-sha1-96
```

The following command disables **HMAC-SHA1** and **HMAC-SHA1-96** on the SSH server:

```
(host) [md] (config) #ssh disable-mac hmac-sha1 hmac-sha1-96
```

The following command disables all **dh** key exchange algorithms on the SSH server:

```
(host) [md] (config) #ssh disable-kex dh
```

Related Commands

Command	Description
show ssh	Displays the SSH configuration details.

Command History

Release	Modification
ArubaOS 8.10.0.0	Command modified to allow disabling key exchange algorithms. The key exchange algorithms can be disabled using the <code>disable-kex</code> parameter.
ArubaOS 8.7.0.0	Command modified to introduce SHA-2 authentication. The <code>hmac-sha1</code> and <code>hmac-sha1-96</code> parameters can be disabled using the <code>disable-mac</code> parameter.
ArubaOS 8.3.0.0	The following parameters are introduced to configure cipher and MAC authentication: <ul style="list-style-type: none">▪ <code>disable-ciphers</code>▪ <code>disable-mac</code>
ArubaOS 8.0.0.0	Command introduced.

sso idp-profile

```
sso idp-profile <sso_prof_name>  
  clone <source>  
  idp <string> <url>  
  no
```

Description

This command configures an SSO Identity Provider profile for use with application SSO with L2 Authentication. This command is used to configure an SSO IDP profile, which establishes the name and URL of the IDP server that Mobility Conductor uses for application SSO.

NOTE

ClearPass Policy Manager is the only device that can act as an IDP server for application SSO with an.

Parameter	Description
<sso_prof_name>	Name of the L2SSO profile.
clone <source>	Copies data from another SSO IDP profile.
idp <string> <url>	Configures the name and URL of Mobility Conductor's IDP server.
no	Deletes the command.

Example

```
(host) [mynode] (config) #sso idp-profile profile1  
idp url1 cppm128.arubanetworks.com/idp.login
```

stop-trace <macaddr>
mon-update-queue <threshold>
amon-max-batch-size <batch-size>
```

Description

This command is used to manually disconnect a client from an AP or control the denylisting of clients. If enabled, the client is not allowed to associate with any AP in the network. If the client is connected to the network when you denylist, a deauthentication message is sent to force the client to disconnect. The client is blocked for the duration specified in the virtual AP profile. The client denylist supports up to 4,000 individual client entries.

The managed device retains the client denylist in the user database, so the information is not lost if the managed device reboots. When you import or export the managed device's user database, the client denylist will be exported or imported as well.

Parameter	Description
clear-timing-stats	Clears performance monitoring stats in STM.
add-blacklist-client /add-denylist-client	MAC address of the client to be added to the denial of service list. NOTE: This parameter is available only for Managed Device.
disable-timing-stats	Disables performance monitoring in STM.
enable-timing-stats	Enables performance monitoring in STM.

Parameter	Description
kick-off-sta	When you use the kick-off-sta feature specify a client's MAC address and BSSID, the AP sends deauthorization frames to the station to disconnect it.
<macaddr>	MAC address of client to be disconnected.
<bssid>	The associated BSSID of the client to be disconnected.
purge-blacklist-client /purge-denylist-client	Clear the entire client blacklist/denylist.
purge-denylist-protected	Purge all clients from the traffic steering DoS protected list.
remove-blacklist-client/remove-denylist-client <macaddr>	Specify the MAC address of a client to remove it from the denial of service list. NOTE: This parameter is available only for Managed Device.
start-trace <macaddr>	Starts tracing probe requests and probe responses from the specified client.
stop-trace <macaddr>	Stops tracing probe requests and probe response from the specified client.
mon-update-queue <threshold>	Configures the maximum queue size for the STM monitoring updates. NOTE: This parameter is available only in Config mode on Mobility Conductor running on ArubaOS version 8.9 or earlier.

Parameter	Description
<code>amon-max-batch-size <batch-size></code>	<p>Configures the maximum number of AMONs STM will send from its queue. Any remaining AMONs in the current batch are dropped.</p> <p>NOTE: This parameter is available only in Config mode.</p>

Example

The following command blacklists/denylists a client:

```
(host) #stm add-blacklist-client /stm add-denylist-client 00:01:6C:CC:8A:6D
```

Related Commands

Command	Description
show stm	This command is used to display the deauthentication reasons and the monitoring update queue information from the station management module.

Command History

Release	Modification
ArubaOS 8.10.0.0	The <code>mon-update-queue <threshold></code> parameter was deprecated.
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Enable mode on Mobility Conductor.

support

support

Description

This command, which should be used only in conjunction with Aruba customer support, is for controller debugging purposes only. This command is used by Aruba customer support for debugging the controller. Do not use this command without the guidance of Aruba customer support.

Example

The following command allows Aruba customer support to debug the controller:

```
(host) #support
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

syscontact

syscontact <syscontact>

Description

This command configures the name of the system contact for the managed device. Use this command to enter the name of the person who acts as the system contact or administrator for the managed device. You can use a combination of numbers, letters, characters, and spaces to create the name. To include a space in the name, use quotation marks to enclose the alphanumeric string. For example, to create the system contact name Lab Technician 1, enter "Lab Technician 1" at the prompt.

To change the existing name, enter the command with a different string. The new name takes affect immediately. To unconfigure the name, enter "" at the prompt.

Parameter	Description
<syscontact>	An alphanumeric string that specifies the name of the system contact.

Example

The following command defines **LabTechnician** as the system contact name:

```
(host) [mynode] (config) #syscontact LabTechnician
```

Related Commands

Command	Description
show syscontact	Displays the system contact information.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on managed devices.

syslocation

syslocation <syslocation>

Description

This command configures the name of the system location for the managed device. Use this command to indicate the location of the managed device. You can use a combination of numbers, letters, characters, and spaces to create the name. To include a space in the name, use quotation marks to enclose the text string.

To change the existing name, enter the command with a different string. To unconfigure the location, enter "" at the prompt.

Parameter	Description
<syslocation>	An alphanumeric string that specifies the name of the system location.

Example

The following command defines **SalesLab** as the system location:

```
(host) [mynode] (config) #syslocation "Building 10, second floor, room 21E"  
syscontact LabTechnician
```

Related Commands

Command	Description
show syslocation	Displays the system location information.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

tar

```
tar clean {crash|flash|logs} | crash [kernel] | flash | logs [tech-support {no-  
controllerip  
| user <mac-address>}]
```

Description

This command creates archive files in UNIX tar file format.

Parameter	Description
clean	Removes a tar file
crash	Removes crash.tar
flash	Removes flash.tar.gz
logs	Removes logs.tar
traces	Removes traces.tar.gz
crash	Archives the crash directory to crash.tar. A crash directory must exist.
kernel	Archives the kernel crash directory to kernel_crash.tar.
flash	Archives and compresses the /flash directory to flash.tar.gz.
logs	Archives the logs directory to log.tar.
tech-support {cluster datapath no-controllerip user <mac-address>}	Optionally, technical support information can be included in the log for a specific cluster, datapath, or no controllerip or for a specific user.
serviceability	Archives the serviceability directory to serviceability.tar.7z.
traces	Archives the traces directory to traces.tar.gz

Example

The following command creates the log.tar file with technical support information:

```
(host) [mynode] (config) #tar logs tech-support
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command is available in the base operating system. The <code>ipaccess-group</code> parameter requires the PEFNG license. The <code>xsec</code> parameter requires the xSec license.	Enable or config mode on Mobility Conductor.

telnet

```
telnet <host> [port <port_num>]
  cli
  soe
```

Description

This command enables telnet to Mobility Conductor or to an AP through Mobility Conductor. Use the host and port to specify the host IP address and the port to enable telnet. This command is available only in **Enable** mode.

Use the **cli** option to enable telnet to Mobility Conductor.

Use the **soe** option to enable telnet using the SoE protocol. This allows you to remotely manage an AP directly connected to Mobility Conductor.

Parameter	Description
host	IP address of the host Mobility Conductor
port	Port number in the host
cli	Enable telnet using the CLI. Disabled
soe	Enable telnet using Serial over Ethernet (SoE). Disabled

Example

The following example enables telnet to Mobility Conductor using the CLI:

```
(host) [mynode] (config) #telnet cli
```

Related Commands

Command	Description
show telnet	Displays the telnet access status.

test

```
test jitter <probe_ip> <src_intf> <burst_count>
```

Description

This command enables jitter measurement for a specific IP address.

Parameter	Description
jitter	Test jitter probes (udp).
<probe_ip>	Specify IP address for which jitter is to be measured.
<src_intf>	Specify source interface VLAN.
<burst_count>	Specify the number of probes to be sent. 1-4000

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

threshold

```
threshold
  controlpath-cpu <value>
  controlpath-memory <value>
  datapath-cpu <value>
  no-of-APs <value>
  no-of-locals <value>
  no-of-vaps <value>
  total-tunnel-capacity <value>
  user-capacity <value>
no
```

Description

This command configures managed device capacity thresholds which, when exceeded, trigger alerts. The managed device sends a *wlsxThresholdExceeded* SNMP trap and a syslog error message when the managed device has exceeded a set percentage of the total capacity for that resource. A *wlsxThresholdCleared* SNMP trap and error message will be triggered if the resource usage drops below the threshold once again.

Parameter	Description
<code>controlpath-cpu <value></code>	Sets an alert threshold, in percentage, for the control path CPU capacity that must be exceeded before the alert is sent. Range: 0-100% Default: 80%
<code>controlpath-memory <value></code>	Sets an alert threshold, in percentage, for the control path memory consumption that must be exceeded before the alert is sent. Range: 0-100% Default: 85%
<code>datapath-cpu <value></code>	Sets an alert threshold, in percentage, for the datapath CPU capacity that must be exceeded before the alert is sent. Range: 0-100% Default: 30%
<code>no-of-APs <value></code>	The maximum number of APs that can be connected to a managed device is determined by that managed device's model type and installed licenses. Use this command to trigger an alert when the number of APs currently connected to the managed device exceeds a specific percentage of its total AP capacity. Range: 0-100% Default: 80%

Parameter	Description
<code>no-of-locals <value></code>	Sets an alert threshold, in percentage, for the Mobility Conductor's capacity to support managed devices that must be exceeded before the alert is sent. Range: 0-100% Default: 80%
<code>no-of-vaps <value></code>	The maximum number of Virtual APs that can be connected to a managed device is determined by that managed device's model type and installed licenses. Use this command to trigger an alert when the number of Virtual APs currently connected to the managed device exceeds a specific percentage of its total AP capacity. Range: 0-100% Default: 80%
<code>total-tunnel-capacity <value></code>	Sets an alert threshold, in percentage, for the managed device's tunnel capacity that must be exceeded before the alert is sent. Range: 0-100% Default: 80%
<code>user-capacity <value></code>	Sets an alert threshold, in percentage, for the managed device's user capacity that must be exceeded before the alert is sent. Range: 0-100% Default: 80%

Example

The following command configures a new alert threshold for controlpath memory consumption:

```
(host) [mynode] (config) #threshold datapath-cpu 90
```

If this threshold is exceeded then subsequently drops below the 90% threshold, the managed device would send the following two syslog error messages.

```
Mar 10 13:13:58 nanny[1393]: <399816> <ERRS> |nanny| Resource 'Control-Path Memory' has gone above 90% threshold, value : 93
Mar 10 13:16:58 nanny[1393]: <399816> <ERRS> |nanny| Resource 'Control-Path Memory' has come below 90% threshold, value : 87
```

Related Commands

Command	Description
show threshold	Displays the managed device capacity thresholds which, when exceeded, triggers alerts.

Command History

Release	Modification
ArubaOS 8.6.0.0	The <code>no-of-vaps<value></code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode

time-range

```
time-range
  absolute <name> [end <mm/dd/yyyy> <hh:mm>] [start <mm/dd/yyyy> <hh:mm>]
  no
  periodic <name>
    Daily <hh:mm> to <hh:mm>
    Friday <hh:mm> to <hh:mm>
    Monday <hh:mm> to <hh:mm>
    Saturday <hh:mm> to <hh:mm>
    Sunday <hh:mm> to <hh:mm>
    Thursday <hh:mm> to <hh:mm>
    Tuesday <hh:mm> to <hh:mm>
    Wednesday <hh:mm> to <hh:mm>
    Weekday <hh:mm> to <hh:mm>
    Weekend <hh:mm> to <hh:mm>
```

Description

This command configures time ranges. You can use time ranges when configuring session ACLs. Once you configure a time range, you can use it in multiple session ACLs.

Parameter	Description
<code>absolute <name></code>	Specifies an absolute time range, with a specific start time, end time, and date.
<code>end <mm/dd/yyyy> <hh:mm></code>	Specifies the end time of the time range.
<code>start <mm/dd/yyyy> <hh:mm></code>	Specifies the start time of the time range.
<code>no</code>	Negates any configured parameter.
<code>periodic <name></code>	Specifies a recurring time range. Select the day of the week occurrence, the start time (hh:mm), and the end time (hh:mm).

Example

The following command configures a time range for daytime working hours:

```
(host) [mynode] (config) #time-range periodic working-hours
weekday 7:30 to 18:00
```

Related Commands

Command	Description
show time-range	Displays the configured time ranges.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

time-range-profile

```
time-range-profile <profile-name>  
  absolute [start-date <abs_sdate> start-time <abs_stime>][end-date <abs_edate>  
  end-time <abs_etime>]  
  clone  
  mode {absolute|periodic}  
  no
```

Description

This command configures time range profiles. You can use time range profiles when configuring session ACLs. After you configure a time range profile, you can use it in multiple session ACLs.

Parameter	Description
<profile-name>	Name of the time range profile.
absolute	Specifies an absolute time range profile, with a specific start date, start time, end date, and end time.
start-date <abs_sdate>	Start date for the time range profile (mm/dd/yyyy).
start-time <abs_stime>	Start time for the time range profile (hh:mm).
end-date <abs_edate>	End date for the time range profile (mm/dd/yyyy).
end-time <abs_etime>	End time for the time range profile (hh:mm).
clone	Copy data from another time range profile.
mode	Time range profile mode: <ul style="list-style-type: none">▪ Absolute▪ Periodic
no	Negates any configured parameter.

Example

The following command configures a time range profile for a training class that takes place between 8:30AM and 6:00PM:

```
(host) [node] (config) #time-range-profile training absolute  
start-date <06/19/2016>  
start-time <08:30>  
end-date <06/19/2016>  
end-time <18:00>
```

tm trace

```
tm trace
  filter {category|ip-addr <ip-addr>|mac <mac>}
  loglevel
```

Description

This command is used to configure the TM traces.

Parameter	Description
filter	Specify the filter to use for the trace.
category	Specify one of the following trace category to enable or disable: <ul style="list-style-type: none">▪ all: Traces all events.▪ amon: Traces AMON events.▪ cli: Traces CLI events.▪ db_info: Traces internal DB info events.▪ db_stats: Traces internal DB stats events.▪ gsm: Traces GSM events.▪ mon: Traces MON events.▪ papi: Traces PAPI events.▪ syslog: Traces Syslog events.
ip-addr <ip-addr>	Trace only events for this IP address.
mac <mac>	Trace only events for this MAC address (contextual)
loglevel	Specify one of the following loglevel of syslogs that will be included in the trace: <ul style="list-style-type: none">▪ alert: Trace all logs equal or higher than LOG_ALERT▪ critical: Trace all logs equal or higher than LOG_CRIT▪ debug: Trace all logs equal or higher than LOG_DEBUG▪ emergency: Trace all logs equal or higher than LOG_EMERG▪ error: Trace all logs equal or higher than LOG_ERR▪ info: Trace all logs equal or higher than LOG_INFO▪ notice: Trace all logs equal or higher than LOG_NOTICE▪ warn: Trace all logs equal or higher than LOG_WARN

Example

The following command configures the maximum queue size for the TM monitoring updates.

```
(host) #tm mon update-queue 5000
```

Description

This command configures the traceoptions to monitor and log traffic flows.

Parameter	Description
chassis-manager flags	Configures the chassis manager trace options: <ul style="list-style-type: none">▪ all—Enables all chassis manager debug tracing.▪ association—Enables stack membership and association tracing.▪ debug—Enables generic chassis manager debug tracing.▪ environment-monitoring—Enables environment monitor debug tracing.▪ fru— Enables FRU reporting and management tracing.▪ interface—Enables interface debug tracing.

Parameter	Description
	<ul style="list-style-type: none"> ▪ interface-statistics—Enables packet statistics on interface tracing. ▪ ipc—Enables inter-process message exchange tracing. ▪ poe-configuration—Enables power-over-ethernet configuration tracing. ▪ poe-statistics—Enables power-over-ethernet statistics tracing. ▪ statistics-sync—Enables statistics tracing. ▪ system-statistics—Enables chassis system statistics tracing.
igmp flags	<p>Configures the IGMP trace options:</p> <ul style="list-style-type: none"> ▪ all—Enables tracing on all IGMP modules. ▪ debug—Enables internal state tracing for IGMP modules. ▪ leave—Enables IGMP leave processing tracing. ▪ query—Enables IGMP query processing tracing. ▪ report—Enables IGMP report processing tracing.
igmp-snooping flags	<p>Configures the IGMP snooping trace options:</p> <ul style="list-style-type: none"> ▪ all—Enables tracing on all igmp-snooping modules. ▪ config—Enables igmp-snooping configuration tracing. ▪ errors— Enables igmp-snooping error tracing. ▪ receive—Enables igmp-snooping PDU received (RX) tracing. ▪ transmit—Enables igmp-snooping PDU transmit (TX) tracing.
interface-manager {flags level}	<p>Configures the interface manager trace flags:</p> <ul style="list-style-type: none"> ▪ all—Enables all interface manager debug message tracing. ▪ configuration—Enables configuration debug tracing. ▪ dhcp-client—Enables dhcp client debug tracing. ▪ ethernet—Enables ethernet interface debug tracing. ▪ infrastructure—Enables infrastructure debug tracing. ▪ lACP—Enables LACP debug tracing. ▪ loopback—Enables loopback interface debug tracing.

Parameter	Description
	<ul style="list-style-type: none"> ▪ mgmt—Enables management interface debug tracing. ▪ oam—Enables OAM debug tracing. ▪ port-channel—Enables port-channel debug tracing. ▪ port-mirroring—Enables port mirroring debug tracing. ▪ system-information—Enables system debug messages tracing. ▪ tunnel—Enables tunnel interface debug tracing. ▪ vlan—Enables vlan interface debug tracing. <p>Configures the level for interface manager tracing:</p> <ul style="list-style-type: none"> ▪ debug—Debug messages ▪ error—Error messages ▪ verbose—Verbose debug messages
<pre>layer2-forwarding {flags level size}</pre>	<p>Configures the layer2 forwarding trace flags:</p> <ul style="list-style-type: none"> ▪ all—Enables tracing on all switching modules. ▪ config—Enables config module tracing. ▪ fdb—Enables forwarding database module tracing. ▪ hsl—Enables HSL module tracing. ▪ interface—Enables interface module tracing. ▪ ipc—Enables IPC tracing. ▪ learning—Enables learning module tracing. ▪ nexthop—Enables nexthop module tracing. ▪ port-loop—Enables Port loop protect Protocol tracing. ▪ sysinfo—Enables sysinfo module tracing. ▪ task—Enables task tracing. ▪ timer—Enables task timer tracing. ▪ tunneled-node—Enables tunneled-node module tracing. ▪ vlan—Enables vlan module tracing. ▪ vlan-assignment—Enables VLAN assignment module tracing. ▪ vlan-port—Enables VLAN port module tracing. <p>Configures the layer2 forwarding tracing levels:</p> <ul style="list-style-type: none"> ▪ debug—Debug messages ▪ error—Error messages ▪ informational—Informational messages <p>Configures the maximum size for layer2 forwarding trace file in MB.</p>
<pre>lldp flags</pre>	<p>Configures the LLDP trace options:</p>

Parameter	Description
	<ul style="list-style-type: none"> ▪ all—Enables tracing on all lldp modules. ▪ errors—Enables lldp error tracing. ▪ receive—Enables lldp PDU receive (RX) tracing. ▪ system-state—Enables lldp system-state tracing. ▪ transmit—Enables lldp PDU transmit (TX) tracing.
<pre>mstp {flags port}</pre>	<p>Configures the MSTP trace flags and trace port:</p> <ul style="list-style-type: none"> ▪ all—Enables tracing on all mstp modules ▪ config—Enables mstp config tracing. ▪ debug—Enables mstp debug tracing. ▪ port-information—Enables mstp port information tracing. ▪ received-bpdu-all—Enables mstp received bpdu tracing. ▪ role-selection—Enables mstp role selection tracing. ▪ sent-bpdu-all—Enables mstp sent bpdu tracing. ▪ state-machine-changes—Enables mstp state machine change tracing. ▪ system—Enables mstp system tracing. ▪ topology-change—Enables mstp topology change tracing.
<pre>ospf flags</pre>	<p>Configures the OSPF trace options:</p> <ul style="list-style-type: none"> ▪ all—Enables tracing for all ospf events. ▪ cnf—Enables configuration events tracing. ▪ db—Enables database operations tracing. ▪ dd—Enables database description packets tracing. ▪ debug—Enables internal debug tracing. ▪ dr-elect—Enables designated router election tracing. ▪ flood—Enables linkstate flooding tracing. ▪ hello—Enables tracing for hello packets. ▪ lsa—Enables link state advertisement packets tracing. ▪ lsr—Enables link state request packets tracing. ▪ lsu—Enables link state update packets tracing. ▪ msm—Enables msm events tracing. ▪ pkt-all—Enables tracing for all packets. ▪ spf—Enables SPF operations tracing. ▪ state—Enables interface, neighbor, area changes tracing.

Parameter	Description
<p>pim flags</p>	<p>Configures PIM sparse mode trace options:</p> <ul style="list-style-type: none"> ▪ adjacency—Enables pim sparse mode adjacency tracing. ▪ all—Enables tracing on all pim sparse mode modules. ▪ debug—Enables internal state tracing for pim sparse mode modules. ▪ jp-asserts—Enables pim sparse mode join-prune/assert tracing. ▪ register—Enables pim sparse mode register tracing. ▪ route—Enables pim sparse mode route tracing. ▪ state—Enables pim sparse mode state tracing.
<p>rmon {flags level size}</p>	<p>Configures the RMON trace flags:</p> <ul style="list-style-type: none"> ▪ alarm—Enables rmon alarm module debug tracing. ▪ all—Enables rmon all module debug tracing. ▪ cli—Enables rmon CLI module debug tracing. ▪ event—Enables rmon event debug tracing. ▪ history—Enables rmon history module debug tracing. ▪ ifstat—Enables rmon interface statistics debug tracing. ▪ log—Enables rmon log debug tracing. ▪ snmp—Enables rmon SNMP module debug tracing. <p>Configures the RMON tracing levels:</p> <ul style="list-style-type: none"> ▪ alert—Alert messages ▪ critical—Critical messages ▪ debugging—Debug messages ▪ emergency—Emergency messages ▪ errors—Error messages ▪ informational—Informational messages ▪ notice—Notification messages ▪ warning—Warning messages <p>Configures the maximum size for RMON trace file in MB.</p>
<p>routing flags</p>	<p>Configures the layer3 manager trace options:</p> <ul style="list-style-type: none"> ▪ all—Enables tracing on all layer3 manager events. ▪ arp—Enables arp module tracing. ▪ configuration—Enables layer3 configuration processing tracing.

Parameter	Description
	<ul style="list-style-type: none"> ▪ event—Enables layer3 manager system events tracing. ▪ interface—Enables layer3 manager interface events tracing. ▪ route—Enables route table updates tracing.
<pre>stack-manager {flags level}</pre>	<p>Configures the stack manager trace flags:</p> <ul style="list-style-type: none"> ▪ adjacency—Enables stack-manager adjacency tracing. ▪ all—Enables tracing for all stack-manager modules. ▪ asp—Enables aruba stacking protocol tracing. ▪ configuration—Enables tracing for configuration of stack-manager. ▪ primary-election—Enables tracing for primary election. ▪ route—Enables stack-manager route calculations tracing. ▪ system—Enables tracing for stack-manager interaction with other components. ▪ webui—Enables tracing for stack-manager interaction with WebUI. <p>Configures the stack manager tracing level:</p> <ul style="list-style-type: none"> ▪ alert—Alert messages ▪ critical—Critical messages ▪ debugging—Debug messages ▪ emergency—Emergency messages ▪ errors—Error messages ▪ informational—Informational messages ▪ notice—Notification messages ▪ warning—Warning messages

Example

The following command enables tracing on all IGMP modules:

```
(host) [mynode] (config) #traceoptions igmp flags all
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

tracepath

tracepath <global-address>

Description

Traces the path of an IPv6 host and identifies points of failure in your IPv6 network.

Parameter	Description
<global-address>	The IPv6 global address of the host.

Example

The following command traces the path of the specified IPv6 host.

```
(host) [mynode] (config) #tracepath 2005:d81f:f9f0:1001::14
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

traceroute

```
traceroute <ipaddr>  
  source
```

Description

Trace the route to the specified IP address.

Syntax

Parameter	Description
<ipaddr>	The destination IP address.
source <ipaddr>	Sets the source IP address through which packets are sent for tracing route.

Usage Guidelines

Use this command to identify points of failure in your network.

Example

The following command traces the route to the device identified by the IP address 10.1.2.3.

```
(host) [mynode] (config) #traceroute 10.1.2.3
```

Command History

tunnel-group

```
tunnel-group <tungrpname>  
  mode {l2|l3}  
  no  
  preemptive-failover  
  tunnel <tunnel-id>
```

Description

This command creates a tunnel-group to group a set of tunnels. Use this command to provide redundancy for L3 GRE tunnels. This feature enables automatic redirection of the user traffic to a standby tunnel when the primary tunnel goes down.

To enable L3 GRE tunnel group, you must:

- Configure a tunnel-group to group a set of tunnels.
- Enable tunnel keepalives on all the tunnel interfaces assigned to the tunnel-group, and
- Configure the session ACL with the tunnel-group as the redirect destination.

To enable L2 GRE tunnel group, you must:

- Configure the member tunnel and add them to the appropriate VLAN.
- Enable tunnel keepalives on the tunnel interface.
- Configure the tunnel-group and set the group type to L2, and
- Add the member tunnel to the group

You can configure up to 32 tunnel-groups on a with a maximum of 5 tunnels in each tunnel-group.

Parameter	Description
mode {l2 l3}	Set the type of tunnel-group. Default: l3
no	Negates any parameter configured.
preemptive-failover	When enabled, this option automatically redirects the traffic upon detecting an active tunnel with a higher precedence in the tunnel-group. When disabled, the traffic gets redirected to a higher precedence tunnel only when the tunnel carrying the traffic fails. Default: Enabled
tunnel <tunnel-id>	Adds the specified tunnel ID to the tunnel group. Range: 1-16777215.

Example

The following set of commands create a tunnel-group with tunnel IDs 10 and 20 as the members:

```
(host) [mynode] (config) #tunnel-group tgroup1
(host) [mynode] (config-tunnel-group) # mode 13
(host) [mynode] (config-tunnel-group) # tunnel 10
(host) [mynode] (config-tunnel-group) # tunnel 20
(host) [mynode] (config-tunnel-group) #preemptive-failover
```

tunnel-loop-prevention

tunnel-loop-prevention

Description

This command prevents prevent forwarding loops between tunneled nodes on the managed device.

To allow a tunneled node-connected machine to communicate with another managed device that is a connected client on the same subnet, you must enable **ip local-proxy-arp**.

Example

The following command prevents tunneled node forwarding:

```
(host) [mynode] (config) #tunnel-loop-prevention
```

Related Commands

Command	Description
show tunneled-node	Displays the wired tunneled node configuration details, the state of the tunneled node, and lists all the tunneled nodes in the database.

Command History

tunneled-node-address

tunneled-node-address <tnode-ip-address>

Description

This command configures the IP address of a tunneled node server. An Aruba managed device can operate as a Wi-Fi managed device, terminating GRE tunnels from tunneled node switches. As a Wi-Fi managed device, the managed device does not perform full Wi-Fi switching functions. Instead, it accepts traffic from ports designated as tunneled node ports, packages this traffic inside a GRE tunnel, and forwards the traffic back to a central managed device for processing.

Parameter	Description
<tnode-ip-address>	IP address of the managed device. This is the loopback or IP address of the managed device acting as a tunneled node managed device.

Example

The following command configures the address of a managed device for tunneled nodes:

```
(host) [mynode] (config) #tunneled-node-address 192.168.1.245
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

tunnel-node-mtu

tunnel-node-mtu <mtu>

Description

This command configures the MTU of a tunneled node. An Aruba managed device can operate as a Wi-Fi managed device, terminating GRE tunnels from tunneled node switches. As a Wi-Fi managed device, the managed device does not perform full Wi-Fi switching functions. Instead, it accepts traffic from ports designated as tunneled node ports, packages this traffic inside a GRE tunnel, and forwards the traffic back to a central managed device for processing.

This command does not take effect when the tunnel node client is an switch.

Parameter	Description
tnode-mtu	Value of the MTU for the tunneled nodes Range: 1024 to 9216

Example

The following command configures the MTU of a managed device for tunneled nodes:

```
(host) [mynode] (config) #tunnel-node-mtu 1030
```

Command History

uap-blacklist / uap-denylist

```
uap-blacklist / uap-denylist
  add mac-address <address> description <description>
  del mac-address <address>
  modify mac-address <address> description <description>
  purge
```

Description

This command configures a Unified AP (UAP) blacklist/denylist database entry. You can add, delete, or modify AP MAC addresses and description to the database. If you enable the blacklist/denylist policy in the AP deploy profile, the policy is applied to the APs included in this list. You can also purge this database from the device.

Parameter	Description
<code>add mac-address <address> description <description></code>	Adds the specified AP MAC address to the blacklist/denylist database.
<code>del mac-address <address></code>	Deletes the specified AP MAC address from the blacklist/denylist database.
<code>modify mac-address <address> description <description></code>	Modifies the details of an existing MAC address entry in the blacklist/denylist database.
<code>purge</code>	Purges the blacklist/denylist database.

Example

The following command adds the 11:11:11:11:11:11 MAC address entry to the UAP blacklist/denylist database:

```
(host) [mynode] #uap-blacklist / uap-denylist add mac-address
11:11:11:11:11:11 description AP-203H
The following command modifies the description of the 11:11:11:11:11:11 MAC
address entry from AP-203H to AP-203R in the UAP blacklist/denylist
database:
```

Related Commands

Command	Description
ap deploy-profile	The blacklist/denylist policy when enabled in the AP deploy profile, applies the policy to the UAP blacklist/denylist database entries.
show uap-blacklist/show uap-denylist	This command displays the UAP blacklist/denylist database entries.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.2.0.0	Command introduced.

Description

This command configures the various UCC Application Layer Gateways (ALGs). The UCC ALGs must be configured from the **/mm** node hierarchy of Mobility Conductor. All the ALGs are enabled by default.

Parameter	Description
custom-sip	<p>Configures the custom SIP ALG. The ALG is enabled by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ app-name - Configure an application name. ▪ custom_sip_port - Configure the custom SIP port number. ▪ enable - Enable the custom SIP ALG. ▪ key - Configure the user-agent key-name. ▪ no - Remove or negate a parameter. ▪ priority- Configure the DSCP value for the video or voice session. <p>Range: Priority voice: 0-63 and priority video: 0-63</p>
facetime	<p>Configures the Apple® FaceTime ALG. The ALG is enabled by default. The DSCP value for the video session is 34 by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ enable- Enable the Apple Facetime ALG on the Mobility Conductor. ▪ no- Remove or negate a parameter. ▪ priority- The DSCP value for the video session. <p>Range: Priority video: 0-63 Default: Priority video: 34</p>
h323	<p>Configures the H.323 ALG. The ALG is enabled by default. The DSCP value for the voice session is 46 by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ enable- Enable the H.323 ALG on the Mobility Conductor. ▪ no- Remove or negate a parameter. ▪ priority- The DSCP value for the voice session. <p>Range: Priority voice: 0-63 Default: Priority voice: 46</p>
ich	<p>Configures the intelligent call handling. The setting is enabled by default. The Channel Utilization Threshold is 90 by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ channel-utilization-threshold-The maximum limit for the channel utilization. ▪ enable-Enable intelligent call handling on the Mobility Conductor. ▪ no-Remove or negate a parameter. <p>Range: Channel-utilization-threshold: 50-95 Default: Channel-utilization-threshold: 90</p>

Parameter	Description
jabber	<p>Configures the Cisco® Jabber ALG. The ALG is enabled by default. Enter the Cisco Unified Communication Manager IM & Presence server IP. The DSCP values for the voice, video, and app-sharing sessions are 46, 34, and 34, respectively, by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>enable</code>–Enable Jabber ALG on the Mobility Conductor. ▪ <code>no</code>–Remove or negate a parameter. ▪ <code>priority</code>–The DSCP value for voice, video, and app-sharing sessions. ▪ <code>server-ip</code>–Jabber server IP. <p>Range: App-sharing, video, and voice: 0-63 Default: App-sharing: 34, video: 34, and voice: 46</p>
noe	<p>Configures the Alcatel-Lucent® New Office Environment (NOE) ALG. The ALG is enabled by default. The DSCP value for the voice session is 46 by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>enable</code>– Enable the NOE ALG on the Mobility Conductor. ▪ <code>no</code>– Remove or negate a parameter. ▪ <code>priority</code>– The DSCP value for the voice session. <p>Range: Priority voice: 0-63 Default: Priority voice: 46</p>
rtpa-config	<p>Configures the real-time analysis of VoIP calls including upstream real-time analysis. The setting is enabled by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>enable</code>– Enable Real-Time Analysis of VoIP calls. ▪ <code>no</code>– Remove or negate a parameter. ▪ <code>upstream</code>–Enable upstream Real-Time Analysis of VoIP calls.
sccp	<p>Configures the Cisco Skinny Client Control Protocol (SCCP) ALG. The ALG is enabled by default. The DSCP value for the voice session is 46 by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>enable</code>– Enable the SCCP ALG on the Mobility Conductor. ▪ <code>no</code>– Remove or negate a parameter. ▪ <code>priority</code>– The DSCP value for the voice session. <p>Range: Priority voice: 0-63 Default: Priority voice: 46</p>
session-idle-timeout	<p>Configures the UCC session idle timeout. On configuring this parameter, if the voice session is idle for the configured period, UCM aborts the session on the managed device due to inactivity. The default value is 35. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>no</code>– Remove or negate a parameter.

Parameter	Description
	<ul style="list-style-type: none"> ▪ <code>value</code>- Configure UCC session idle timeout in seconds. <p>Range: Value: 35-250 Default: Value: 35</p>
sip	<p>Configures the Session Initiation Protocol (SIP) ALG. The ALG is enabled by default. You can enable the SIP Midcall request timeout and RTCP inactivity settings. The DSCP values for the voice and video sessions are 46 and 34, respectively, by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>enable</code>-Enable SIP ALG on the Mobility Conductor. ▪ <code>midcall-req-timeout</code>-Enable SIP Midcall request timeout. ▪ <code>no</code>-Remove or negate a parameter. ▪ <code>priority</code>-The DSCP value for voice and video sessions. ▪ <code>rtcp-inactivity</code>-Enable Real-Time Control Protocol inactivity. <p>Range: Video and voice: 0-63 Default: Video: 34 and voice: 46</p>
skype4b	<p>Configures the Microsoft® Lync/Skype for Business ALG. The ALG is enabled by default. You can set the Skype for Business SDN listen protocol over HTTP or HTTPS. Based on the SDN listen protocol configuration, Mobility Conductor accepts either HTTP or HTTPS messages from the Skype for Business SDN manager. The DSCP values for the voice, video, and app-sharing sessions are 46, 34, and 34, respectively, by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ <code>enable</code>-Enable Skype for Business ALG on the Mobility Conductor. ▪ <code>no</code>-Remove or negate a parameter. ▪ <code>priority</code>-The DSCP value for voice, video, and app-sharing sessions. ▪ <code>sdn</code>-Skype for Business SDN listen protocol. The default Skype for Business SDN API listen port is 32000. <p>Range: app-sharing, video, and voice: 0-63 Default: app-sharing: 34, video: 34, and voice: 46</p>
teams	<p>Configure the Microsoft Teams ALG. The ALG is enabled by default.</p> <ul style="list-style-type: none"> ▪ <code>enable</code>-Enable the Microsoft Teams ALG on the Mobility Conductor. ▪ <code>no</code>-Remove or negate a parameter. ▪ <code>priority</code>-The DSCP value for video and voice.

Parameter	Description
vocera	<p>Configure the Vocera ALG. The ALG is enabled by default. The DSCP value for the voice session is 46 by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ enable- Enable the Vocera ALG on the Mobility Conductor. ▪ no- Remove or negate a parameter. ▪ priority- The DSCP value for the voice session. <p>Range: Priority voice: 0-63 Default: Priority voice: 46</p>
webrtc	<p>Configure the WebRTC ALG. The ALG is enabled by default. This parameter has the following sub-parameters:</p> <ul style="list-style-type: none"> ▪ enable- Enable the WebRTC ALG on the Mobility Conductor. ▪ no- Remove or negate a parameter. ▪ priority- The DSCP value for the video or voice session. <p>Range: Priority video: 0-63 priority voice: 0-63 Default: Priority voice: 46</p>
wificalling	<p>Configures the Wi-Fi Calling. Wi-Fi Calling is enabled by default. The DSCP value for the voice session is 46 by default.</p> <ul style="list-style-type: none"> ▪ dns-pattern- Configure the DNS pattern for the carrier. A maximum of 10 DNS patterns can be configured. DNS patterns for known carriers are configured by default. Default built-in patterns are: <ul style="list-style-type: none"> - 3 HK - wlan.three.com.hk - ATT - epdg.epc.att.net - Rogers - epdg.epc.mnc720.mcc302.pub.3gppnetwork.org - SmarTone - epdg.epc.mnc006.mcc454.pub.3gppnetwork.org - Sprint - primgw.vowifi2.spcsdns.net - T-Mobile - ss.epdg.epc.mnc260.mcc310.pub.3gppnetwork.org - Verizon - wo.vzww.com <p>If the ePDG FQDN of the carrier does not match with the default patterns, use this option to configure the DNS pattern for the carrier.</p> <p>NOTE: The DNS IP address that Mobility Conductor learns for Wi-Fi Calling age out automatically, if there was no DNS query or response matching that IP for more than seven days.</p> ▪ service-provider- Add the service provider name for enhanced visibility. ▪ enable- Enable the Wi-Fi calling ALG on the Mobility Conductor. ▪ no- Remove or negate a parameter.

Parameter	Description
	<ul style="list-style-type: none"> ▪ priority- The DSCP value for the voice session. Range: Priority voice: 0-62 Default: Priority voice: 46

Examples

The following commands enables Wi-Fi calling on Mobility Conductor:

```
(host) [mm] (config) #ucc wificalling
(host) ^[mm] (WiFiCalling Configuration) #enable
The following command displays the UCC client MAC and IP address table. The
ucc tables command should be executed from the enable mode:
(host) [mynode] #ucc tables
-----
UCC Client MAC table
-----
Client (MAC)      Client (IP)      Type      ALG
-----
68:17:29:9f:b6:77  10.15.88.234    Client    Jabber/xmpp/SIP
-----
UCC Client IP table
-----
Client (MAC)      Client (IP)      Type      ALG
-----
00:0b:86:8f:d6:b7  10.15.16.50     Server    SIP
00:0b:86:8f:d6:b7  10.15.16.30     Server    Jabber
68:17:29:9f:b6:77  10.15.88.234    Client    Jabber/xmpp/SIP
-----
```

Description

This command upgrades the managed devices with the respective options provided in the input, like using different protocol options as well as loading at different node levels and paths, and also can upgrade the single managed device based on the MAC address of the device. This command is internal or hidden.

Parameter	Description
copy configured-fileserver	Copies the configured file server options like file, force-file, version, and force-version.
copy fileserver	Specify the file server details like, scp, ftp, tftp.
copy-reboot configured-fileserver	Reboots the managed devices after successful upgrade of the respective image using configured-file server options like file, force-file, version and force-version.
copy-reboot fileserver	Selects the type of supported servers like, ftp, scp, tftp and reboots the managed device post upgrade.
reboot	Reboots the managed device.

Parameter	Description
ftp	Used for mentioning FTP server.
scp	Used for mentioning SCP server.
tftp	Used for mentioning TFTP server.
file	Used for mentioning TFTP server.
force-file	Exact name of the image or image file.
force-version	Used to force the standard image name and is based on the platform type and version running on the managed device.
version	Image version and standard name based on platform type generated to load the image.

Example

The following command installs **ArubaOS_72xx_8.0.0.0-svcs-ctrl_55579** image from the configured file server on the network for a managed device with a MAC address **00:1a:1e:01:b0:b0** in partition 0:

```
(host) [mynode] #upgrade internal managed-devices copy configured-fileserver
file ArubaOS_72xx_8.0.0.0-svcs-ctrl_55579 list 00:1a:1e:01:b0:b0 partition 0
```

Description

This command upgrades the managed devices with the respective options provided in the input, like using different protocol options as well as loading at different node levels and paths, and also can upgrade the single managed device based on the MAC address of the device.

This command can only be issued on the /md node or a specific node. This command is ignored if issued on the /mynode node.

Parameter	Description
ca-bundle update	Upgrades the trusted CA certificates of managed devices.
ca-bundle reset	Resets the trusted CA certificates of managed devices.
ca-bundle download url <url>	(Optional) CA certificates will be downloaded from the specified URL. If the URL is not mentioned, the certificates will be downloaded from Activate. NOTE: The URL should begin with either http or https.
all	Upgrades/ resets the trusted CA certificates of all managed devices

Parameter	Description
path <node-path>	Upgrades/ resets the trusted CA certificates of managed devices under a specific node path. The node path must begin with /.
single <mac>	Upgrades/ resets the trusted CA certificates of a specific managed device.
copy configured-fileserver	Copies the configured file server options like file, force-file, version, and force-version.
copy fileserver	Specify the file server details like, scp, ftp, tftp.
copy-no-change-default-boot configured-fileserver	Copies upgrade image to managed devices without changing default boot using configured file server options like file, force-file, version, and force-version.
copy-no-change-default-boot fileserver	Copies upgrade image to managed devices without changing default boot using file server details like, scp, ftp, tftp.
copy-reboot configured-fileserver	Reboots the managed devices after successful upgrade of the respective image using configured-file server options like file, force-file, version and force-version.
copy-reboot fileserver	Selects the type of supported servers like, ftp, scp, tftp and reboots the managed device post upgrade
reboot	Reboots the managed device.
all	Copies/ upgrades image to all managed devices under the respective node path

Parameter	Description
path	Copies/ upgrades image under specific node path and all the managed devices under this node path target node and make them as target list.
single	Copies/ upgrades image to the specific managed device based on MAC address under the respective node-path.
ftp	Used for mentioning FTP server.
scp	Used for mentioning SCP server.
tftp	Used for mentioning TFTP server.
file	Exact name of the image or image file.
force-file	Forcing the exact image name on the file-server by ignoring the existing file or image on the managed device..
force-my-version	Used to force the master standard image name and is based on the platform type and version running on the managed device is ignored.
force-version	Used to force the standard image name and is based on the platform type and version running on the managed device.
my-version	Master Image version and standard name based on platform type generated to load the image.
version	Image version and standard name based on platform type generated to load the image.
schedule <year> <month> <day> <hour> <min> <sec>	Schedule the upgrade to occur at specified date and time.

Parameter	Description
partition	Specify the partition for the upgrade as 0 or 1.

Example

The following command schedules the upgrade of ArubaOS image on partition 0 of a single managed device with MAC address 1a:2b:3c:4d:5e:6f under the **/md** node by using an ArubaOS image from an FTP file server on the network. The upgrade is scheduled to occur at 10:30:15 AM on the 11th of December 2018.

```
(host) [md] #upgrade managed-devices copy fileserver ftp
191.1.2.3 anonymous . file ArubaOS_70xx_8.4.0.0_68198 single
1a:2b:3c:4d:5e:6f partition 0 schedule 2018 12 11 10 30 153
```

upgrade cancel-schedule

upgrade cancel-schedule

```
<year> <month> <day> <hour> <min> <sec> {all|path <node-path>|single <mac-addr>}
```

Description

This command cancels an already scheduled upgrade of the managed devices.

Parameter	Description
<year>	Specify the scheduled year in YYYY format.
<month>	Specify the scheduled month in MM format. Example: Specify 10 for October.
<day>	Specify the scheduled day of the month.
<hour>	Specify the scheduled hour in 24-hour format.
<min>	Specify the scheduled minute.
<sec>	Specify the scheduled second.
all	Cancels the scheduled upgrade on all managed devices. Target managed devices will be all managed devices under the node path.
path	Cancels the scheduled upgrade on all managed devices under the specified node path. Target managed devices will be the managed devices under the specified node path.
single <mac-addr>	Cancels the scheduled upgrade on specified managed device. Specify the MAC address of the target managed device. The managed device should be under the current node path.

Example

The following command cancels the scheduled upgrade on all managed devices:

```
(host) [mynode] #upgrade cancel-schedule 2018 12 01 23 59 59 all
```

upgrade reschedule

upgrade reschedule

```
from <from-year> <from-month> <from-day> <from-hour> <from-min> <from-sec> to  
<to-year> <to-month> <to-day> <to-hour> <to-min> <to-sec> {all|path <node-  
path>|single <mac-addr>}
```

Description

This command reschedules the existing scheduled upgrade of the managed devices.

Parameter	Description
from	Specify the original schedule.
<from-year>	Specify the originally scheduled year in YYYY format.
<from-month>	Specify the originally scheduled month in MM format. Example: Specify 10 for October.
<from-day>	Specify the originally scheduled day of the month.
<from-hour>	Specify the originally scheduled hour in 24-hour format.
<from-min>	Specify the originally scheduled minute.
<from-sec>	Specify the originally scheduled second.
to	Specify the new schedule.
<to-year>	Specify the new year in YYYY format.
<to-month>	Specify the new month in MM format. Example: Specify 10 for October.
<to-day>	Specify the new day.
<to-hour>	Specify the new hour in 24-hour format.
<to-min>	Specify the new minute.
<to-sec>	Specify the new second.
all	Reschedule the scheduled upgrade on all managed devices. Target managed devices will be all managed devices under the node path.
path	Reschedule the scheduled upgrade on all managed devices under the specified node path. Target managed devices will be the managed devices under the specified node path.

Parameter	Description
<code>single <mac-addr></code>	Reschedule the scheduled upgrade on specified managed device. Specify the MAC address of the target managed device. The managed device should be under the current node path.

Example

The following command reschedules the scheduled upgrade on all managed devices:

```
(host) [mynode] #upgrade reschedule from 2018 11 30 23 59 59 to 2018 12 25 12 30 00 all
```

Command History

Release	Description
ArubaOS 8.10.0.0	The <code>from</code> parameter is deprecated.
ArubaOS 8.4.0.0	Command introduced.

upgrade-pkg

```
upgrade-pkg
  activate <packagename>
  copy
    ftp: <ftphost> <username> <filename> flash: <destfilename>
    scp: <scphost> <username> <filename> flash: <destfilename>
    tftp: <tftphost> flash: <destfilename>
  remove
```

Description

This command upgrades the service module on Mobility Conductor.

Parameter	Description
activate <packagename>	Install and activate the service package.
copy	Download a service package through an FTP, SCP, or TFTP server.
remove	Delete a service package.

Example

This command upgrades the service module on Mobility Conductor.

```
(host) [mynode] #upgrade-pkg copy ftp: 192.0.2.22 anonymous
ArubaOS_MM_8.0.0.0-svcs-ctrl_appRF_55579 flash: ArubaOS_MM_8.0.0.0-svcs-
ctrl_appRF_55579
(host) [mynode] #upgrade-pkg activate ArubaOS_MM_8.0.0.0-svcs-ctrl_appRF_
55579
```

This command removes the service module on Mobility Conductor.

```
(host) [mynode] #upgrade-pkg remove ArubaOS_MM_8.0.0.0-svcs-ctrl_appRF_55579
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

upgrade-profile

```
upgrade-profile
  download_from_mm
  filepath
  no
  password
  protocol
  serverip
  username
  serverip
  serveraddr
```

Description

This command is used to configure the upgrade profile and can be executed only from the **/md** node-hierarchy.

Parameter	Description
download_from_mm	Download Image from MM-fileserver
filepath	File path to the location on the image server where the image file(s) reside.
no	Delete command
password	If you selected the FTP or SCP protocol for the Protocol type, enter the password that Mobility Conductor will use to connect to the image server.
protocol	Specify the protocol used to send the software upgrade from the image server to the managed device. <ul style="list-style-type: none">▪ TFTP▪ FTP▪ SCP
username <username>	If you specified FTP or SCP for the protocol parameter field, enter the user name that Mobility Conductor uses to connect to the image server.
serverip	Specify the IPv4 address of the image server. This parameter is only used by managed devices running versions prior to ArubaOS 8.2 and accepts only IPv4 address. NOTE: For FTP or SCP protocol, specify the username and password.

Parameter	Description
serveraddr	Specify the IPv4 or IPv6 address of the image server. This parameter is only used by managed devices running ArubaOS 8.2. NOTE: For FTP or SCP protocol, specify the username and password.

Example

The following command is used to upgrade managed devices:

```
(host) [md] #upgrade-profile
(host) [md] (Upgrade Profile) #serveraddr 2000:192:168:28::59
(host) [md] (Upgrade Profile) #username root
(host) [md] (Upgrade Profile) #password root123
(host) [md] (Upgrade Profile) #filepath Builds
(host) [md] (Upgrade Profile) #protocol scp
```

Command History

Release	Modification
ArubaOS 8.8.0.0	The download_from_mm parameter was added.
ArubaOS 8.2.0.0	The serveraddr parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode

uplink

```
uplink
  cellular
    active
    apn <APN-Profile-Pid> <APN-name>
    backup-link
    data-limit
    frequency-band
    gps
    network-mode
    plmn
    priority
    profile
    reclassify
    speed
    uplink-id
    weight
  health-check ip {<fqdn>|<ip>}
  load-balance
    mode {hash-based|round-robin|session-count|uplink utilization}
    threshold-limits
      session-count-percent <sess_percent>
  wired
    priority <prior>
    vlan <id> uplink-id {link1|link2|link3|link4} mode hub
```

Description

Use this command to manage and configure the uplink network connection.

A managed device that supports multiple 3G cellular uplink ports in addition to their standard wired ports provides redundancy in the event of connection failure. However, at a time, only one cellular uplink is supported irrespective of many plugged-in. The **uplink health-check** configuration is required for WAN health based uplink-failover.

The uplink manager is disabled by default.

If **uplink load-balance** is enabled (active-active operation), and the device fails-over to cellular uplink because all wired uplink ports became unusable (unreachable or interface is down) then uplink load-balancing gets disabled automatically. This is because cellular uplink never participates in load-balancing of WAN traffic. Once any wired uplink port becomes usable again, cellular is disconnected and load-balancing get enabled again.

The uplink manager and load-balancing features are enabled automatically when you configure the cellular or wired uplinks.

To view the health status of an uplink on a services or managed device, issue the command [show uplink](#) in the managed device CLI. For a managed device, the health status of its uplink connections are also displayed in the **Status** section of the **Dashboard > WAN** page of the managed device WebUI.

Parameter	Description
cellular	Set the cellular uplink configuration.
active	Switch to SIM1 or SIM2 and connect to it. It will be also Boot time SIM slot select(SIM1 or SIM2).(First to connect LTE during boot or init) .
apn <APN-Profile-Pid> <APN-Name>	Specify the AP name of the cellular uplink and connection ID in modem dial string.
backup-link	Mark cellular uplink as a hot-standby uplink.
data-limit <data-limit-val>	Specify the data limit value in MB for cellular connection.
frequency-band	Specify the frequency-band configuration as 3G band or 4G band and specify Tx.Rx speed.
gps	Enable GPS.
network-mode	Specify the network mode as 3G, Auto, Custom, or LTE. By default, auto mode is set. Custom mode is not used for CLI configuration.
plmn <plmn-id>	plmn value for same carrier
priority <prior>	Set the priority of the cellular uplink. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link. Configuring the cellular link with a higher priority than your wired link priority will set your cellular link as the primary link. 1-255
profile	Cellular interface profile.
reclassify	Re-init cellular uplink connection - Reboot not needed.
speed <cellular_speed>	Configure maximum cellular uplink speed in Mbps. 1-1000

Parameter	Description
uplink-id <name>	Identifier(name) for cellular uplink.
weight <cellular_weight>	Weight of this cellular uplink (used in load-balancing) 1-100
load-balance	Load-balance configuration.
mode hash-based round-robin session-count uplink-utilization	Choose one of the following load balancing modes: <ul style="list-style-type: none"> ▪ Hash based: Hash-based load balancing uses information from the packets being sent, (e.g. the source IP address, destination IP address, protocol and port numbers to determine how to load balance that traffic) ▪ Round Robin: Traffic is equally distributed to all the active uplinks ▪ Session Count: Traffic is balanced between the uplink ports based on the number of sessions managed by each link. The session-distribution is guided by uplink load-balance threshold-limits session-count <> percentage. ▪ uplink-utilization: Use available uplink capacity to load-balance.
threshold-limits	Define threshold limits for load balancing.
session-count-percent <sess_perc>	Specify the maximum percentage of total sessions that can be managed by any active uplink. The default % is equally distributed among the number of wired uplink ports present. That is: <ul style="list-style-type: none"> ▪ For 4 uplink ports- 25% ▪ For 3 uplink ports- 33% ▪ For 2 uplink ports- 50% ▪ For 1 uplink port- 100%

Parameter	Description
threshold-limits	Set threshold limits for load balancing. The valid value is session count percentage.
health-check {ip {<fqdn> <ip>}}	The <code>health-check</code> parameter is introduced to monitor the availability and quality of the connection to a master/conductor managed device with the specified FQDN or IP address.
wired	Define the wired uplink configuration.
priority <prior>	Define the default priority for wired uplinks. 1-255 200.
vlan <id> uplink-id {link1 link2 link3 link4}	Define the VLAN ID of the uplink VLAN. A maximum of four wired VLANs can be defined. 1-4094
mode	Specify the operating mode of the uplink.
hub	Specify that this uplink accepts overlay connection from spoke devices.

```

Description

This command configures a user role.

Every client in a user-centric network is associated with a user role. All wireless clients start in an initial role. From the initial role, clients can be placed into other user roles as they pass authentication.

Parameter	Description
<name>	Role name
access-list	Type of ACL to be applied: eth: Ethertype ACL, configured with the <code>ip access-list eth</code> command.

Parameter	Description
	<p>mac: MAC ACL, configured with the <code>ip access-list mac</code> command.</p> <p>session: Session ACL, configured with the <code>ip access-list session</code> command.</p>
<acl>	Name of the configured ACL.
ap-group	(Optional) AP group to which this ACL applies.
position	<p>(Optional) Position of this ACL relative to other ACLs that you can configure for the user role. 1 is the top.</p> <p>Default: (last)</p>
bandwidth-contract	Name of a bandwidth contract or rate limiting policy configured with the <code>aaa bandwidth-contract</code> command. The bandwidth contract must be applied to either downstream or upstream traffic.
app	<p>Name of the application bandwidth contract configured for the user role. The bandwidth contract must be applied to either downstream or upstream traffic.</p> <p>NOTE: For a complete list of supported applications, issue the command <code>show dpi application all</code>.</p>
appcategory	<p>Name of the application category bandwidth contract configured for the user role. The bandwidth contract must be applied to either downstream or upstream traffic.</p> <p>NOTE: For a complete list of supported applications, issue the command <code>show dpi application category all</code>.</p>
web-cc-category web-cc-reputation <cc-name> <bwc-name>	<p>Apply a bandwidth contract to the specified web content category or reputation level. Bandwidth contracts can be applied to user-defined web content categories created using the <code>web-cc</code> command. The five web content reputation levels are predefined in ArubaOS.</p> <p>NOTE: bandwidth contracts applied to a web content category or reputation will not be enforced</p>

Parameter	Description
	<p>unless web content classification is enabled using the <code>firewall web-content-classification</code> command.</p> <p>Range: Available reputation categories are:</p> <ul style="list-style-type: none"> ■ high-risk ■ low-risk ■ moderate-risk ■ suspicious ■ trustworthy
<code>exclude app appcategory</code>	<p>Excludes an application or application category from being configured as a bandwidth contract.</p>
<code>downstream</code>	<p>Applies the bandwidth contract to traffic from the controller to the client.</p>
<code>per-user</code>	<p>Specifies that bandwidth contract is assigned on a per-user basis instead of a per-role basis. For example, if two users are active on the network and both are part of the same role with a 500 Kbps bandwidth contract, then each user is able to use up to 500 Kbps.</p> <p>Default: (per role)</p>
<code>upstream</code>	<p>Applies the bandwidth contract to traffic from the client to the controller.</p>
<code>captive-portal <STRING></code>	<p>Name of the captive portal profile configured with the <code>aaa authentication captive-portal</code> command.</p>
<code>check-for-accounting</code>	<p>If disabled, RADIUS accounting is done for an authenticated users irrespective of the captive-portal profile in the role of an authenticated user. If enabled, accounting is not done as long as the user's role has a captive portal profile on it. Accounting will start when Auth/XML-Add/CoA changes the role of an authenticated user to a role which doesn't have captive portal profile.</p> <p>Default: Enabled</p>
<code>dialer</code>	<p>If VPN is used as an access method, name of the VPN dialer configured with the <code>vpn-dialer</code> command. The user can login using captive portal and download the dialer. The dialer is a Windows application that configures the VPN client.</p>
<code>dpi</code>	<p>Role specific DPI configuration.</p>

Parameter	Description
disable	Disable role specific DPI configuration.
ip-classification	Role specific ip-classification configuration.
disable	Disable role specific ip-classification configuration.
max-sessions	Maximum number of datapath sessions per user in this role. Range: 0-65535 Default: 65535
no	Negates any configured parameter.
openflow-enable	Enables SDN for the user role. Default: Enabled
pool	If VPN is used as an access method, specifies the IP address pool from which the user's IP address is assigned: <ul style="list-style-type: none"> ■ l2tp: When a user negotiates an L2TP or IPsec session, specifies an address pool configured with the <code>ip local pool</code> command. ■ pptp: When a user negotiates a PPTP session, specifies an address pool configured with the <code>pptp ip local pool</code> command. ■ via-dhcp: Defines an external DHCP server address instead of internal L2TP pool and the managed device gets the IP address from an external DHCP server. <p>NOTE: L2TP pool and DHCP pool configuration in a role are mutually exclusive.</p>
<name>	Name of the L2TP or PPTP or DHCP pool to be applied.
qos-profile	Applies a QOS profile to the user role.
reauthentication-interval	Interval, in minutes or seconds, after which the client is required to reauthenticate. Range: 0-4096 in minutes <ul style="list-style-type: none"> ■ 0-245760 in seconds Default: 0(disabled)
registration-role	If enabled, a user is forced to do MAC-based authentication every time the user connects to the network. Default: disabled
robust-age-out	Apply Robust Age-out mechanism on wired passive clients.

Parameter	Description
	<p>Default: Disabled.</p> <p>NOTE: This feature impacts system load and performance. Enable this mechanism for a limited number of clients only.</p>
sso	Applies an SSO profile to the user role.
stateful-kerberos	Applies a stateful Kerberos profile to the user role.
stateful-ntlm	Apply stateful NTLM authentication to the specified user role
via	Applies a VIA connection profile to the user role.
vlan	<p>Identifies the VLAN ID or VLAN name to which the user role is mapped. This parameters works only when using Layer-2 authentication such as 802.1X or MAC address, ESSID, or encryption type role mapping because these authentications occur before an IP address is assigned. If a user authenticates using a Layer-3 mechanism such as VPN or captive portal this parameter has no effect.</p> <p>NOTE: VLAN IDs and VLAN names cannot be listed together.</p>
voip-profile	Applies a VOIP profile to the user role.
web-cc disable	<p>Disable web content classification for this user role. User role bandwidth contracts associated with web content classification categories and reputation types will not enforced unless web content classification is enabled using the <code>firewall web-content-classification</code> command.</p>
wispr	Apply WISPr authentication to the specified user role.

Example

The following command configures a user role:

```
(host)[md](config) #user-role new-user
dialer default-dialer
pool pptp-pool-1
```

Command History

Release	Modification
ArubaOS 8.8.0.0	Added a new sub-parameter, <code>via-dhcp</code> , to support external DHCP server address pool instead of internal L2TP pool. Added a new parameter, <code>robust-age-out</code> , to apply a new age-out mechanism on wired passive clients.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

valid-network-oui-profile

```
valid-network-oui-profile
no
oui <oui>
```

Description

This command allows you to add a new OUI to the managed device. The new OUI must be entered in a aa:bb:cc format.

Parameter	Description
no	Negates any configured parameter.
oui <oui>	The new OUI to be added. Use the aa:bb:cc format to input the new OUI.

Example

The following example adds a new OUI to the managed device.

```
(host) [mynode] (config) #valid-network-oui-profile
(host) [mynode] (Valid Equipment OUI profile) #
(host) [mynode] (Valid Equipment OUI profile) #oui 00:11:22
This should only be used when adding equipment with a new OUI. Are you sure
you
want to proceed? [y/n]: y
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Available on all platforms	Base operating system.	Config mode on Mobility Conductor.

vlan-bwcontract-explist

```
vlan-bwcontract-explist mac <mac>
```

Description

This command adds entries to or remove entries from the MAC exception list for bandwidth contracts on broadcast or multicast traffic. Bandwidth contracts on a VLAN can limit broadcast and multicast traffic. ArubaOS includes an internal exception list to allow broadcast and multicast traffic using the VRRP, LACP, OSPF, PVST and STP protocols. To remove per-vlan bandwidth contract limits on an additional broadcast or multicast protocol, add the MAC address for that broadcast or multicast protocol to the Vlan Bandwidth Contracts MAC Exception List.

Parameter	Description
<mac>	MAC address of a protocol that should be added to or removed from the exception list for bandwidth contracts.

Example

The following example adds the MAC address for CDP and VTP to the list of protocols that are not limited by VLAN bandwidth contracts.

```
(host) [mynode] (config) #vlan-bwcontract-explist mac 01:00:0C:CC:CC:CC
```

Command History

vlan-name

```
vlan-name <name> [assignment even {ip-timeout | max-ip-timeouts | full-period} | hash]
```

Description

This command creates a named VLAN on the managed device and given an assignment type.

Parameter	Description
<name>	Name of the VLAN.
assignment	Sets the assignment type as one of the following : <ul style="list-style-type: none">▪ even: This is based on an even distribution of VLAN pool assignments.▪ hash: This is based on the station MAC address.
auto-disconnect	Enables VLAN Resiliency. Client auto disconnection on IP timeout 0-180 3
ip-timeout	Enables VLAN pooling resiliency. Configures the timeout value, in seconds, before declaring a client's DHCP request as timed out. 0-180 3
max-ip-timeouts	Configures the maximum number of IP timeouts allowed before marking the VLAN as full. 1-128 3
full-period	Time period, in seconds, for a VLAN to be marked as full. 30-3600 30

Create a named VLAN so you can set up a VLAN pool. A VLAN pool consists of a set of VLAN IDs which are grouped together to efficiently manage multi-managed device networks from a single location.

VLAN pooling should *not* be used with static IP addresses.

Perform **vlan-name** configuration changes with caution. All **vlan-name** configuration changes requires reconfiguration of all the VAPs. For large VLAN deployments it is recommended to perform **vlan-name** configuration changes during a planned maintenance window.

The Even VLAN assignment type maintains a dynamic latest usage level of each VLAN ID. Therefore, as users age out, the number of available addresses increases. This leads to a more even distribution of addresses.

The Even type is only supported in tunnel and decrypt tunnel forwarding modes. It is not supported in split or bridge modes and it is not allowed for VLAN pools that are configured directly under a virtual AP. It can only be used under named VLANs. If a VLAN is given an Even assignment in bridge mode, a message displays indicating that the Hash assignment is automatically used instead to retrieve the VLAN ID.

L2 Mobility is not compatible with the existing implementation of the Even VLAN pool assignment type.

Example

The following example creates a VLAN named **mygroup** with the assignment type “even” on the managed device:

```
(host) [mynode] (config) #vlan-name mygroup assignment even
```

Related Commands

vlan

```
vlan [<id> option-82] | [<name> <vlan-ids>] | [range remove <WORD> ] | [wired aaa-profile <profile>]
```

Description

This command creates a VLAN ID or a range of VLAN IDs on the managed device. Use the `vlan-name` command to create a named VLAN to set up a VLAN pool. A VLAN pool consists of a set of VLAN IDs which are grouped together to efficiently manage multi-managed device networks from a single location.

To enable role-based access for wired clients connected to an untrusted VLAN or port on the managed device, you must use the `wired aaa-profile` parameter to specify the wired AAA profile you would like to apply to that VLAN. If you do not specify a per-VLAN wired AAA profile, traffic from clients connected to an untrusted wired port or VLAN will use the global wired AAA profile, if configured.

Parameter	Description
<id>	Identification number for the VLAN. 2-4094 1
option-82	Turn on Option-82
<name>	(Optional) Identification name of the VLAN. The VLAN name was created using the <code>vlan-name</code> command. 1-32 characters; a name cannot begin with a numeric character VLAN<id>
<vlan-ids>	(Optional) List of VLAN IDs that are associated with this VLAN. If two or more IDs are listed, the VLAN needs to be specified first as a VLAN pool using the <code>vlan-name</code> command. Existing VLAN IDs 1
range <range>	Create a range of multiple VLAN IDs by specifying the beginning and ending VLAN ID separated by a hyphen. For example, 55-58 2-4094
remove <WORD>	List a range of vlans to be removed and it is a comma and a '-' separated list of vlans.

Parameter	Description
wired aaa-profile <profile>	Assign an AAA profile to a VLAN to enable role-based access for wired clients connected to an untrusted VLAN or port on the managed device. This parameter applies to wired clients only. Note that this profile will only take effect if the VLAN or the port on the managed device is untrusted. If both the port and the VLAN are trusted, no AAA profile is assigned.

Example

The following example creates VLAN ID 27 with the description **myvlan** on the managed device.

```
(host) [mynode] (config) #vlan 27 myvlan
```

The following example associates the VLAN IDs 5, 12 and 100 with VLAN guestvlan on the managed device.

```
vlan guestvlan 5,12,100
```

The following example creates VLAN IDs 200-300, 302, 303-400.

```
(host) [mynode] (config) #vlan range 200-300,302, 303-400
```

vpn-acl

```
vpn-acl route <vpnraclname> | session <vpnsaclname>
```

Description

This command configures both session and route ACL for branch-vpnc tunnel.

Parameter	Description
route <vpnraclname>	This parameter configures route ACL on branch-vpnc tunnel traffic
session <vpnsaclname>	This parameter configures session ACL on branch-vpnc tunnel traffic.

Example

The following example configures route ACL on branch-vpnc tunnel:

```
(host) [mynode] (config) #vpn-acl route test
```

vpn-dialer

```
vpn-dialer <name>
  enable dnetclear|l2tp|pptp|securid_newpinmode|wirednowifi
  ike {authentication {pre-share <key>|rsa-sig}|encryption {3des|des}}|
  group {1|2}|hash {md5|sha}|lifetime [<seconds>]}
  ipsec {encryption {esp-3des|esp-des}|hash {esp-md5-hmac|esp-sha-hmac}}|
  lifetime [<seconds>]|pfs {group1|group2}}
  no {enable...|ipsec...|ppp...}
  ppp authentication {cache-securid|chap|mschap|mschapv2|pap}
```

Description

This command configures the VPN dialer. A VPN dialer is a Windows application that configures a Windows client for use with the VPN services in the managed device. When VPN is used as an access method, a user can login using captive portal and download a VPN dialer. You can customize a VPN dialer for a user role configured with the `user-role` command. After the user authenticates via captive portal, a link appears to allow download of the VPN dialer if a dialer is configured for the user role.

Parameter	Description
<name>	Name that identifies this VPN dialer configuration.
enable	Enables dialer operations:
dnetclear	Enables “split tunneling” functionality so that traffic destined for the internal network is tunneled while traffic for the Internet is not. This option is not recommended for security reasons. Default: disabled
l2tp	Allows the dialer to negotiate a Layer-2 Tunneling Protocol (L2TP)/IPsec tunnel with the managed device. Default: enabled
pptp	Allows the dialer to negotiate a Point-to-Point Tunneling Protocol (PPTP) with the managed device. Default: disabled
securid_newpinmode	Supports SecurID new and next pin mode. Default: disabled
wirednowifi	Allows the dialer to detect when a wired network connection is in use, and shuts down the wireless interface. Default: disabled

Parameter	Description
ike	Configures internet key exchange (IKE) protocol. This configuration must match the IKE policy configured with the <code>crypto isakmp policy</code> command on the managed device.
authentication	Specifies whether preshared keys or RSA signatures are used for IKE authentication. Range: pre-share rsa-sig Default: pre-share
encryption	Specifies the IKE encryption protocol, either DES or 3DES. Range: 3des des Default: 3des
group	Specifies the Diffie-Hellman group, either 1 or 2. Range: 1 2 Default: 2
hash	Specifies the HASH algorithm, ether SHA or MD5. Range: md5 sha Default: sha
lifetime	Specifies how long an IKE security association lasts, in seconds. Range: 300-86400 Default: 28800 seconds
ipsec	Configures IPsec. This configuration must match the IPsec parameters configured with the <code>crypto dynamic-map</code> and <code>crypto ipsec</code> commands on the managed device.
encryption	Specifies the encryption type for IPsec, either DES or 3DES. Range: esp-3des esp-des Default: esp-3des
hash	Specifies the hash algorithm used by IPsec, either MD5 or SHA. Range: esp-md5-hmac esp-sha-hmac Default: esp-sha-hmac
lifetime	Specifies how long an IPsec security association lasts, in seconds. Range: 300-86400 Default: 7200 seconds
pfs	Specifies the IPsec Perfect Forward Secrecy (PFS) mode, either group 1 or group 2. Range: group1 group2 Default: group2

Parameter	Description
no	Negates any configured parameter.
ppp authentication	Enables the protocols for PPP authentication. This list should match the L2TP or PPTP configuration configured with the <code>vpdn</code> command on the managed device.
cache-securid	The managed device caches Secure ID tokens so that the user does not need to reauthenticate each time a network connection is lost. Default: disabled
chap	Use CHAP with PPP authentication. Default: enabled
mschap	Use MSCHAP with PPP authentication. Default: enabled
mschapv2	Use MSCHAPv2 with PPP authentication. Default: enabled
pap	Use PAP with PPP authentication. Default: enabled

Example

The following example configures a VPN dialer:

```
(host) [node] (config) #vpn-dialer default-dialer
ike authentication pre-share f00xYz123BCA
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Available on all platforms	Base operating system.	Config mode on Mobility Conductor.

vpdn group l2tp

```
vpdn group l2tp
  client configuration {dns|wins} <ipaddr1> [<ipaddr2>]
  disable|enable
  l2tp tunnel hello <seconds>
  no ...
  ppp authentication {CACHE-SECURID|CHAP|EAP|MSCHAP|MSCHAPv2|PAP}
  ppp securid cache <minutes>
```

Description

This command configures an L2TP or IPsec VPN connection. L2TP or IPsec relies on the PPP connection process to perform user authentication and protocol configuration. You must specify the protocol used for PPP authentication and whether SecureID tokens are cached on the managed device. Client addresses are assigned from a pool configured with the `ip local pool` command.

Parameter	Description
<code>client configuration</code>	Configures parameters for the remote clients.
<code>dns</code>	Configures a primary and optional secondary DNS server.
<code>wins</code>	Configures a primary and optional secondary WINS server.
<code>disable enable</code>	Disables or enables termination of L2TP clients. Default: Enabled
<code>l2tp tunnel hello</code>	Configures L2TP tunneling hello timeout, in seconds. Range: 10-1440 Default: 60 seconds
<code>no</code>	Negates any configured parameter.
<code>ppp authentication</code>	Enables the protocols for PPP authentication. This list should match the L2TP configuration configured with the <code>vpn-dialer</code> command on the managed device.
<code>CACHE-SECURID</code>	The managed device caches Secure ID tokens so that the user does not need to reauthenticate each time a network connection is lost.
<code>CHAP</code>	Use CHAP with PPP authentication.

Parameter	Description
EAP	Use EAP-TLS with PPP authentication. Specify this protocol for Windows IPsec VPN clients that use Common Access Card (CAC) Smart Cards that contain user information and digital certificates.
MSCHAP	Use MSCHAP with PPP authentication.
MSCHAPv2	Use MSCHAPv2 with PPP authentication. This is the default for L2TP
PAP	
ppp securid	If CACHE-SECURID is configured for PPP authentication, this specifies the time, in minutes, that the token is cached. Range: 15-10080 Default: 1440 minutes

Example

The following example configures virtual private dial-in networking:

```
(host) [mynode] (coinfig) #vpdn group l2tp
ppp authentication PAP
client configuration dns 10.1.1.2
client configuration wins 10.1.1.2
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

vpdn group pptp

```
vpdn group pptp
  client configuration {dns|wins} <ipaddr1> [<ipaddr2>]
  disable|enable
  no ...
  ppp authentication {MSCHAP|MSCHAPv2}
  pptp echo <seconds>
```

Description

This command configures a PPTP VPN connection. PPTP connections require user-level authentication through a PPP authentication protocol (MSHCAV2 is the currently-supported method.) Client addresses are assigned from a pool configured with the `ppp` command.

Parameter	Description
<code>client configuration</code>	Configures parameters for the remote clients.
<code>dns</code>	Configures a primary and optional secondary DNS server.
<code>wins</code>	Configures a primary and optional secondary WINS server.
<code>disable enable</code>	Disables or enables termination of PPTP clients. Default: Enabled.
<code>no</code>	Negates any configured parameter.
<code>ppp authentication</code>	Enables the protocols for PPP authentication. This list should match the PPTP configuration configured with the <code>vpdn-dialer</code> command on the managed device.
<code>MSCHAP</code>	Use MSCHAP with PPP authentication.
<code>MSCHAPv2</code>	Use MSCHAPv2 with PPP authentication. This is the default for L2TP
<code>pptp echo</code>	Time, in seconds, that the managed device waits for a PPTP echo response from the client before considering the client to be down. The client is disconnected if it does not respond within this interval. Range: 10-300 Default: 60 seconds.

Example

The following example configures virtual private dial-in networking:

```
vpdn group pptp
ppp authentication MSCHAPv2
client configuration dns 10.1.1.2
client configuration wins 10.1.1.2
```

Command History

vpnip

```
vpnip <vpncip>|v6 <vpncipv6>
  ipsec-custom-cert vpnc-mac-1-c <mac-addr> [vpnc-mac-2-c <mac-addr>] [ca-cert
  <ca>|factory-ca-cert] [fqdn <local-fqdn>] [interface vlan <id>] [server-cert
  <sc>|factory-cert] [suite-b gcm128 |gcm256]
  ipsec-factory-cert vpnc-mac-1 <mac-addr>
  peer-mac <peer-mac-1> ipsec <key> {[fqdn <local-fqdn>] [interface vlan
  <vpnvlanid>]}
```

Description

This command configures the certificate or PSK used by a managed device to create a site-to-site IPsec VPN tunnel to a controller configured as a VPN concentrator. Use this command to configure a managed device to communicate with a VPN concentrator in a deployment where both Mobility Conductor and the VPN concentrator are located within the same DMZ.

When the managed device communicates with the VPN concentrator to set up an IPsec tunnel, any uplink VLAN tag defined via the [uplink wired](#) command will be sent with the vendor-id during IKE negotiation. This setting can uniquely bind the tunnel from a particular uplink on a managed device to a corresponding crypto map on VPN concentrator.

Parameter	Description
<vpncip>	Configure the IPv4 address of the VPN concentrator.
v6 <vpncipv6>	Configure the IPv6 address of the VPN concentrator.
ipsec-custom-cert	Custom Cert-based IPsec secure communication between a VPN concentrator and a managed device.
vpnc-mac-1-c <mac-addr>	Specify the first VPN concentrator's MAC address.
vpnc-mac-2-c <mac-addr>	Specify the second VPN concentrator's MAC address.
ca-cert <ca> factory-cert	The specified CA certificate will be used to validate the certificate presented by the VPN concentrator. Enter a name of a CA certificate, or choose factory-cert to use factory-installed CA Cert chain.
fqdn <local-fqdn>	The managed device's FQDN (max 64 bytes) used in IKE. This is optional for a dynamically addressed device.
interface vlan <id>	Specify the VLAN ID of a VLAN interface that initiates the IKE tunnel. If no interface is specified, the managed device uses the switch IP.
server-cert <sc> factory-cert]	The managed device will use the specified server certificate for IPsec communication to a VPN concentrator.

Parameter	Description
<code>suite-b gcm128 gcm256</code>	Specify the GCM-128 or GCM-256 Suite B Algorithm
<code>ipsec-factory-cert</code>	Factory Cert-based IPsec secure communication between the VPN concentrator and the managed device.
<code>vpnc-mac-1-c <mac-addr></code>	Specify VPN concentrator's MAC address.
<code>peer-mac <peer-mac-1></code>	Specify Peer MAC address for PSK-based authentication.
<code>ipsec <key></code>	Enable IPsec secure communication between the VPN concentrator and the managed device using the specified key.
<code>fqdn <local-fqdn></code>	The managed device's FQDN (max 64 bytes) used in IKE. This is optional for a dynamically addressed device.
<code>interface vlan <vpnvlanid></code>	Specify the VLAN ID of a VLAN interface that initiates the IKE tunnel. If no interface is specified, the managed device uses the switch IP.

Example

The following example configures a factory certificate used by a managed device to create a site-to-site IPsec VPN tunnel to a controller configured as a VPN concentrator:

```
[host] (mynode) (config) # vpnip 192.0.0.2 ipsec-factory-cert vpn-mac-1
01:00:5E:00:00:01
```

vpn-peer peer-mac

```
vpn-peer peer-mac <mac-addr>  
  cert-auth {ca-cert <peer-ca> server-cert <peer-sc>}|factory-cert} suite-B  
  {gsm128|gsm256}  
  pre-share-key <peer-key> suite-B {gsm128|gsm256}
```

Description

This command defines IKE parameters used by a VPN concentrator to create secure tunnels between that VPN concentrator and a managed device. Use this command on controller configured as a VPN concentrator to define a VPN between that device and another managed device. When the other managed device communicates with the VPN concentrator to set up an IPsec tunnel, any uplink VLAN tag defined via the [uplink wired](#) command will be sent with the vendor-id during IKE negotiation. This setting can uniquely bind the tunnel from a particular uplink on a managed device to a corresponding crypto map on VPN concentrator.

Parameter	Description
peer-mac <mac-addr>	MAC address of the managed device. If the peer device is an x86 server, then configure the MAC address of the management interface of the managed device. However, if the peer device is a hardware platform, you must provide the MAC address of the VLAN interface of the managed device.
cert-auth	Enable certificate authentication.
ca-cert <peer-ca>	<peer-ca> is a user-defined name of a trusted CA certificate installed on the VPN concentrator. This CA certificate will be used validate the certificate presented by the managed device.
server-cert <peer-sc>	<peer-SC> is a user-defined name of a server certificate installed on the VPN concentrator. The VPN concentrator will use the specified server certificate for IPsec communication to a managed device.
factory-cert	The factory-installed CA certificate on the VPN concentrator will be used validate the certificate presented by the managed device.
suite-b {gsm128 gsm256}	Specify one of the following Suite B Algorithm: <ul style="list-style-type: none">■ gcm128: Suite B AES-GCM Algorithm parameter (128 bits)■ gcm256: Suite B AES-GCM Algorithm parameter (256 bits)
pre-share-key <peer-key>	Enable authentication using a PSK.

Parameter	Description
<code>suite-b {gsm128 gsm256}</code>	Specify one of the following Suite B Algorithm: <ul style="list-style-type: none"> ■ gcm128: Suite B AES-GCM Algorithm parameter (128 bits) ■ gcm256: Suite B AES-GCM Algorithm parameter (256 bits)

Example

The following example configures a VPN from a managed device VPN concentrator to another managed device using the factory default certificate:

```
(host)[node] (config) #vpn-peer peer-mac 01:00:5E:00:00:FF factory-cert
```

Related Commands

vpn-peer pass-code

```
vpn-peer pass-code <auth-pass-code>  
  cert-auth {ca-cert <peer-ca> server-cert <peer-sc>}|{factory-cert}
```

Description

This command automates the process of whitelisting/allowlisting the branch devices to avoid extra configuration for each device at the headend. For automatic whitelisting/allowlisting of managed devices in the VPN Concentrator, the authentication code method is used. In this method, the whitelisting/allowlisting of the device is achieved through the authentication token. You must configure the same VPN peer authentication passcode on the Mobility Conductor as well as the VPN Concentrator to whitelist/allowlist the device in the database.

Parameter	Description
pass-code <auth-pass-code>	The authenticate token to be configured on Mobility Conductor as well as the VPN Concentrator. The Mobility Conductor pushes this configuration to the managed devices for automatic whitelisting/allowlisting on the VPN Concentrator.
cert-auth	Enable certificate authentication.
ca-cert <peer-ca>	<peer-ca> is a user-defined name of a trusted CA certificate installed on the VPN concentrator. This CA certificate is used to validate the certificate presented by the managed device.
server-cert <peer-sc>	<peer-SC> is a user-defined name of a server certificate installed on the VPN concentrator. The VPN concentrator uses the specified server certificate for IPsec communication to a managed device.
factory-cert	The factory-installed CA certificate on the VPN concentrator will be used validate the certificate presented by the managed device.

Example

The following example configures an authentication code on the Mobility Conductor, which is used for automatic whitelisting/allowlisting of managed devices on a VPN concentrator where the same authenticate code is configured.

```
(host)[mynode] (config) #vpn-peer pass-code Arubal23 cert-auth factory-cert
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>whitelist</code> have been replaced with <code>allowlist</code> .
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

vrrp

```
ipv6 <id>  
  advertise <interval>  
  authentication <password>  
  description <text>  
  holdtime <secs>  
  ipv6  
  no...  
  preempt  
  priority <level>  
  shutdown  
  tracking {interface|master-up-time|vlan|vrrp-master-state}  
  vlan <vlanid>
```

Description

This command configures the VRRP. Use this command to set parameters for VRRP on the Mobility Conductor. The default VRRP parameters can be left for most implementations.

You can use a combination of numbers, letters, and characters to create the authentication password and the VRRP description. To include a space in the password or description, enter quotation marks around the string. For example, to create the password Floor 1, enter "Floor 1" at the prompt.

To change the existing password or description, enter the command with a different string. The new password or description takes affect immediately.

To unconfigure the existing password or description, enter "" at the prompt. If you update the password on one managed device, you must update the password on the redundant member pair.

Parameter	Description
id	<p>Number that uniquely identifies the VRRP instance, also known as the VRID. This number should match the VRID on the other member of the redundant pair.</p> <p>For ease in administration, you should configure this with the same value as the VLAN ID.</p> <p>After you configure the VRID, the command platform enters VRRP mode. From here, you can access the remaining VRRP commands.</p> <p>1-255</p>

Parameter	Description
ipv6	Include this optional parameter to define a VRRP using an IPv6 address.
advertise	<p>Specifies the time, in seconds, between successive VRRP advertisements sent by the current <i>master</i>. Best practices are to use the default value.</p> <p>1-60 seconds 1 second</p>
authentication	<p>Configure an optional password of up to eight characters to be used to authenticate VRRP peers in their advertisements. The password must be the same on both members of the redundant pair. The password is sent in plain-text and therefore should not be treated as a security measure. Rather, the purpose of the password is to guard against misconfigurations in the event that other VRRP devices exist on the same network. This parameter is supported only for IPv4.</p> <p>8 characters</p>
description	<p>Configure an optional text string to describe the VRRP instance.</p> <p>1-80 characters</p>
holdtime <secs>	<p>The VRRP virtual router does not begin listening to advertisements until the holdtime expires. If your deployment includes a VRRP master with preemption disabled and an uplink switch is running RSTP, a higher value will prevent the VRRP master from regaining the master state after it reboots. The holdtime is disabled by default. If enabled without mentioning a time range, the holdtime will be configured to the default value, 45 seconds.</p> <p>30-120 seconds Disabled</p>

Parameter	Description
<code>ipv6 address</code>	<p>Configure the virtual IPv6 address that will be owned by the elected VRRP <i>master</i>. Use the same IPv6 address on each member of the redundant pair.</p> <p>This IPv6 address will be redundant - it will be active on the VRRP master, and will become active on the VRRP backup in the event that the VRRP master fails.</p> <p>The IPv6 address must be unique; the IPv6 address cannot be the loopback address of the Mobility Conductor. Only IPv6 address formats are supported. Starting from ArubaOS 8.2.1.0, you can configure a unique local address as the VRRP IPv6 address on the Mobility Conductor and the managed devices.</p>
<code>no</code>	<p>Negates all configured VRRP parameters.</p>
<code>preempt</code>	<p>Preempt mode allows a managed device to take over the role of master if it detects a lower priority managed device currently acting as master.</p> <p>Best practices are to use the default value to avoid excessive interruption to users or “flapping” if a problematic managed device is cycling up and down.</p> <p>Disabled</p>
<code>delay</code>	<p>Delay value in seconds.</p> <p>Specifying a value enables the delay timer. The timer is triggered when the VRRP state moves out of backup or init state to become a master. This is applicable only if router pre-emption is enabled.</p> <p>When the timer is triggered, it delays the router for a specified period of time before taking over the master router. In the mean time, if there is an advertisement from another VRRP master (existing master), the router stops the timer and does not transition to master.</p> <p>0-60 seconds</p>

Parameter	Description
	0
<pre>priority</pre>	<p>Defines the priority level of the VRRP instance for the Mobility Conductor. This value is used in the election mechanism for the master. A higher number specifies a higher priority.</p> <p>The default priority setting is adequate for most networks.</p> <p>1-255</p> <p>100</p>
<pre>shutdown</pre>	<p>Administratively shutdown VRRP. When down, VRRP is not active, although the Mobility Conductor maintains the configuration information.</p> <p>To start the VRRP instance, use no shutdown.</p> <p>Enabled</p>
<pre>tracking</pre>	<p>Alter the virtual router priority value.</p>
<pre>interface {gigabitethernet <slot/module/port>} {sub <value>}</pre>	<p>Configures VRRP tracking based on Layer-2 interface state transitions. You can track a combined maximum of 16 VLAN and Layer-2 interfaces.</p> <ul style="list-style-type: none"> ■ <slot/module/port> - Interface in <slot>/<module>/<port> format. ■ sub - Decreases the priority of the VRRP instance by the specified number. When the interface comes up again, the value is restored to the previous priority level. The combined priority and tracking vales cannot exceed 255. If the priority value exceeds 255, the Mobility Conductor displays an error message. Valid range is 0-255.
<pre>master-up-time <duration> add <value></pre>	<p>The VLAN tracking feature monitors how long the Mobility Conductor has been master for the VRRP instance.</p> <ul style="list-style-type: none"> ■ duration - This value configures the number of

Parameter	Description
	<p>minutes that must elapse before uptime tracking takes place. Valid range is 0-1440 minutes.</p> <ul style="list-style-type: none"> ■ add - Instructs the Mobility Conductor to add the specified value to the existing priority level. The combined priority and tracking values cannot exceed 255. Valid range is 0-255. If the priority value exceeds 255, the Mobility Conductor displays an error message similar to the following - Error: Vrrp 30 priority + tracking value exceeds 255.
<pre>vlan <vlanid> {sub <value>}</pre>	<p>Configures VRRP tracking based on VLAN state transitions. The combined priority and tracking values cannot exceed 255. Valid value is 0-255. If the priority value exceeds 255, the Mobility Conductor displays an error message similar to the following - Error: Vrrp 30 priority + tracking value exceeds 255 <p>1-255</p>
<pre>vlan</pre>	<p>Specifies the VLAN ID of the VLAN on which VRRP will run.</p> <p>1-4094</p>

Interface Tracking

You can track multiple VRRP instances to prevent asymmetric routing and dynamically change the VRRP master to adapt to changes in the network. VRRP interface tracking can alter the priority of the VRRP instance based on the state of a particular VLAN or Layer-2 interface. The priority of the VRRP instance can increase or decrease based on the operational state of the specified interface. For example, interface transitions (up or down events) can trigger a recomputation of the VRRP priority, which can change the VRRP master depending on the resulting priority. You can track a combined maximum of 16 interfaces.

You must enable preempt mode to allow a managed device to take over the role of master if it detects a lower priority managed device currently acting as master

Example

The following example configures a priority of 105 for VRRP ID (VRID) 30:

```
(host) [mynode] (config) #vrrp 30
priority 105
```

The following commands configure VLAN interface tracking and assumes the following:

- You have two managed device, a primary and a backup.

- The configuration highlights the parameters for interface tracking. You may have other parameters configured for VRRP.

Primary Configuration	Backup Configuration
<pre>vrrp 10 vlan 10 ip address 10.200.22.254 priority 105 preempt tracking vlan 20 sub 10 vrrp 20 vlan 20 ip address 10.200.22.254 preempt priority 105 tracking vlan 10 sub 10 vrrp 30 vlan 30 ip address 10.200.22.254 preempt priority 105 tracking vlan 20 sub 10</pre>	<pre>vrrp 10 vlan 10 ip address 10.200.22.254 priority 100 preempt tracking vlan 20 sub 10 vrrp 20 vlan 20 ip address 10.200.22.254 preempt priority 100 tracking vlan 10 sub 10 vrrp 30 vlan 30 ip address 10.200.22.254 preempt priority 100 tracking vlan 20 sub 10</pre>

If VLAN 20 goes down, VRRP 20 automatically fails over, VRRP 10 and VRRP 30 would drop their priority to 95, causing a failover to the backup Mobility Conductor. Once VLAN 20 comes back up,

the Mobility Conductor restores the VRRP priority to 105 for all VRRP IDs and resumes the master VRRP role.

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

webcc

distributed
connectiontype ipv6

Description

This command changes the WebCC operational mode of a managed device from the default centralized mode to distributed mode. The WebCC operational mode determines whether the managed device or Mobility Conductor contacts the cloud WebRoot server for URL lookup queries. In the default centralized mode, the Mobility Conductor contacts the cloud WebRoot server for URL lookup queries, whereas in distributed mode, the managed device contacts the cloud WebRoot server for URL lookup queries.

The WebCC license allows all web traffic to be classified and allows the managed device to apply firewall policies based on web content category and reputation. The category and reputation data for each URL is obtained from an external WebRoot Server. The WebCC feature can operate in two distinct modes, which control whether the managed device or Mobility Conductor performs the WebCC content lookup tasks. This command can be executed only from the **/md** subtree of the Mobility Conductor.

Parameter	Description
distributed	Sets the WebCC mode for the managed device to distributed mode.
connectiontype ipv6	Sets the WebCC connection type from IPv4 to IPv6 address. The default is IPv4.

Centralized Mode

In the default **centralized** mode, only Mobility Conductor downloads the URL entry database from the WebRoot Server. If a URL for web traffic sent through the managed device does not appear in its datapath cache, the managed device sends a query request to Mobility Conductor. The Mobility Conductor queries the WebRoot Server, adds the response to its database and sends information about the URL back to the managed device.

WebCC license usage is calculated for each license pool, and the total count in each pool is sent to each managed device within that pool. If the WebCC licenses expire, or the available WebCC licenses are fewer than the AP licenses, then individual managed devices within that pool will no longer be able to send query requests to Mobility Conductor, and WebCC classification will be blocked.

If WebCC classification is blocked due to expired or insufficient licenses, individual managed devices continue to classify requested URLs currently available in the managed device datapath cache until the cache entries time out (usually over a period of 24 to 96 hours, depending upon the reputation level of the URL).

Distributed Mode

In **distributed** mode, each individual managed device downloads the complete URL entry database (approximately 22 MB) directly from the WebRoot Server. If a URL for web traffic sent through the managed device does not appear in this database, the managed device sends a query to the WebRoot Server, then adds the response to its datapath cache.

WebCC license usage is calculated for each license pool, and the total count in each pool is sent to each managed device within that pool. If the WebCC licenses expire, or the available WebCC licenses are fewer than the AP licenses, then individual managed devices within that pool will no longer be able to send new query requests to the WebRoot server. However, the WebCC feature continue to classify requested URLs that are already in the URL entry database on the managed device.

Example

The following example changes the WebCC operational mode of a managed device from the default centralized mode to distributed mode.

```
(host) [md] (config) #webcc distributed
```

Command History

Release	Modification
ArubaOS 8.4.0.0	The <code>connectiontype ipv6</code> parameter was added.
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	WebCC license.	Config mode on Mobility Conductor.

web-cc global-bandwidth-contract

```
web-cc global-bandwidth-contract
  web-cc-category <category-name> downstream|upstream kbits|mbits <bandwidth>
  web-cc-reputation high-risk|low-risk|moderate-risk|suspicious|trustworthy
  downstream|upstream kbits|mbits <1-2000>
```

Description

This command defines global bandwidth contracts for HTTP or HTTPS traffic matching a predefined web content category or reputation type.

The web content classification feature classifies all (HTTP/HTTPS) web traffic on the network. ArubaOS uses the Webroot® classification categories and risk reputation levels, URL database and URL cloud look-up service to classify the web traffic. You can create firewall policies and bandwidth contracts based upon these web traffic classification and reputation types.

Parameter	Description
web-cc-category <category-name>	Specify a web content category to apply a bandwidth contract to that category type. To see the full list of available web content categories, issue the command <code>show web-cc categories</code> .
downstream upstream	Specify downstream to apply the bandwidth contract to downstream traffic from the Mobility Conductor. Specify upstream to apply the contract to upstream traffic to the Mobility Conductor.
kbits mbits	Select kbits to define the contract bandwidth in kilobits/second. Select mbits to define the contract in megabits/second.
bandwidth	Define the contract value, If you are defining the bandwidth value in kilobits/second, the supported range is 256-2,000,000 kbits. If you are defining the bandwidth value in megabits/second, the supported range is 1-2000 mbits. 256-2,000,000 kbits 1-2000 mbits
web-cc-reputation high-risk low-risk moderate-risk suspicious trustworthy	Define a bandwidth contract for traffic associated with one of five predefined reputation types. Session ACLs can be applied to these risk categories using the <code>ip access-list session</code> command.

Example

The following example creates a 100 megabit/second bandwidth contract for a category called **music**:

```
(host) [/md] (config) #web-cc global-bandwidth-contract web-cc-category
music downstream mbits 100
```

web-proxy server

```
web-proxy server <name>  
    port
```

Description

This command configures the web-proxy server related information.

When the Mobility Conductor needs to access data on the cloud or the internet, and if the internet bound traffic needs to pass through a proxy, execute the `web-proxy server` command. Once the command is executed the Mobility Conductor routes web (HTTP/HTTPS) traffic through the proxy server.

Parameter	Description
<name>	Specifies the proxy server name / IP address.
port	Specifies the proxy server port.

Example

The following example configures the web-proxy server related information:

```
(host) [mynode] (config) #web-proxy server arubaproxy.com port 8080
```

web-server profile

```
web-server profile
  absolute-session-timeout <30-3600>
  bypass-cp-landing-page
  captive-portal-cert <name>
  ciphers {high|low|medium}
  cipher-suite <cipher(s)>
  exclude-http-security-headers
  idp-cert <idp-cert>
  mgmt-auth [certificate] [username/password]
  no ...
  session-timeout <session-timeout>
  ssl-protocol [tlsv1 | tlsv1.1 | tlsv1.2]
  switch-cert <name>
  via-client-cert-port <via-client-cert-port>
  web-https-port-443
  web-max-clients <web-max-clients>
```

Description

This command configures the Mobility Conductor's web server.

There is a default server certificate installed in the Mobility Conductor, However this certificate does not guarantee security in production networks. Best practices are to replace the default certificate with a custom certificate issued for your site by a trusted CA. See the *ArubaOS User Guide* for more information about how to generate a CSR to submit to a CA and how to import the signed certificate received from the CA into the Mobility Conductor. After importing the signed certificate into the Mobility Conductor, use the `web-server profile` command to specify the certificate for captive portal or WebUI access. If you need to specify a different certificate for captive portal or WebUI access, use the `no` command to revert back to the default certificate before you specify the new certificate (see the Example section).

You can use client certificates to authenticate management users. If you specify certificate authentication, you need to configure certificate authentication for the management user with the `mgmt-user webui-cacert` command.

Parameter	Description
<code>absolute-session-timeout</code> <code><30-3600></code>	Specifies the absolute time after which the WebUI session times out post a successful authentication. 30-3600 seconds 0 (disabled)

Parameter	Description
bypass-cp-landing-page	<p>If disabled, the Mobility Conductor uses the new redirection scheme also known as the landing page by default including the meta tag. This can reduce the CPU load on the Mobility Conductor. The Mobility Conductor falls back to the old redirection scheme if this parameter is enabled.</p> <p>disabled</p>
captive-portal-cert	<p>Specifies the name of the server certificate associated with captive portal. Use the <code>show crypto-local pki ServerCert</code> command to see the server certificates installed in the Mobility Conductor.</p> <p>default</p>
ciphers	<p>Configures the strength of the cipher suite: high: encryption keys larger than 128 bits low: 56 or 64 bit encryption keys medium: 128 bit encryption keys This command is not available in FIPS software images because ciphers are pre-configured only to acceptable values. high, low, medium Default: high This parameter is available only for ArubaOS 8.10.0.0 and versions prior to that.</p>
cipher-suite <cipher(s)>	<p>Enables cipher suites. Default: GCM encryption based cipher suites. Starting from 8.11.0.0, specific cipher suites can be enabled from the list of supported ciphers suites.</p>
exclude-http-security-headers	<p>Excludes security headers from HTTP response.</p>
idp-cert	<p>Specifies the IDP certificate name configured in the Mobility Conductor.</p>
mgmt-auth	<p>Specifies the authentication method for the management user; you can choose to use either username or password or certificates, or both username or password and certificates. username/password, certificate username/password</p>
no	<p>Negates any configured parameter.</p>

Parameter	Description
<pre>session-timeout <session-timeout></pre>	<p>Specifies the time of inactivity after which the WebUI session times out and requires login for continued access.</p> <p>30-3600 seconds 900 seconds</p>
<pre>ssl-protocol</pre>	<p>Specifies the SSL or TLS protocol version used for securing communication with the web server:</p> <ul style="list-style-type: none"> ■ TLS v1 ■ TLS v1.1 ■ TLS v1.2 <p>Default: tlsv1.2</p>
<pre>switch-cert</pre>	<p>Specifies the name of the server certificate associated with WebUI access. Use the <code>show crypto-local pki ServerCert</code> command to see the server certificates installed in the Mobility Conductor.</p> <p>default</p>
<pre>via-client-cert-port <via-client-cert-port></pre>	<p>Configures a port for VIA client certificate-based authentication.</p>
<pre>web-https-port-443</pre>	<p>Enables WebUI access on the HTTPS port (443). When you connect to the WebUI using https (tcp port 443), the Mobility Conductor continues using port 443 and no longer redirects to port 4343.</p>
<pre>web-max-clients <web-max-client></pre>	<p>Configures the web server's maximum number of supported concurrent clients.</p> <p>25-320 75</p>

Example

The following example configures the Mobility Conductor's web server:

```
(host) [/md] (config) #web-server profile
absolute-session-time.. Configure user's absolute WebUI session timeout
<30-3600> (seconds)
bypass-cp-landing-page Enable bypass captive portal landing page
captive-portal-cert Server Certificate for Captive Portal
cipher-suite<cipher(s)> Enable cipher suites. GCM encryption based cipher
suites are default
exclude-http-security.. Exclude security headers from HTTP response
```

```

idp-cert                Server Certificate for IDP
mgmt-auth               Configure management user's WebUI access method,
either
username/password authentication or certificate
authentication or both. Default is username/password
authentication
no                       Delete Command
session-timeout         Configure user's WebUI session timeout <30-3600>
(seconds)
ssl-protocol            Configure SSL/TLS protocol. Default is TLSv1.2.
switch-cert            Server Certificate for Management WebUI
via-client-cert-port    Port number used for VIA client-cert based profile
download. Valid range is <1025-65535>. Default value is
8085
web-https-port-443     Enable WebUI access on HTTPS port (443)
web-max-clients         Configure web servers' maximum supported concurrent
clients <25-320>

```

The following example configures WebUI access with client certificates only, and specify the server certificate for the Mobility Conductor:

```

(host) [/md] (config) #web-server profile
(host) [/md] (Web Server Configuration) #mgmt-auth certificate
(host) [/md] (Web Server Configuration) #switch-cert ServerCert1
(host) (Web Server Configuration) #!
(host) [/md] (config) #mgmt-user webui-cacert test_string serial 1111 admin
root

```

To specify a different server certificate, use the `no` command to revert back to the default certificate *before* you specify the new certificate:

```

(host) [/md] (config) #web-server profile
(host) [/md] (Web Server Configuration) #mgmt-auth certificate
(host) [/md] (Web Server Configuration) #switch-cert ServerCert1
(host) [/md] (Web Server Configuration) #no switch-cert
(host) [/md] (Web Server Configuration) #switch-cert ServerCert2

```

Command History

Release	Modification
ArubaOS 8.11.0.0	The cipher-suite <cipher(s)> parameter was introduced. The ciphers parameter was removed.
ArubaOS 8.7.0.0	TLS v1.2 is the default ssl-protocol in the Web-Server. TLS v1 and TLS v1.1 is disabled by default.
ArubaOS 8.0.0.0	Command introduced.

websocket clearpass

```
websocket clearpass
  enable
  no
  primary host <host> port <1-65535> username <username> passwd <passwd>
  secondary host <host> port <1-65535> username <username> passwd <passwd>
```

Description

This command configures the ClearPass WebSocket profile. This command configures the primary and secondary ClearPass Insight server.

Parameter	Description
enable	Enable ClearPass WebSocket interface.
no	Remove or negate a parameter.
primary	Configure the primary ClearPass Insight server. This parameter has the following sub-parameters: <ul style="list-style-type: none">■ host-The primary ClearPass Insight server IP address.■ port-The port number of the ClearPass Insight server.■ username- The name of the user who can perform the action on the server.■ passwd- The password of the user. port: 1-65535 username: 1-255 bytes password: 6-100 bytes port: 443
secondary	Configure the secondary ClearPass Insight server. This parameter has the following sub-parameters: <ul style="list-style-type: none">■ host-The primary ClearPass Insight server IP address.■ port-The port number of the ClearPass Insight server.■ username- The name of the user who can perform the action on the server.■ passwd- The password of the user. port: 1-65535 username: 1-255 bytes password: 6-100 bytes port: 443

Example

The following example configures the ClearPass WebSocket interface and the primary and secondary ClearPass Insight server:

```
(host) [mynode] (config) #websocket clearpass
(host) [mynode] (ClearPass WebSocket Profile) #primary host
security67.acmecompany.com port 443 username admin passwd changeme
(host) [mynode] (ClearPass WebSocket Profile) #secondary host 10.17.5.210
port 443 username aosadmin passwd changeme
(host) [mynode] (ClearPass WebSocket Profile) #enable
(host) [mynode] (ClearPass WebSocket Profile) #write memory

wipe

wipe out flash

Description

This command erases all data including configuration, logs, license keys, flash backup files and formats the flash file system in the controller. This command can also be used to return the Mobility Conductor or the managed devices to the factory default state. After issuing the command and rebooting the controller, you can return the controller to an operational state by installing the ArubaOS image again.

Issue this command only when the controller is taken out of service or decommissioned.

Example

The following example formats the flash file system:

```
(host) #wipe out flash
Do you really want to wipe out the entire flash (y/n): y
Zeroing out flash:.....
Flash zeroed out successfully.
```

wlan 6ghz-rrm-ie-profile

```
wlan 6ghz-rrm-ie-profile <profile-name>
  bss-aac-ie-6ghz
  clone
  country-ie-6ghz
  enabled-capabilities-ie-6ghz
```

```
no
pwr-constraint-ie-6ghz
qbss-load-ie-6ghz
quiet-ie-6ghz
tpc-report-ie-6ghz
```

Description

This command configures a Radio Resource Management (RRM) Information Elements (IE) profile to define the information elements advertised by a Wi-Fi 6E AP for 6 GHz band. ArubaOS supports RRM IEs for Wi-Fi 6E APs with 802.11ax support enabled. All IEs are sent by default.

Parameter	Description
bss-aac-ie-6ghz	The AP advertises the BSS Available Admission Capacity IE in beacon and probe responses for 6 GHz band. The BSS Available Admission Capacity IE contains information about the admission capabilities for each User Priority or AC.
clone	Copy the settings of an existing RRM IE profile for 6 GHz band.
country-ie-6ghz	The AP advertises the device's regulatory domain in beacon and probe responses.
enabled-capabilities-ie-6ghz	The AP advertises support for radio measurements in a device in beacon and probe responses for 6 GHz band.
no ...	Disables the transmission of an IE in this profile.
pwr-constraint-ie-6ghz	The AP advertises the regulatory maximum transmit power for that current channel in beacon and probe responses for 6 GHz band.
qbss-load-ie-6ghz	The AP advertises the QBSS Load IE in beacon and probe responses for 6 GHz band. The QBSS Load IE contains information on the current station count, channel utilization, and available admission capacity levels in the QBSS.
quiet-ie-6ghz	The AP advertises the Quiet IE in beacon and probe responses for 6 GHz band. Quiet IE is used to silence the channel for measurement purposes. When an AP uses a Quiet IE to schedule a quiet interval, stations may not transmit on that channel during the quiet interval.
tpc-report-ie-6ghz	The AP advertises information about its TCP in beacon and probe responses for 6 GHz band.

Example

The following example allows the Wi-Fi 6E AP to advertise the country IE.

```
(host) [md] (config) #wlan 6ghz-rrm-ie-profile default
(host) [md] (RRM IE Profile for 6 GHz "default") #country-ie-6ghz
```

wlan anyspot-profile

```
wlan anyspot-profile <profile-name>
  clone <profile-name>
  enable-anyspot
  exclude-ssid <exclude-ssid>
  exclude-wildcard <exclude-wildcard>
  no
  preset-ssid <preset-ssid>
```

Description

The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.

When an AP is configured to use this feature, the anyspot AP radio hides its configured ESSID in beacons, and compiles a list of other ESSIDs from detected neighboring APs. If the client sends a probe request without a specified ESSID, the anyspot AP will respond with a preconfigured ESSID.

When a client searches for a preferred network, that client sends the SSID of the preferred network in the probe request. The anyspot AP checks to see if there is a neighboring AP using that ESSID that can respond the client's request. If no matching network is found, the anyspot AP sends a response to the client using the SSID from the client request. If the client is authorized to connect to the anyspot AP, that client associates to AP. Once connected to the anyspot AP, the client recognizes the ESSID to which it is connected as one associated with its preferred network, and does not send out any further probe requests.

Parameter	Description
<code>clone <profile-name></code>	Make a copy of an existing anyspot profile.
<code>enable-anyspot</code>	Issue this command to enable the anyspot feature. Note that you must associate the anyspot profile with a virtual AP profile for the settings to take effect.
<code>exclude-ssid <exclude-ssid></code>	An anyspot-enabled radio will not respond to client probe requests using an ESSID in the Exclude ESSID lists. To add an ESSID to the list, enter the full name of the ESSID, then click Add . To remove an ESSID from the list, select it and click Delete . ESSIDs from neighboring APs will automatically appear in this list as long as the anyspot-enabled AP can detect that ESSID.
<code>exclude-wildcard <exclude-wildcard></code>	An anyspot-enabled radio will not respond to client probe requests using an ESSID in the Exclude ESSID list. To exclude ESSIDs that partially match a text string, enter that string then click Add . To remove a matching string from the list, select it and click Delete .

Parameter	Description
no	Remove or negate any configured parameter.
preset-ssid <preset-ssid>	The anyspot-enabled AP will not send an ESSID in beacons, but if a client sends a probe request without an ESSIDs (that is, the probe request is not looking for a specific network) then the anyspot-enabled AP will respond to the probe request with an ESSID from this list.

Example

The following example defines a ESSID to be returned in probe requests that do not contain an ESSID, as well as two ESSIDs that should be excluded from anyspot responses, in the event that a client is probing for one of these excluded ESSIDs.

```
(host) [/md] (config) #wlan anyspot-profile anyspot1
(host) [/md] (Anyspot profile "anyspot1") #preset SSID companyguest
(host) [/md] (Anyspot profile "anyspot1") #exclude-ssid corp_dev_essid
(host) [/md] (Anyspot profile "anyspot1") #exclude-ssid corp_voip_essid
```

Description

Configures a Beacon Report Request Profile to provide the parameters for the Beacon Report Request frames. The Beacon Report Request profile is configured under the 802.11K profile.

Parameter	Description
<profile-name>	Name of this instance of the profile. The name must be 1-63 characters. "default
bssid <bssid>	BSSID included in the beacon request. wildcard
channel <channel>	This option is used to set the Channel field in the Beacon Report Request frame. The Channel value can be set to one of the following: <ul style="list-style-type: none">■ The channel of the AP (when Measurement Mode is set to either 'Passive' or 'Active-All channels')■ 0 (when Measurement Mode is set to 'Beacon Table')■ 255 (when Measurement Mode is set to 'Active-Channel Report') For 802.11b/g band: 1 to 14 For 802.11a band: 36 to 165 255

Parameter	Description
clone <source>	Creates a copy of the Beacon Report Request Profile specified as the <source>. <source> is the name of an existing Beacon Report Request Profile from which parameter values are copied.
include-ssid	Include SSID IE in Beacon Report Request. Enable
interface <interface>	This field is used to specify the radio interface for transmitting the Beacon Report Request frame. 0-1 1
last-beacon-rpt-indication	Enable Last Beacon Request Indication sub-element in Beacon Report Request. Disable
measure-dur-mandatory	This value is used to set the Duration Mandatory bit of the Measurement Request Mode field of the Beacon Report Request frame. Disabled
measure-duration <measure-duration>	This value is used to set the Measurement Duration field in the Beacon Report Request frame. The Measurement Duration is set to the duration of the requested measurement. It is expressed in units of TUs. 0 – 65535 0
measure-mode	Indicates the mode used for the measurement. The valid measurement modes are: <ul style="list-style-type: none"> ■ active-all-ch—Enables active beacon measurement mode. In this mode, the client sends a probe request to the broadcast destination address on all supported channels, sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report. ■ active-ch-rpt—In this mode, the client and returns a report that contains a list of channels in a regulatory class where a client is likely to find an AP, including the AP transmitting the AP channel report. ■ beacon-table—Enables beacon-table beacon measurement mode. In this mode, the client measures beacons and returns a report with stored beacon information for any supported channel with the requested SSID and BSSID. The client does not perform any additional measurements. ■ passive—Enables passive beacon measurement

Parameter	Description
	<p>mode. In this mode, the client sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.</p> <p>NOTE: If a station doesn't support the selected measurement mode, it returns a Beacon Measurement Report with the Incapable bit set in the Measurement Report Mode field. Default Mode: beacon-table</p> <p>beacon-table</p>
no	Negates any configured parameter.
<pre>random-interval <random-interval></pre>	<p>This value is used to set the Randomization Interval field in the Beacon Report Request frame. The Randomization Interval is used to specify the desired maximum random delay in the measurement start time. It is expressed in units of TUs (Time Units). A Randomization Interval of 0 in a measurement request indicates that no random delay is to be used.</p> <p>0 – 65535</p> <p>0</p>
<pre>reg-class {auto 1 12 81 115 131}</pre>	<p>This option is used to specify the Regulatory Class field in the Beacon Report Request frame.</p> <p>Range: auto, 1, 12, 81, 115, 131</p> <p>Default: auto</p> <p>For 802.11b/g bands, use 12.</p> <p>For 802.11a band, use 1</p> <p>Auto uses value based on country code.</p>
<pre>request-info <request-info></pre>	<p>This option is used to indicate the contents of the Request Information IE that could be present in the Beacon Report Request frame. The Request Information IE is present for all Measurement Modes except the Beacon Table mode. It consists of a list of Element IDs that should be included by the client in the response frame.</p> <p>Any valid element ID in the x/y/z format. For example, 0/21/22.</p>
<pre>rpt-condition <rpt-condition></pre>	<p>This option is used to indicate the value for the Reporting Condition field in the Beacon Reporting Information sub-element present in the Beacon Report Request frame.</p> <p>0 - 255</p> <p>0</p>

Parameter	Description
rpt-detail	This option is used to indicate the value for the Detail field in the Reporting Detail sub-element present in the Beacon Report Request frame. Disabled
ssid <ssid>	A unique character string (sometimes referred to as a network name), consisting of no more than 32 characters. The SSID is case-sensitive (for example, WLAN- 01).

Example

The following example configures the parameters under **bcn-rpt-req-profile**.

```
(host) [/md] (config) #wlan bcn-rpt-req-profile default
(host) [/md] (Beacon Report Request Profile "default") #channel 9
(host) [/md] (Beacon Report Request Profile "default") #interface 1
(host) [/md] (Beacon Report Request Profile "default") #no measure-dur-
mandatory
(host) [/md] (Beacon Report Request Profile "default") #measure-duration
100
(host) [/md] (Beacon Report Request Profile "default") #measure-mode
active-all-ch
(host) [/md] (Beacon Report Request Profile "default") #random-interval 100
(host) [/md] (Beacon Report Request Profile "default") #reg-class 12
(host) [/md] (Beacon Report Request Profile "default") #rpt-condition 2
(host) [/md] (Beacon Report Request Profile "default") #no rpt-detail
(host) [/md] (Beacon Report Request Profile "default") #request-info
0/21/22
(host) [/md] (Beacon Report Request Profile "default") #ssid aruba-ap
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The values auto , 81 , 115 , and 131 were introduced for the <code>reg-class</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

range-connect
ssid-profile
```

Description

You can push WLAN profiles to users computers that use the Microsoft Windows Wireless Zero Config (WZC) service to configure and maintain their wireless networks. After the WLAN profiles are pushed to user computers, they are automatically displayed as an ordered list in the preferred networks.

Parameter	Description
auth-as-computer	Authenticate with domain credentials.
auth-as-guest	Authenticate as a guest user.
clone	Copy settings from another WLAN client profile.
eap-cert	If you select EAP type as certificate, you can use one of the following options: <ul style="list-style-type: none">■ use-smartcard■ simple-certificate-selection■ use-different-name■ validate-server-certificate
eap-cert-connect-only-to	Comma separated list of servers.
eap-peap	Configure one of the following EAP-PEAP settings: <ul style="list-style-type: none">■ disconnect-if-no-crypto■ dont-allow-user-authorize■ enable-fast-reconnect■ enable-quarantine-checks

Parameter	Description
	<ul style="list-style-type: none"> ■ validate-server-certificate
eap-peap-connect-only-to	Comma separated list of servers.
eap-type	<p>Select one of the following EAP types used by the client to connect to wireless network:</p> <ul style="list-style-type: none"> ■ eap-peap - Select this option to specify EAP-PEAP as the authentication protocol. ■ eap-tls - Select this option to specify EAP-TLS as the authentication protocol. <p>EAP-PEAP</p>
enable-8021x	<p>Select this option to enable 802.1X authentication for this network.</p> <p>Enabled</p>
ieap-cert-connect-only-to	Command separated list of servers that the Inner EAP Certificates connects to.
inner-eap	<p>Enter the inner EAP type.</p> <p>EAP-MSCHAPv2</p>
inner-eap-type	<p>Specify one of the following:</p> <ul style="list-style-type: none"> ■ eap-gtc - Select this option to specify EAP-GenericTokenCard as the inner authentication protocol. ■ eap-mschapv2 - Select his option to specify EAP-MSCHAPV2 as the inner authentication protocol.
no	Negate and reset all configuration settings.
non-broadcasting-connection	<p>Connect even if WLAN is not broadcasting.</p> <p>Disabled</p>
range-connect	Automatically connect to this WLAN if in range.
ssid-profile	Enter the name of the SSID profile.

```

Description

This command configures a 802.11k radio profile. In a 802.11k network, if the AP with the strongest signal is reaches its maximum capacity, clients may connect to an under utilized AP with a weaker signal. A 802.11k profile can assigned to each virtual AP.

Parameter	Description
<profile-name>	Name of this instance of the profile. 1-63 characters default
ap-chan-rpt-11a <ap-chan-rpt-11a>	This value is sent in the Channel field of the AP channel reports on the 'A' radio. 34-165 36
ap-chan-rpt-11bg <ap-chan-rpt-11bg>	This value is sent in the Channel field of the AP channel reports on the 'BG' radio. 1-14 1
ap-chan-rpt-6ghz <ap-chan-rpt-6ghz>	This value is sent in the Channel field of the AP channel reports on the 6 GHz radio. 1-233 1

Parameter	Description
bcn-measurement-mode	<p>Configures a beacon measurement mode for the profile.</p> <ul style="list-style-type: none"> ■ active-all-ch—Enables active beacon measurement mode. In this mode, the client sends a probe request to the broadcast destination address on all supported channels, sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report. ■ active-ch-rpt—In this mode, the client and returns a report that contains a list of channels in a regulatory class where a client is likely to find an AP, including the AP transmitting the AP channel report. ■ beacon-table—Enables beacon-table beacon measurement mode. In this mode, the client measures beacons and returns a report with stored beacon information for any supported channel with the requested SSID and BSSID. The client does not perform any additional measurements. ■ passive—Enables passive beacon measurement mode. In this mode, the client sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report. <p>NOTE: If a station doesn't support the selected measurement mode, it returns a Beacon Measurement Report with the Incapable bit set in the Measurement Report Mode field. Default Mode: beacon-table</p> <p>beacon-table</p>
beacon-table	<p>Enables beacon-table beacon measurement mode. In this mode, the client measures beacons and returns a report with stored beacon information for any supported channel with the requested SSID and BSSID. The client does not perform any additional measurements. This is the default beacon measurement mode.</p> <p>NOTE: If a station doesn't support beacon-table measurement mode, it returns a Beacon Measurement Report with the <i>Incapable</i> bit set in the <i>Measurement Report Mode</i> field.</p>

Parameter	Description
passive	<p>Enables passive beacon measurement mode. In this mode, the client sets a measurement duration timer, and, at the end of the measurement duration, compiles all received beacons or probe response with the requested SSID and BSSID into a measurement report.</p> <p>NOTE: If a station doesn't support passive measurement mode, it returns a Beacon Measurement Report with the <i>Incapable</i> bit set in the <i>Measurement Report Mode</i> field.</p>
clone <profile-name>	Copy settings from another specified 802.11k profile.
bcn-req-chan-11a <bcn-req-chan-11a>	<p>This value is sent in the Channel field of the beacon requests on the 'A' radio.</p> <p>34 to 165</p>
bcn-req-chan-11bg <bcn-req-chan-11bg>	<p>This value is sent in the Channel field of the Beacon Requests on the BG radio.</p> <p>1 to 14 or 0 to 255</p>
bcn-req-time <bcn-req-time>	<p>This option configures the time duration between two consecutive beacon requests sent to a802.11k client. By default, the beacon requests are sent to a802.11k client every 60 seconds. However, if a different value is required, the <code>bcn-req-time</code> option can be used.</p> <p>10-200 seconds 60 seconds</p>
bcn-rpt-req-profile <profile-name>	Beacon Report Request Settings for the selected profile.
dot11k-enable	<p>Enables the 802.11K feature. This feature is disabled by default.</p> <p>Disabled</p>
force-dissasoc	<p>This feature allows the AP to forcefully disassociate on-hook voice clients (clients that are not on a call) after period of inactivity. Without the forced disassociation feature, if an AP has reached its CAC limits and an on-hook voice client wants to start a new call, that client may be denied. If forced disassociation is enabled, those clients can associate to a neighboring AP that can fulfill their QoS requirements.</p>

Parameter	Description
	<p>NOTE: This feature is disabled by default.</p> <p>Disabled</p>
<code>lm-req-time <lm-req-time></code>	<p>This option configures the time duration between two consecutive link measurement requests sent to an 802.11k client. By default, link measurement requests are sent to a 802.11k client every 61 seconds. However, you can use the <code>lm-req-time</code> option to specify different time interval.</p> <p>10 to 200 seconds 60 seconds</p>
<code>nb-resp-wide-band-ie</code>	<p>Includes the wide channel bandwidth information element in the neighbor report responses, when the dot11k setting is enabled on the managed device.</p>
<code>no</code>	<p>Negates or removes any configured parameter.</p>
<code>rrm-ie-profile <profile-name></code>	<p>RRM IE Settings Profile.</p>
<code>tsm-req-profile <profile-name></code>	<p>TSM Report Request Settings Profile.</p>
<code>tsm-req-time <tsm-req-time></code>	<p>This option configures the time duration between two consecutive transmit stream measurement requests sent to a 802.11k client. By default, the transmit stream measurement requests are sent to a 802.11k client every 90 seconds. However, you can use the <code>tsm-req-time</code> option to specify a different time interval.</p> <p>10 seconds to 200 seconds. 90 seconds</p>

Example

The following example enables the 802.11k feature on the 802.11k profile and configures the beacon measurement mode and specifies the time interval for beacon, link, and transmit stream measurement requests.

```
(host) [/md] (config) #wlan dot11k-profile default
(host) [/md] (802.11K Profile "default") #dot11k-enable
(host) [/md] (802.11K Profile "default") #bcn-measurement-mode beacon-table
(host) [/md] (802.11K Profile "default") #bcn-req-time 60
```

```
(host) [/md] (802.11K Profile "default") #lm-req-time 60
(host) [/md] (802.11K Profile "default") #tsm-req-time 90
```

Related Command

wlan dot11r-profile

```
wlan dot11r-profile <profile-name>  
  clone  
  dot11r  
  key-duration <60-86400>  
  key-assignment  
  mob-domain-id <1-65535>  
  no
```

Description

This command configures an 802.11r radio profile. You can enable and configure Fast BSS Transition on a per Virtual AP basis. You must create an 802.11r profile and associate that with the Virtual AP profile through an SSID profile.

Parameter	Description
<profile-name>	Name of this instance of the profile. 1-63 characters Default
clone	Name of an existing dot11r-profile from which the parameter values are copied.
mob-domain-id	An ID that uniquely identifies the mobility domain. 1-65535 1
dot11r	Enables the Fast BSS Transition capability. Disabled
no	Negates or removes any configured parameter.
key-duration	The r1 key timeout value in seconds for decrypt-tunnel or bridge mode. 60-86400 3600
key-assignment	The list of neighbor APs for decrypt-tunnel or bridge mode. <ul style="list-style-type: none">■ static: Get neighbor AP list from ARM or VBR.■ dynamic: Use all APs from ap-group as the neighbor list.

Example

The following examples enable the 802.11r capability on the 802.11r profile, configures the Fast BSS mobility domain ID, and specifies the r1 key time-out value.

```
(host) [/md] (config)#wlan dot11r-profile default
(host) [/md] (802.11r Profile "default") #fastbss-transition
(host) [/md] (802.11r Profile "default") #fastbss-mob-domain-id 25
(host) [/md] (802.11r Profile "default") #r1key_validity_duration 2500
```

Configure a mobility domain ID that uniquely identifies a mobility domain using the following command:

```
(host) [mynode] (802.11r Profile "default") #mob-domain-id <1-65535>
```

The default value is 1.

Configure the r1 key timeout value in seconds for decrypt-tunnel or bridge mode using the following command:

```
(host) [mynode] (802.11r Profile "default") #key_duration <60-86400>
```

The default value is 3600 seconds.

Apply the 802.11r profile to an SSID profile using the following command:

```
(host) [mynode] (config) #wlan ssid-profile voice dot11r-profile voice-enterprise
```

You can advertise the 802.11r capability on the Virtual AP profile by applying the SSID profile. Use the following command to apply the SSID profile to the Virtual AP profile:

```
(host) [mynode] (config) #wlan virtual-ap voice-AP ssid-profile voice
```

Description

This command configures an EDCA profile for APs or for clients (stations).

EDCA profiles are specific either to APs or clients. You apply an EDCA profile to a specific SSID profile. Use this command only under the guidance of your Aruba technical support representative.

Parameter	Description
<profile-name>	Name of this instance of the profile. 1-63 default
background	Configures the background queue.
best-effort	Configures the best-effort queue.
clone	Name of an existing EDCA profile from which parameter values are copied.
no	Remove or negate a parameter.
video	Configures the video queue.
voice	Configures the voice queue.
acm	Specifies mandatory admission control. The client reserves the AC through TSPEC signaling. 0-disable, 1-enable 0
aifsn	Arbitrary inter-frame space number.

Parameter	Description
	0-15 0
ecw-max	The exponential (n) value of the maximum contention window size, as expressed by 2^n-1 . A value of 4 computes to $2^4-1 = 15$. 0-15 0
ecw-min	The exponential (n) value of the minimum contention window size, as expressed by 2^n-1 . A value of 4 computes to $2^4-1 = 15$. 0-15 0
txop	TXOP in units of 32 microseconds. Divide the desired transmission duration by 32 to determine the value to configure. For example, for a transmission duration of 3008 microseconds, enter 94 (3008/32). 0-2047 0

The following are the default values configured for APs:

Access Category	ecw-min	ecw-max	aifsn	txop	acm
best-effort	4	6	3	0	No
background	4	10	7	0	No
video	3	4	1	94	No
voice	2	3	1	47	No

The following are the default values configured for clients:

Access Category	ecw-min	ecw-max	aifsn	txop	acm
best-effort	4	10	3	0	No
background	4	10	7	0	No
video	3	4	2	94	No
voice	2	3	2	47	No

Example

The following example configures an EDCA profile for APs:

```
(host) [/md] (config) #wlan edca-parameters-profile ap edca1
(host) [/md] (EDCA Parameters profile (AP) "edca1") #best-effort ecw-min 15
ecw-max 15 aifsn 15 txop 100 acm 1
```

wlan he-ssid-profile

```
wlan he-ssid-profile <profile-name>
  clone
  dynamic-fragmentation-level <dynamic-fragmentation-level>
  he-duration-based-rts <he-duration-based-rts>
  he-guard-interval
  he-mu-mimo
  he-mu-ofdma
  he-supported-mcs-map <he-supported-mcs-map>
  he-ul-mu-mimo
  he-txbf
  high-efficiency-enable
  individual-twt
  no...
```

Description

This command configures a high-efficiency SSID profile.

Parameter	Description
<profile-name>	Name of this instance of the profile. 1-63 characters default
clone	Name of an existing high-efficiency SSID profile from which parameter values are copied.
dynamic-fragmentation-level	Controls the level of dynamic fragmentation that is supported by the APs. Enter one of the following values: <ul style="list-style-type: none">0: Does not support Dynamic Fragmentation1: Support for dynamic fragments that are contained within an S-MPDU. It does not support dynamic fragment within an A-MPDU that is not an S-MPDU.2: Support for dynamic fragments that are contained within an S-MPDU, and support for up to one dynamic fragment for each MSDU within an A-MPDU.3: Support for dynamic fragments that are contained within an S-MPDU, and support for up to four dynamic fragments for each MSDU within an A-MPDU. 0-3 0
he-duration-based-rts	Indicates the duration-based RTS value, in microseconds, in the HE capability. When the Transmission Opportunity (TXOP) is greater than the configured duration-based RTS value, RTS/CTS exchange value is used. 0-1023

Parameter	Description
	1023
he-guard-interval	Sets the supported GI. 800 ns, 1600 ns, 3200 ns 800
he-mu-mimo	Enables or disables HE MU-MIMO in WLAN high-efficiency SSID. enabled
he-mu-ofdma	Enables or disables HE MU-OFDMA in WLAN high-efficiency SSID. enabled
he-supported-mcs-map	Comma separated list of maximum supported MCS for spatial streams 1 through 8. Valid values for maximum MCS are 7, 9, 11, and '-' (if spatial stream is not supported). Maximum MCS of a spatial stream cannot be higher than the previous streams. If an MCS is not valid for a particular combination of bandwidth and number of spatial streams, it is not used for Tx and Rx. 7,9,11, - 11,11,11,11,11,11,11,11
he-ul-mu-mimo	Enables uplink MU-MIMO in HE capability. NOTE: Only AP-535 and AP-555 access points support uplink MU-MIMO transmission.
he-txbf	Enables or disables Transmit Beamforming (TxBF) in HE capability. enabled
high-efficiency-enable	Enables or disables high-efficiency (802.11ax) features in SSID. enabled
individual-twt	Enables or disables individual TWT support. enabled
no	Negates any configured parameter.

Example

The following example configures the dynamic fragmentation level supported by the AP for the default high-efficiency SSID:

```
(host) [md] (config) #wlan he-ssid-profile default
(host) [md] (High-efficiency SSID profile "default") #dynamic-fragmentation-
level 2
```

Description

This command configures a WLAN advertisement profile for an 802.11u public access service provider.

Hotspot 2.0 is a WFA specification based upon the 802.11u protocol that provides wireless clients with a streamlined mechanism to discover and authenticate to suitable networks, and allows mobile users the ability to roam between partner networks without additional authentication.

Access Network Query Protocol (ANQP) and Hotspot 2.0 Query Protocol (H2QP) profiles define the information in the 802.11u IEs to be broadcast by an 802.11u-capable AP. Use this command to select one of each type of ANQP and H2QP profile to be associated with the advertisement profile.

Values configured in the ANQP profiles will not be sent to clients unless you:

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<code>anqp-3gpp-nwk-profile <profile-name></code>	Name of the Access Network Query Protocol (ANQP) 3GPP cellular network profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-3gpp-nwk-profile on page 4139 .

Parameter	Description
anqp-domain-name-profile <profile-name>	Name of the ANQP domain name profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-domain-name-profile on page 4141 .
anqp-ip-addr-avail-profile <profile-name>	Name of the ANQP IP Address Availability profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-ip-addr-avail-profile on page 4143 .
anqp-nai-realm-profile <profile-name>	Name of the ANQP NAI Realm profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-nai-realm-profile on page 4145 .
anqp-nwk-auth-profile <profile-name>	Name of the ANQP Network Authentication profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-nwk-auth-profile on page 4150 .
anqp-roam-cons-profile <profile-name>	Name of the ANQP Roaming Consortium profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-roam-cons-profile on page 4152 .
anqp-venue-name-profile <profile-name>	Name of the ANQP Venue Name profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot anqp-venue-name-profile on page 4154 .
clone <profile-name>	Make a copy of an existing WLAN Advertisement profile.

Parameter	Description
h2qp-conn-cap-profile <profile-name>	Name of the Hotspot 2.0 Connection Capability profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot h2qp-conn-capability-profile on page 4157 .
h2qp-op-cl-profile <profile-name>	Name of the Hotspot 2.0 Operating Class Indication profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot h2qp-op-cl-profile on page 4159 .
h2qp-operator-friendly-name-profile <profile-name>	Name of the Hotspot 2.0 operator-friendly name profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot h2qp-operator-friendly-name-profile on page 4161 .
h2qp-osu-prov-list-profile <profile-name>	Name of the Hotspot 2.0 OSU providers list profile to be associated with this WLAN advertisement profile.
h2qp-wan-metrics-profile <profile-name>	Name of the Hotspot 2.0 WAN Metrics profile to be associated with this WLAN advertisement profile. For more information on configuring this profile, refer to wlan hotspot h2qp-wan-metrics-profile on page 4167 .
no	Negate or remove any existing parameter, returning it to its default value.
osu-ssid	NAme of the OSU SSID..

Example

The following example associates the ANQP domain name profile **anqp-dom-1** to the advertisement profile **network1**:

```
(host) [mynode] (config) #wlan hotspot advertisement-profile network1
```

```
(host) [mynode] (Advertisement Profile "network1") #anqp-domain-name-profile  
anqp-dom-1
```

Related Commands

Command	Description

  3gpp_plmn6 <3GPP-PLMN6>  
  clone <source>  
no
```

Description

This command defines information for a 3GPP Cellular Network for hotspots that have roaming relationships with cellular operators.

The 3GPP Cellular Network Profile defines an ANQP information element (IE) to be sent in a Generic Advertisement Service (GAS) query response from an AP in a hotspot with a roaming relationship with a cellular operator. The 3GPP Mobile Country Code (MCC) and the 12-bit Mobile Network Code data in the IE can help the client select a 3GPP network.

Values configured in this profile will not be sent to clients unless you:

Associate the 3GPP Cellular Network profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-3gpp-nwk-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. ("`wlan hotspot h2-profile advertisement-profile <profile-name>` ")

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
3gpp_plmn1	The Public Land Mobile Networks (PLMN) value of the highest-priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp_plmn2	The Public Land Mobile Networks (PLMN) value of the second-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp_plmn3	The Public Land Mobile Networks (PLMN) value of the third-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp_plmn4	The Public Land Mobile Networks (PLMN) value of the fourth-highest priority network.

Parameter	Description
	The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp_plmn5	The Public Land Mobile Networks (PLMN) value of the fifth-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
3gpp_plmn6	The Public Land Mobile Networks (PLMN) value of the sixth-highest priority network. The PLMN is comprised of a 12-bit Mobile Country Code (MCC) and the 12-bit Mobile Network Code (MNC).
clone <profile-name>	Copies an existing 3GPP profile.
no	Removes an existing parameter.

Example

The following example defines 3GPP data for the 3GPP profile **cellcorp1**:

```
(host) [md] (config) #wlan hotspot anqp-3gpp-nwk-profile cellcorp1
(host) [md] ((ANQP 3GPP Cellular Network Profile "cellcorp1") #enable
(host) [md] ((ANQP 3GPP Cellular Network Profile "cellcorp1") #3gpp_plmn1
310026
(host) [md] ((ANQP 3GPP Cellular Network Profile "cellcorp1") #3gpp_plmn2
208000
(host) [md] ((ANQP 3GPP Cellular Network Profile "cellcorp1") #3gpp_plmn3
208001
```

wlan hotspot anqp-domain-name-profile

```
wlan hotspot anqp-domain-name-profile <profile-name>
  clone <source>
  domain-name <domain-name>
no
```

Description

This command defines the domain name to be sent in an Access Network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response. If a client uses the Generic Advertisement Service (GAS) to post an ANQP query to an Access Point, the AP will return an ANQP Information Element with the domain name configured in this profile.

Values configured in this profile are not sent to clients unless you:

Associate the ANQP Domain Name profile with an ANQP advertisement profile (`wlan hotspot advertisement profile <profile-name> anqp-domain-name-profile <profile-name>`).

Associate the ANQP advertisement profile with a Hotspot profile (`wlan hotspot h2-profile advertisement-profile <profile-name>`).

Enable the hotspot feature within that Hotspot profile (`wlan hotspot h2-profile <profile-name> hotspot-enable`).

Parameter	Description
<profile-name>	ANQP domain name profile.
clone <source>	Copies an existing ANQP domain name profile.
domain-name <domain-name>	Domain name of the hotspot operator. This alphanumeric string must be 255 characters or less.
no	Removes an existing parameter.

Example

The following example defines a domain name for the ANQP domain name profile domain1:

```
(host) [md] (config) #wlan hotspot anqp-domain-name-profile domain1
(host) [md] (ANQP Domain Name Profile "domain1") #domain-name example.com
```

wlan hotspot anqp-ip-addr-avail-profile

```
wlan hotspot anqp-ip-addr-avail-profile <profile-name>
  clone <profile-name>
  ipv4-addr-avail {availability-unknown|not-available|port-restricted|port-
  restricted-double-nated|port-restricted-single-nated|private-double-
  nated|private-single-nated|public}
  ipv6-addr-avail {available|availability-unknown|not-available}
no
```

Description

This command defines available IP address types to be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response. The IP Address Availability information configured using this command provides clients with information about the availability of IP address versions and types which could be allocated to those clients after they associate to the hotspot AP.

Values configured in this profile will not be sent to clients unless you:

Associate the ANQP IP Address Availability profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-ip-addr-avail-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile-name>	Name of the ANQP IP address availability profile.
clone <source>	Copies an existing ANQP IP Address Availability profile.
ipv4-addr-avail	Indicates the availability of an IPv4 network.
availability-unknown	Network availability cannot be determined.
not-available	Network is not available.
port-restricted	Network has some ports restricted (for example, the network blocks port 110 to restrict POP mail).
port-restricted-double-nated	Network has some ports restricted and multiple routers performing network address translation.
port-restricted-single-nated	Network has some ports restricted and a single router performing network address translation.

Parameter	Description
private-double-nated	Network is a private network with multiple routers doing network address translation.
private-single-nated	Network is a private network a single router doing network address translation.
public	Network is a public network.
ipv6-addr-avail	Indicates the availability of an IPv6 network.
available	An IPv6 network is available.
availability-unknown	Network availability cannot be determined.
not-available	Network is not available.
no	Removes an existing parameter.

Example

The following example configures an AP using this profile to advertise a public IPv4 network:

```
(host) [md] (config) #wlan hotspot anqp-ip-addr-avail-profile default
(host) [md] (ANQP IP Address Availability Profile "default") #ipv4-addr-avail public
(host) [md] (ANQP IP Address Availability Profile "default") #ipv6-addr-avail not-available
```

  card|identity|notification|one-time-password|peap|peap-mschapv2
  nai-realm-encoding <nai-realm-encoding>
  nai-realm-name <nai-realm-name>
  no
```

Description

This command defines a Network Access Identifier (NAI) realm whose information can be sent as an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

An AP's NAI Realm profile identifies and describes a NAI realm accessible using the AP, and the method that this NAI realm uses for authentication. These settings configured in this profile determine the NAI realm elements that are included as part of a GAS Response frame.

Values configured in this profile will not be sent to clients unless you:

Associate the ANQP NAI Realm profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name>anqp-nai-realm-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profileadvertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name>hotspot-enable`)

Parameter	Description
<profile-name>	Name of the ANQP NAI realm profile.
clone <source>	Copies an existing NAI Realm profile.

Parameter	Description
nai-home-realm	Marks the realm in this profile as the NAI Home Realm.
nai-realm-auth-id-1 nai-realm-auth-id-2	Use the <code>nai-realm-auth-id-1</code> command to send the one of the following authentication methods for the primary NAI realm ID. Use the <code>nai-realm-auth-id-2</code> command to send the one of the following authentication methods for the secondary NAI realm ID.
credential-type	The specified authentication ID uses credential authentication.
expanded-eap	The specified authentication ID uses the expanded EAP authentication method.
expanded-inner-eap	The specified authentication ID uses the expanded inner EAP authentication method.
inner-auth-eap	The specified authentication ID uses inner EAP authentication type.
non-eap-inner-auth	The specified authentication ID uses non-EAP inner authentication type.
reserved	The specified authentication ID uses Reserved authentication type.
tunneled-eap-credential-type	The specified authentication ID uses the tunneled EAP credential type.
nai-realm-auth-value-1 nai-realm-auth-value-2	Use the <code>nai-realm-auth-value-1</code> command to select an authentication value for the authentication method specified by nai-realm-auth-id-1 . Use the <code>nai-realm-auth-value-2</code> command to select the authentication value for the authentication method specified by nai-realm-auth-id-2 .
cred-cert	Credential - Certificate.
cred-hw-token	Credential - Hardware Token.
cred-nfc	Credential - NFC.
cred-none	Credential - None.
cred-rsvd	Credential - Reserved.

Parameter	Description
cred-sim	Credential - SIM.
cred-soft-token	Credential - Soft Token.
cred-user-pass	Credential - Username and password.
cred-usim	Credential - USIM.
cred-vendor-spec	Credential - Vendor-specific.
eap-crypto-card	EAP Method - Crypto-card.
eap-generic-token-card	EAP Method - Generic-Token-Card.
eap-identity	EAP Method - Identity.
eap-method-aka	EAP Method - AKA.
eap-method-sim	EAP Method - SIM - GSM Subscriber Iden.
eap-method-tls	EAP Method - TLS - Transport Layer Sec.
eap-method-ttls	EAP Method - TTLS - Tunneled Transport Security.
eap-notification	EAP Method - Notification.
eap-one-time-password	EAP Method - One-Time-Password.
eap-peap	EAP Method - PEAP.
eap-peap-mschapv2	EAP Method - PEAP MSCHAP V2.
non-eap-chap	Non-EAP Method - CHAP.
non-eap-mschap	Non-EAP Method - MSCHAP.
non-eap-mschapv2	Non-EAP Method - MSCHAPv2.
non-eap-pap	Non-EAP Method - PAP.
non-eap-rsvd	Non-EAP Method - Reserved for future use.
reserved	Reserved for future use.
tun-cred-anon	Tunneled Credential - ANONYMOUS.
tun-cred-cert	Tunneled Credential - CERTIFICATE .
tun-cred-hw-token	Tunneled Credential - Hardware Token.

Parameter	Description
tun-cred-nfc	Tunneled Credential - NFC.
tun-cred-rsvd	Tunneled Credential - RESERVED.
tun-cred-sim	Tunneled Credential - SIM.
tun-cred-soft-token	Tunneled Credential - Soft Token.
tun-cred-user-pass	Tunneled Credential - USERNAME and PASSWORD.
tun-cred-usim	Tunneled Credential - USIM.
tun-cred-vendor-spec	Tunneled Credential - VENDOR SPECIFIC.
nai-realm-eap-method	Select one of the options below to identify the EAP authentication method supported by the hotspot realm.
crypto-card	Crypto card authentication.
eap-aka	EAP for UMTS Authentication and Key Agreement.
eap-sim	EAP for GSM Subscriber Identity Modules.
eap-tls	EAP-Transport Layer Security.
eap-ttls	EAP-Tunneled Transport Layer Security.
generic-token-card	EAP Generic Token Card (EAP-GTC)
identity	EAP Identity type.
notification	The hotspot realm uses EAP Notification messages for authentication.
one-time-password	Authentication with a single-use password.
peap	Protected Extensible Authentication Protocol.
peap-mschapv2	Protected Extensible Authentication Protocol with Microsoft CHAP version 2.
nai-realm-encoding <nai-realm-encoding>	Issue this command if the NAI realm named defined by nai-realm-name <nai-realm-name> is a UTF-8 formatted character string that is not formatted in accordance with IETF RFC 4282.
nai-realm-name <nai-realm-name>	Name of the NAI realm. The realm name is often the domain name of the service provider.
no	Negates or removes any existing parameter

Example

The following example configures a Network Access Identifier (NAI) realm profile:

```
(host) [md] (config) #wlan hotspot anqp-nai-realm-profile home
(host) [md] (ANQP NAI Realm Profile "home") #enable
(host) [md] (ANQP NAI Realm Profile "home") #nai-realm-name corp-hotspot.com
(host) [md] (ANQP NAI Realm Profile "home") #nai-realm-auth-id-1 credential-
type
(host) [md] (ANQP NAI Realm Profile "home") #nai-realm-auth-value-1 cred-
cert
(host) [md] (ANQP NAI Realm Profile "home") #nai-home-realm
(host) [md] (config) #wlan hotspot anqp-nai-realm-profile non-home
(host) [md] (ANQP NAI Realm Profile "non-home") #nai-realm-name corp-
hotspot-roam.com
(host) [md] (ANQP NAI Realm Profile "non-home") #nai-realm-eap-method eap-
sim
(host) [md] (ANQP NAI Realm Profile "non-home") #nai-realm-auth credential-
type
```

Command History

wlan hotspot anqp-nwk-auth-profile

```
wlan hotspot anqp-nwk-auth-profile <profile-name>
  clone <source>
  no
  nwk-auth-type {acceptance|dns-redirection|http-https-redirection|online-enroll}
  url <url>
```

Description

This command configures an ANQP Network Authentication profile to define authentication type being used by the hotspot network.

When you enable the [asra](#) option in the WLAN hotspot profile, the settings you configure in the Network Authentication profile are sent in the GAS response to the client.

Values configured in this profile will not be sent to clients unless you:

Associate the ANQP Network Authentication profile an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-nwk-auth-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile-name>	Name of the ANQP network authentication profile.
clone <source>	Copies an existing ANQP Network Authentication profile.
no	Negates any existing parameter.
nwk-auth-type	Network authentication type being used by the hotspot network.
acceptance	Network requires the user to accept terms and conditions. NOTE: This option requires you to specify a redirection URL string as an IP address, FQDN or URL.
dns-redirection	Additional information on the network is provided through DNS redirection. NOTE: This option requires you to specify a redirection URL string as an IP address, FQDN or URL.

Parameter	Description
http-https-redirect	Additional information on the network is provided through HTTP or HTTPS redirection.
online-enroll	Network supports online enrollment.
url <url>	URL, IP address, or FQDN used by the hotspot network for the acceptance or dns-redirect network authentication types.

Example

The following example configures the default Network Authorization profile to use DNS redirection:

```
(host) [md] (config) #wlan hotspot anqp-nwk-auth-profile default
(host) [md] (ANQP Network Authentication Profile "default") #nwk-auth-type
dns-redirect redirect-url http://www.example.com/redirect.html
```

wlan hotspot anqp-roam-cons-profile

```
wlan hotspot anqp-roam-cons-profile <profile-name>  
  clone <source>  
  no  
  roam-cons oi <oi>
```

Description

This command configures the Roaming Consortium OI information to be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

Organization Identifiers (OIs) are assigned to service providers when they register with the IEEE registration authority. The Roaming Consortium IEs contain information identifying the network and service provider, whose security credentials can then be used to authenticate with the AP transmitting this element.

Use the [wlan hotspot anqp-roam-cons-profile](#) command to define the OI for the hotspot service provider in the ANQP Roaming Consortium profile. Values configured in this profile will not be sent to clients unless you:

Associate the ANQP Roaming Consortium profile an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-roam-cons-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

NOTE

To identify additional Roaming consortium OIs used by the service provider's top three roaming partners, configure the [wlan hotspot hs2-profile](#), [wlan hotspot hs2-profile](#) or [wlan hotspot hs2-profile](#) parameters in the Hotspot Profile.

Parameter	Description
<profile-name>	Name of the ANQP roaming consortium profile.
clone <source>	Copies an existing ANQP Roaming Consortium profile.
no	Negates any existing parameter.
roam-cons oi <oi>	Sends the specified roaming consortium OI in a GAS query response. The OI must be a hexadecimal value.

Example

The following example defines the roaming consortium OI and OI length in the ANQP roaming consortium profile:

```
(host) [md] (config) #wlan hotspot anqp-roam-cons-profile profile1
(host) [md] (ANQP Roaming Consortium Profile "profile1") #roam-cons oi
506F9A
(host) [md] (ANQP Roaming Consortium Profile "profile1") #roam-cons-oi-len 3
```

Command History

wlan hotspot anqp-venue-name-profile

```
wlan hotspot anqp-venue-name-profile <profile-name>
  clone
  no
  venue-group {outdoor|reserved|utility-
misc|vehicular|assembly|business|educational|factory-or-
industrial|institutional|mercantile|residential|storage|unspecified|utility-
misc|vehicular}
  venue-lang-code <venue-lang-code>
  venue-name <venue-name>
  venue-name-hex <venue-name-hex>
  venue-type <venue-type>
  venue-url <venue-url>
```

Description

This command defines venue information be sent in an Access network Query Protocol (ANQP) information element in a Generic Advertisement Service (GAS) query response.

Use this command to configure the venue group and venue type in an ANQP Venue Name profile. If a client uses the Generic Advertisement Service (GAS) to post an ANQP query to an Access Point, the AP will return ANQP Information Elements with the values configured in this profile.

Values configured in this profile will not be sent to clients unless you:

Associate the ANQP Venue Name profile with an ANQP Advertisement profile. (`wlan hotspot advertisement profile <profile-name> anqp-venue-name-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile-name>	Name of the ANQP venue profile.
clone <source>	Copies an existing ANQP Venue Name profile.
no	Negates any existing parameter.
venue-group	Specify one of the following venue groups to be advertised in the ANQP IEs from APs associated with this profile. The default setting is unspecified. <ul style="list-style-type: none">■ assembly■ business■ educational■ factory-or-industrial■ institutional■ mercantile

Parameter	Description
	<ul style="list-style-type: none"> ■ outdoor ■ reserved ■ residential ■ storage ■ unspecified ■ utility-misc ■ vehicular
venue-lang-code <venue-lang-code>	An ISO 639 language code that identifies the language used in the Venue Name field.
venue-name <venue-name>	Venue name to be advertised in the ANQP IEs from APs associated with this profile. If the venue name includes spaces, the name must be enclosed in quotation marks, e.g. "Midtown Shopping Center".
venue-name-hex <venue-name-hex>	Venue name, in hex format, to be advertised in the ANQP IEs from APs associated with this profile.
venue-type <venue-type>	Specify a venue type to be advertised in the IEs from APs associated with this hotspot profile. The complete list of supported venue types is described in Venue Types on page 4155 .
venue-url <venue-url>	Venue URL where customer may go to get additional information related to the venue.

Venue Types

The following list describes the different venue types that may be configured in a hotspot profile:

<ul style="list-style-type: none"> ■ assembly-amphitheater ■ assembly-amusement-park ■ assembly-arena ■ assembly-bar ■ assembly-coffee-shop ■ assembly-convention-center ■ assembly-emer-coord-center ■ assembly-library ■ assembly-museum ■ assembly-passenger-terminal ■ assembly-restaurant 	<ul style="list-style-type: none"> ■ business-police-station ■ business-post-office ■ business-professional-office ■ business-research-and-development ■ business-unspecified ■ educational-primary-school ■ educational-secondary-school ■ educational-university ■ educational-unspecified ■ industrial-factory ■ institutional-alcohol-or-drug-rehab ■ institutional-group-home 	<ul style="list-style-type: none"> ■ merchantile unspecified ■ outdoor-bus-stop ■ outdoor-city-park ■ outdoor-kiosk ■ outdoor-muni-mesh-nwk ■ outdoor-rest-area ■ outdoor-traffic-control ■ outdoor-unspecified ■ residential-boarding-house ■ residential-dormitory ■ residential-hotel ■ residential-private-residence
---	--	--

<ul style="list-style-type: none"> ■ assembly-stadium ■ assembly-theater ■ assembly-unspecified ■ assembly-worship-place ■ assembly-zoo ■ business-attorney ■ business-bank ■ business-doctor ■ business-fire-station 	<ul style="list-style-type: none"> ■ institutional-hospital ■ institutional-prison ■ institutional-terminal-care ■ institutional-unspecified ■ mercantile-automotive-service-station ■ mercantile-gas-station ■ mercantile-grocery ■ mercantile-retail ■ mercantile-shopping-mall 	<ul style="list-style-type: none"> ■ residential-unspecified ■ unspecified ■ vehicular-airplane ■ vehicular-automobile ■ vehicular-bus ■ vehicular-ferry ■ vehicular-motor-bike ■ vehicular-ship ■ vehicular-train ■ vehicular-unspecified
--	--	--

Example

The following example defines an ANQP Venue Name profile for a shopping mall:

```
(host) [md] (config) #wlan hotspot anqp-venue-name-profile Mallprofile1
(host) [md] (ANQP Venue Name Profile "Mallprofile1") #venue-group mercantile
(host) [md] (ANQP Venue Name Profile "Mallprofile1") #venue-name Westgate Shopping Center

(host) [md] (ANQP Venue Name Profile "Mallprofile1") #venue-type mercantile-shopping-mall
```

Command History

Release	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Config mode on Mobility Conductor.

wlan hotspot h2qp-conn-capability-profile

```
wlan hotspot h2qp-conn-capability-profile <profile-name>
  clone <source>
  esp
  icmp
  no
  tcp-ftp
  tcp-http
  tcp-pptp-vpn
  tcp-ssh
  tcp-tls-vpn
  tcp-voip
  udp-ike2-4500
  udp-ike2-500
  udp-voip
```

Description

This command defines an H2QP profile that advertises hotspot protocol and port capabilities. The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about the IP protocols and associated port numbers that are available and open for communication.

Values configured in this profile will not be sent to clients unless you:

Associate the H2QP profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> h2qp-conn-cap-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile-name>	Name of the H2QP connection capability profile.
clone <source>	Copies an existing hotspot connection capability profile.
esp	Include this parameter to enable the Encapsulating Security Payload (ESP) port used by IPsec VPNs. (port 0)
icmp	Indicates that the ICMP port is enabled and available. (port 0)
no	Negates any existing parameter, returning it to its default disabled value.
tcp-ftp	Include this parameter to enable the FTP port. (port 20)

Parameter	Description
tcp-http	Include this parameter to enable the HTTP port. (port 80)
tcp-pptp-vpn	Include this parameter to enable the PPTP port used by IPsec VPNs. (port 1723)
tcp-ssh	Include this parameter to enable the SSH port. (port 22)
tcp-tls-vpn	Include this parameter to enable the TCP TLS port used by VPNs. (port 80)
tcp-voip	Include this parameter to enable the TCP VoIP port. (port 5060)
udp-ike2-4500	Include this parameter to enable the IKEv2. (port 4500)
udp-ike2-500	Include this parameter to enable the IKEv2. (port 500)
udp-voip	Include this parameter to enable the UDP VoIP port. (port 5060)

Example

The following example allows the H2QP connection capability profile to advertise the availability of ICMP, HTTP, and VOIP ports:

```
(host) [md] (config) #wlan hotspot h2qp-conn-capability-profile Wan1
(host) [md] (H2QP Connection Capability Profile "Wan1") #icmp
(host) [md] (H2QP Connection Capability Profile "Wan1") #http
(host) [md] (H2QP Connection Capability Profile "Wan1") # voip
(host) [md] (H2QP Connection Capability Profile "Wan1") #enable
```

wlan hotspot h2qp-op-cl-profile

```
wlan hotspot h2qp-op-cl-profile <profile-name>
  clone <source>
  no
  op-cl <op-cl>
```

Description

This command defines an H2QP profile that defines the Operating Class to be sent in the ANQP IE.

The values configured in this H2QP Operating Class profile define the channels on which the hotspot is capable of operating. It may be useful where, for instance, a mobile device discovers a hotspot in the 2.4 GHz band but finds it is dual-band and prefers the 5 GHz band. For a definition of these global operating classes, refer to Table E-4 of IEEE Std 802.11-2012, Annex E.

Values configured in this profile will not be sent to clients unless you:

Associate the H2QP profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name> h2qp-op-cl-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name> hotspot-enable`)

Parameter	Description
<profile-name>	Name of the H2QP operating class indication profile.
clone <source>	Copies an existing hotspot operating class profile.
no	Negates any existing parameter, returning it to its default disabled value.
op-cl <op-cl>	Configures the operating class for the devices' BSS. 1-255 1

Example

The following example configures and enables a profile with the default operating class value:

```
(host) [md] (config) #wlan hotspot h2qp-op-cl-profile profile1
(host) [md] (H2QP Operating Class Indication Profile "profile1") #op-cl 1
(host) [md] (H2QP Operating Class Indication Profile "profile1") #enable
```

wlan hotspot h2qp-operator-friendly-name-profile

```
wlan hotspot h2qp-operator-friendly-name-profile <profile-name>
  clone <source>
  no
  op-fr-name <op-fr-name>
  op-fr-name-hex <op-fr-name-hex>
  op-lang-code <op-lang-code>
```

Description

This command defines an H2QP operator-friendly name profile.

The operator-friendly name configured in this profile is a free-form text field that can identify the operator and also something about the location.

Values configured in this profile will not be sent to clients unless you:

Associate the H2QP operator-friendly name profile with an ANQP advertisement profile. (`wlan hotspot advertisement profile <profile-name>h2qp-operator-friendly-profile <profile-name>`)

Associate the ANQP advertisement profile with a Hotspot profile. (`wlan hotspot h2-profile advertisement-profile <profile-name>`)

Enable the hotspot feature within that Hotspot profile. (`wlan hotspot h2-profile <profile-name>hotspot-enable`)

Parameter	Description
<profile-name>	H2QP operator friendly name profile.
clone <source>	Copies an existing operator-friendly name profile.
no	Negates any existing parameter.
op-fr-name <op-fr-name>	An operator-friendly name sent by devices using this profile. The name can be up to 64 alphanumeric characters, and can include special characters and spaces. If the name includes quotation marks ("), you must include a backslash character (\) before each quotation mark. (e.g. \"example\")
op-fr-name-hex <op-fr-name-hex>	Operator Friendly Name in HEX.
op-lang-code <op-lang-code>	An ISO 639 language code that identifies the language used in the op-fr-name field.

Example

The following example shows that the managed device has two configured operator friendly name profiles. The **References** column lists the number of other profiles with references to the

operator friendly name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) [md] (config) #wlan hotspot h2qp-operator-friendly-name-profile
profile1
(host) [md] (H2QP Operator Friendly Name Profile "profile1") #op-fr-name my_
hotspot
(host) [md] (H2QP Operator Friendly Name Profile "profile1") #op-lang-code
<op-lang-code>
```

  srvcdesc-count <count>
```

Description

This command configures a H2QP profile that defines the Open Sign-Up(OSU) provider details to be sent in the H2QP IE.

Parameter	Description
disable	Disables the OSU provider profile.
enable	Enables the OSU provider profile. enabled
frnd-name-count	Number of OSU friendly names to be configured. 1-2

Parameter	Description
<code>frnd-name1</code>	The first OSU friendly name if you selected the language code as English. A string value of maximum 64 characters.
<code>frnd-name1-hex</code>	The first OSU friendly name in hexadecimal format for language codes other than English.
<code>frnd-name1-lang-code</code>	The language code used for configuring the first OSU friendly name.
<code>frnd-name2</code>	The second OSU friendly name if the language code chosen is English. A string value of maximum 64 characters.
<code>frnd-name2-hex</code>	The second OSU friendly name in hexadecimal format for language codes other than English.
<code>frnd-name2-lang-code</code>	The language code used for configuring the second OSU friendly name.
<code>icon1-file</code>	The index and name of the first icon image file.
<code>icon1-height</code>	Height of the first icon image file.
<code>icon1-lang-code</code>	Indicates the language used in the first icon image.
<code>icon1-type</code>	Type of the image file used as first icon.
<code>icon1-width</code>	Width of the first icon image file. 1-256
<code>icon2-file</code>	The index and name of the second icon image file.
<code>icon2-height</code>	Height of the second icon image file.
<code>icon2-lang-code</code>	Indicates the language used in the second icon image.
<code>icon2-type</code>	Type of the image file used as second icon.
<code>icon2-width</code>	Width of the second icon image file.
<code>iconfile-count</code>	Number of icon files to be used for the OSU provider. 1-2
<code>no</code>	Deletes the command.
<code>osu-method</code>	Indicates the method used by OSU to provision the HS2 client. OMA-DM, SOAP-XML
<code>osu-server-uri</code>	The URI of the OSU Server that is used for OSU with the service provider configured in the <code>frnd-name1</code> parameter.

Parameter	Description
srvc-desc1	The first service description if you selected the language code as English.
srvc-desc1-hex	The first service description in hexadecimal format for language codes other than English.
srvc-desc1-lang-code	The language code used for the first description.
srvc-desc2	The second service description if you selected the language code as English.
srvc-desc2-hex	The second service description in hexadecimal format for language codes other than English.
srvc-desc2-lang-code	The second service description if you selected the language code as English.
srvcdesc-count	Number of descriptions to be provided for the OSU provider.

Example

The following example creates and configures an OSU provider profile:.

```
(host) (config) # hotspot h2qp-osu-provider-profile OSU
(host) [mynode] (H2QP OSU Providers List Profile "OSU") # frnd-name-count 2

wlan hotspot h2qp-wan-metrics-profile

```
wlan hotspot h2qp-wan-metrics-profile <profile-name>
  at-capacity
  clone <source>
  downlink-load
  downlink-speed
  load-dur
  no
  symm-link
  uplink-load
  uplink-speed
  wan-metrics-link-status link_down|link_test|link_up|reserved
```

Description

This command creates an H2QP profile that specifies the hotspot WAN status and link metrics. The values configured in this profile can be sent in an ANQP IE to provide hotspot clients information about access network characteristics such as link status and the capacity and speed of the WAN link to the Internet. Issue this command without the `<profile-name>` parameter to display the entire WAN metrics profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Parameter	Description
<code><profile-name></code>	Name of the H2QP WAN metrics profile.
<code>at_capacity</code>	Use the <code>at_capacity</code> parameter to indicate that the WAN Link has reached its maximum capacity. If this parameter is enabled, no additional mobile devices will be permitted to associate with the hotspot AP. enabled, disabled disabled
<code>clone <source></code>	Copies an existing H2QP profile.
<code>downlink-load <load></code>	The percentage of the WAN downlink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified. 1-100 0 (unspecified)

Parameter	Description
downlink-speed <speed>	Use the <code>downlink_speed <speed></code> parameter to indicate the current WAN backhaul downlink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified. 0 - 2,147,483,647 Kbps 0 (unspecified)
load-dur <load_dur>	Duration over which the downlink load is measured, in tenths of a second. 0 and 65535
no	Negates any existing parameter
symm-link	Use the <code>symn_link</code> parameter to indicate that the WAN Link has same speed in both the uplink and downlink directions. enabled, disabled disabled
uplink-load <speed>	The percentage of the WAN uplink that is currently utilized. If no value is set, this parameter will show a default value of 0 to indicate that the downlink speed is unknown or unspecified. 1-100 0 (unspecified)
uplink-speed <speed>	Use the <code>uplink <speed></code> parameter to indicate the current WAN backhaul uplink speed in Kbps. If no value is set, this parameter will show a default value of 0 to indicate that the uplink speed is unknown or unspecified. 0 - 2,147,483,647 Kbps 0 (unspecified)
wan-metrics-link-status	Define the status of the WAN Link by configuring one of the following values. The default link status is reserved , which indicates that the link status is unknown or unspecified. link_down, link_test, link_up, reserved reserved
link_down	WAN link is down.
link_test	WAN link is currently in a test state.
link_up	WAN link is up.
reserved	This parameter is reserved by the Hotspot 2.0 specification, and cannot be configured. This is the default link status.

Example

The following example shows three WAN metrics profiles that are configured. The **References** column lists the number of other profiles with references to the operator-friendly name profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) [md] #show wlan hotspot h2qp-wan-metrics-profile
H2QP WAN Metrics Profile List
-----
Name           References  Profile Status
----           -
default        0

  time-zone <time-zone>
  venue-group <venue-group>
  venue-type <venue-type>
```

Description

This command configures a hotspot profile for an 802.11u public access service provider.

Hotspot 2.0 is a WFA specification based upon the 802.11u protocol that provides wireless clients with a streamlined mechanism to discover and authenticate to suitable networks, and allows mobile users the ability to roam between partner networks without additional authentication.

Mobility Conductor supports Hotspot 2.0 with enhanced network discovery and selection. Clients can receive general information about the network identity, venue and type via management frames from the Aruba AP. Clients can also query APs for information about the network's

available IP address type (IPv4 or IPv6), roaming partners, and supported authentication methods, and receive that information in Information Elements from the AP.

Parameter	Description
<profile-name>	Name of the hotspot profile.
access-network-type	Specifies the 802.11u network type. The default setting is public-chargeable . <ul style="list-style-type: none"> ■ emergency-services: emergency services only network ■ personal-device: personal device network ■ private: private network ■ private-guest: private network with guest access ■ public-chargeable: public chargeable network ■ public-free: free public network ■ test: test network ■ wildcard: wildcard network
advertisement-profile <profile-name>	Advertisement profile associated with this hotspot profile. If this parameter is not changed, the hotspot profile uses with the default advertisement profile.
advertisement-protocol	Select one of the following advertisement protocol types to be used by the AP. <ul style="list-style-type: none"> ■ anqp ■ emergency: Emergency Alert System ■ mih-cmd-event: Media Independent Handover Command and Event Services Capability Discovery ■ mih-info: Media Independent Handover Information Service. This option allows handovers between differing kinds of wireless access protocols and technologies, allowing access points on different IP subnets to communicate with each other at the link level while maintaining session continuity. ■ rsvd: Reserved for future use.
anqp-domain-id <anqp-domain-id>	Number representing the ANQP Domain ID. Zero means no domain.
asra	Issue the Additional Steps Required for Access (ASRA) sub command if any additional steps are required for network access. If this parameter is enabled, the AP will send the following IEs in response to the client's ANQP query. <ul style="list-style-type: none"> ■ Venue Name ■ Domain Name List ■ Network Authentication Type ■ Roaming Consortium List ■ NAI Realm List <p>NOTE: If ASRA is enabled, the advertisement profile for this hotspot must reference an enabled network</p>

Parameter	Description
	authentication type profile. For more information on enabling an network authentication type profile, see wlan hotspot anqp-nwk-auth-profile on page 4150 .
clone <source>	Makes a copy of an existing hotspot profile.
comeback-mode	By default, ANQP information is obtained from a GAS Request and Response. If you enable the comeback-mode option, advertisement information is obtained using a GAS Request and Response, as well as a Comeback-Request and Comeback-Response. This option is disabled by default.
dscp-exceptions <dscp-exceptions>	QoS Map DSCP Exception fields. These can be upto 21 sets <value>:<up> separated by ',' where value is 0-3F or FF, and up is 0-7) Format Example: DSCP:UP[,DSCP:UP]
dscp-ranges	QoS Map DSCP Ranges. There are total 8 sets <low>:<high> separated by ',' where low and high are 0-3F or FF. Example: 08-0F,00-07,FF-FF,10-1F,20-27,FF-FF,28-2F,30-3F
gas-comeback-delay <gas-comeback-delay>	At the end of the GAS comeback delay interval, the client may attempt to retrieve the query response using a Comeback Request Action frame. The supported range is 100-2000 milliseconds, and the default value is 500 milliseconds.
grp-frame-block	This option configures the Downstream Group Addressed Forwarding Disabled Mode. If this feature is enabled, it ensures that the AP does not forward downstream group-addressed frames. It is disabled by default, allowing the AP to forward downstream group-addressed frames.
hessid <hessid>	This optional parameter devices an AP's homogenous ESS identifier, which is that device's MAC address in colon-separated hexadecimal format.
hotspot-enable	Enables or disables the hotspot. When this feature is enabled, the Information Elements (IEs) for this hotspot are included in beacons and probe responses from the AP. This setting is disabled by default.
hotspot-osen	Enables or disables the hotspot osen.
hotspot-roam-cons-oi-1	Roaming Consortium entry 1 OI value and length.
hotspot-roam-cons-oi-2	Roaming Consortium entry 2 OI value and length.

Parameter	Description
hotspot-roam-cons-oi-3	Roaming Consortium entry 3 OI value and length.
internet	If you issue the <code>internet</code> parameter, the AP sends an IE indicating that the network allows internet access. By default, a hotspot profile does not advertise network internet access.
no	Negates or removes any configured parameter.
osu-nai	OSU NAI for OSEN.
p2p-cross-connect	Issue this command to advertise support for P2P Cross Connections. This setting is disabled by default.
p2p-dev-mgmt	Issue this command to advertise support for P2P device management. This setting is disabled by default.
pame-bi	This option enables the Pre-Association Message Exchange BSSID Independent (PAME-BI) bit, which is used by an AP to indicate whether the AP indicates that the Advertisement Server can return a query response that is independent of the BSSID used for the GAS Frame exchange.
query-response-length-limit <query-response-length-limit>	GAS enables advertisement services that lets clients query multiple 802.11 networks at once, while also allowing the client to learn more about a network's 802.11 infrastructure before associating. If a client transmits a GAS Query using a GAS Initial Request frame, the responding AP will provide the query response (or information on how to receive the query response) in a GAS Initial Response frame. This parameter sets the maximum length of the GAS query response, in octets. The supported range is 1-255 octets.
radius-cui	Include this parameter to enable the Chargeable-User-Identity RADIUS attribute defined by RFC 4372. Home networks can use this attribute to identify a user for the roaming transactions that take place outside of that home network.
radius-loc-data	Include this parameter to enable the Location Data RADIUS attribute defined by RFC 5580. Enabling this parameter allows the RADIUS server to use location data.
reauth-delay <reauth-delay>	Delay required before STA can re-auth with AP after it is deauthenticated.
release number	Hotspot 2.0 Release Number: <ul style="list-style-type: none"> ■ Release #1 ■ Release #2 ■ Reserved

Parameter	Description
session-info-url <session-info-url>	Specify URL for the Session Information Server.
sub-death-reason-url	Specify URL that explains why STA was not authorized or is no longer authorized.
sub-rem-server-url	Specify URL for the Subscription Remediation Server.
time-advt-cap no-std-ext-timesrc timestamp-offset-utc reserved	<p>This parameter specifies the AP's source of external time, and the current condition of its timing estimator.</p> <ul style="list-style-type: none"> ■ no-std-ext-time-src: The AP using this profile has no standardized external time source. ■ timestamp-offset-utc: The AP has a timestamp offset based on UTC. ■ reserved: This setting is reserved for future use, and should not be used.
time-error	The standard deviation of error in time value estimate, in milliseconds. The default value is 0 milliseconds, and the supported range is 0- 2,147,483,647 milliseconds.
time-zone	<p>The time zone in which the AP is operating, in the format <std><offset>[dst[offset] [,start[/time],end[/time]]]</p> <p>Where the <std> string specifies the abbreviation of the time zone, <dst> is the abbreviation of the timezone in daylight savings time, and the <offset> string specifies the time value you must add to the local time to arrive at UTC.</p> <p>NOTE: For complete details on configuring the timezone format, refer to section 8.3 of IEEE Std 1003.1, 2004 Edition.</p>
venue-group <venue-group>	<p>Specify one of the following venue groups to be advertised in the IEs from APs associated with this hotspot profile. The default setting is unspecified.</p> <ul style="list-style-type: none"> ■ assembly ■ business ■ educational ■ factory-or-industrial ■ institutional ■ mercantile ■ outdoor ■ reserved ■ residential ■ storage ■ unspecified ■ utility-misc ■ vehicular

Parameter	Description
	<p>NOTE: This parameter only defines the venue group advertised in the IEs from hotspot APs. To define the venue group to be included in ANQP responses, use anqp-venue-name-profile <profile-name>.</p>
venue-type <venue-type>	<p>Specify a venue type to be advertised in the IEs from APs associated with this hotspot profile. The complete list of supported venue types is described in Venue Types on page 4176</p> <p>NOTE: This parameter only defines the venue type advertised in the IEs from hotspot APs. To define the venue type to be included in ANQP responses, use anqp-venue-name-profile <profile-name>.</p>

Generic Advertisement Service Queries

An Organization Identifier is a unique identifier assigned to a service provider when it registers with the IEEE registration authority. An AP can include its service provider OI in beacons and probe responses to clients. If a client recognizes an AP's OI, it will attempt to associate to that AP using the security credentials corresponding to that service provider.

If the client does *not* recognize the AP's OI, that client can send a GAS query to the AP to request more information more about the network before associating.

ANQP Information Elements

ANQP IEs are additional data that can be sent from the AP to the client to identify the AP's network and service provider. If a client requests this information via a GAS query, the hotspot AP then sends the ANQP Capability list in the GAS Initial Response frame indicating support for the following IEs:

- **Venue Name:** defined using the [wlan hotspot anqp-venue-name-profile](#) command.
- **Domain Name:** defined using the [wlan hotspot anqp-domain-name-profile](#) command.
- **Network Authentication Type:** defined using the [wlan hotspot anqp-nwk-auth-profile](#) command.
- **Roaming Consortium List:** defined using the [wlan hotspot anqp-roam-cons-profile](#) command.
- **AI Realm:** defined using the [wlan hotspot anqp-nai-realm-profile](#) command.
- **Cellular Network Data:** defined using the [wlan hotspot anqp-3gpp-nwk-profile](#) command.
- **Connection Capability:** defined using the [wlan hotspot h2qp-conn-capability-profile](#) command.
- **Operator Class:** defined using the [wlan hotspot h2qp-op-cl-profile](#) command.
- **Operator Friendly Name:** defined using the [wlan hotspot h2qp-operator-friendly-name-profile](#) command.
- **WAN Metrics:** defined using the [wlan hotspot h2qp-wan-metrics-profile](#).

Roaming Consortium OIs

Organization Identifiers (OIs) are assigned to service providers when they register with the IEEE registration authority. You can specify the OI for the hotspot's service provider in the ANQP Roaming Consortium profile using the [wlan hotspot anqp-roam-cons-profile](#) command. This Hotspot profile also allows you to define and send up to three additional roaming consortium OIs for the service provider's top three roaming partners. To send this additional data to clients, you must specify the number of roaming consortium elements a client can query using the `add1-roam-cons-ois <1-3>` parameter, then define those elements using the following parameters:

- `roam-cons-oi-1` and `roam-cons-len 1`
- `roam-cons-oi-2` and `roam-cons-len 2`
- `roam-cons-oi-3` and `roam-cons-len 3`

The configurable values for each additional OI include the Organization Identifier itself, the OI length, and the venue group and venue type associated with those OIs.

Venue Types

The following list describes the different venue types that may be configured in a hotspot profile:

■ <code>assembly-amphitheatre</code>	■ <code>business-fire-station</code>	■ <code>mercantile-shopping-mall</code>
■ <code>assembly-amusement-park</code>	■ <code>business-police-station</code>	■ <code>outdoor-bus-stop</code>
■ <code>assembly-arena</code>	■ <code>business-post-office</code>	■ <code>outdoor-city-park</code>
■ <code>assembly-bar</code>	■ <code>business-professional-office</code>	■ <code>outdoor-kiosk</code>
■ <code>assembly-coffee-shop</code>	■ <code>business-research-and-development</code>	■ <code>outdoor-muni-mesh-nwk</code>
■ <code>assembly-convention-center</code>	■ <code>educational-primary-school</code>	■ <code>outdoor-rest-area</code>
■ <code>assembly-emer-coord-center</code>	■ <code>educational-secondary-school</code>	■ <code>outdoor-traffic-control</code>
■ <code>assembly-library</code>	■ <code>educational-university</code>	■ <code>residential-boarding-house</code>
■ <code>assembly-museum</code>	■ <code>industrial-factory</code>	■ <code>residential-dormitory</code>
■ <code>assembly-passenger-terminal</code>	■ <code>institutional-alcohol-or-drug-rehab</code>	■ <code>residential-hotel</code>
■ <code>assembly-restaurant</code>	■ <code>institutional-group-home</code>	■ <code>residential-private-residence</code>
■ <code>assembly-stadium</code>	■ <code>institutional-hospital</code>	■ <code>unspecified</code>
■ <code>assembly-theater</code>	■ <code>institutional-prison</code>	■ <code>vehicular-airplane</code>
■ <code>assembly-worship-place</code>	■ <code>institutional-terminal-care</code>	■ <code>vehicular-automobile</code>
■ <code>assembly-zoo</code>	■ <code>mercantile-automotive-service-station</code>	■ <code>vehicular-bus</code>
■ <code>business-attorney</code>	■ <code>mercantile-gas-station</code>	■ <code>vehicular-ferry</code>
■ <code>business-bank</code>	■ <code>mercantile-grocery</code>	■ <code>vehicular-motor-bike</code>
■ <code>business-doctor</code>	■ <code>mercantile-retail</code>	■ <code>vehicular-ship</code>
		■ <code>vehicular-train</code>

Example

The following example configures a hotspot profile with one additional roaming consortium OI for the service provider's top roaming partner:

```
(host) [md] (config) #wlan hotspot hs2-profile profile2
(host) [md] (Hotspot 2.0 Profile "profile2") #venue-group mercantile(host)
[md] (Hotspot 2.0 Profile "profile2") #venue-type mercantile-shopping-mall
(host) [md] (Hotspot 2.0 Profile "profile2") #addtl-roam-cons-ois
(host) [md] (Hotspot 2.0 Profile "profile2") #roam-cons-len 3
(host) [md] (Hotspot 2.0 Profile "profile2") #roam-cons-oil 415B8C
{host) [md] (Hotspot 2.0 Profile "profile2") #hotspot-enable
```

Related Commands

Command	Description
wlan hotspot anqp-3gpp-nwk-profile	This profile defines information for a 3GPP Cellular Network for hotspots that have roaming relationships with cellular operators.
wlan hotspot anqp-domain-name-profile	This command defines the domain name to be sent in an ANQP information element in a GAS query response.
wlan hotspot anqp-ip-addr-avail-profile	This command defines available IP address types to be sent in an ANQP information element in a GAS query response.
wlan hotspot anqp-nai-realm-profile	This command defines a Network Access Identifier realm whose information can be sent as an ANQP information element in a GAS query response
wlan hotspot anqp-nwk-auth-profile	This command configures an ANQP Network Authentication profile to define authentication type being used by the hotspot network.
wlan hotspot anqp-roam-cons-profile	This command configures the Roaming Consortium OI information to be sent in an ANQP information element in a GAS query response
wlan hotspot anqp-venue-name-profile	This command defines venue information be sent in an ANQP information element in a GAS query response.
wlan hotspot h2qp-conn-capability-profile	Defines a H2QP profile that advertises hotspot protocol and port capabilities.

Command	Description
<u>wlan hotspot h2qp-op-cl-profile</u>	Defines a H2QP profile that defines the Operating Class to be sent in the ANQP IE.
<u>wlan hotspot h2qp-operator-friendly-name-profile</u>	Defines a H2QP operator-friendly name profile.
<u>wlan hotspot h2qp-wan-metrics-profile</u>	Creates a H2QP profile that specifies the hotspot WAN status and link metrics.

Description

This command configures a high-throughput SSID profile.

The ht-ssid profile configures the high-throughput SSID. Stations are not allowed to use HT with TKIP stand-alone encryption, although TKIP can be provided in mixed-mode BSSIDs that support HT. HT is disabled on a BSSID if the encryption mode is stand-alone TKIP or WEP.

You can also use this profile to configure explicit transmit beamforming for 130 Series access points. When this feature is enabled, the AP coordinates the signals sent from each antenna so the signals focus on the receiver, improving radio range and performance. The 130 Series AP can advertise transmit beamforming capabilities in beacon, probe response and association responses in the HT capabilities IE, then use the compressed or noncompressed beamforming report from clients to form a steering matrix. The AP ensures that the steering matrix stays current by updating and recalibrating the steering matrix at regular intervals.

By default, 130 Series access points support both compressed and non-compressed steering information from clients. If you have many clients that can send only non-compressed steering

reports, best practices are to retain the default settings, allowing the AP to support both types of steering reports. If all (or nearly all) of the AP's clients are capable of sending compressed steering reports, best practices are to disable non-compressed steering in the AP's HT SSID profile.

De-aggregation of MSDUs is supported with a maximum frame transmission size of 4 KBs; however, this feature is always enabled and is not configurable. Aggregation is not currently supported.

Parameter	Description
<profile-name>	Name of this instance of the profile. The name must be 1-63 characters. default
40MHz-enable	Enables or disables the use of this high-throughput SSID in 40 MHz mode. enabled
80MHz-enable	Enables or disables the use of 80 MHz channels on VHT APs. enabled
ba-amsdu-enable	Enables or disables Receive AMSDU in Block ACK (BA) negotiation. If disabled, AP denies clients from sending AMSDU using BA agreement. enabled
clone	Name of an existing high-throughput SSID profile from which parameter values are copied.
high-throughput-enable	Enables or disables high-throughput SSID to allow high-throughput (802.11n) stations to associate. Enabling high-throughput in an ht-ssid-profile enables WMM base features for the associated SSID. enabled
ldpc	If enabled, the AP will advertise LDPC support. LDPC improves data transmission over radio channels with high levels of background noise. enabled
legacy-stations	Controls whether or not legacy (non-HT) stations are allowed to associate with this SSID. By default, legacy stations are allowed to associate. This setting has no effect on a BSS in which HT support is not available. enabled
max-rx-a-mpdu-size	Controls the maximum size, in bytes, of an A-MPDU that can be received on this high-throughput SSID.

Parameter	Description
	8191, 16383, 32767, 65535 65535
8191	Maximum size of 8191 bytes.
16383	Maximum size of 16383 bytes.
32767	Maximum size of 32767 bytes.
65535	Maximum size of 65535 bytes.
max-tx-a-mpdu-size	Controls the maximum size, in bytes, of an A-MPDU that can be sent on this high-throughput SSID. 1576-65535 65535
max-tx-a-masdu-count-be	Sets the maximum number of MSDUs in a TX A-MSDU on best effort AC. NOTE: In tunnel and decrypt-tunnel forwarding mode, TX A-MSDU is disabled if the value is set to 0. If the value is set to non-zero, TX A-MSDU is enabled and set to this value. 0-15 2
max-tx-a-masdu-count-bk	Sets the maximum number of MSDUs in a TX A-MSDU on background AC. NOTE: TX A-MSDU is disabled if the value is set to 0. In decrypt-tunnel forwarding mode, TX A-MSDU on background AC is disabled and assigning any value has no effect. 0-15 2
max-tx-a-masdu-count-vi	Sets the maximum number of MSDUs in a TX A-MSDU on video AC. NOTE: TX A-MSDU is disabled if the value is set to 0. In decrypt-tunnel forwarding mode, TX A-MSDU on video AC is disabled and assigning any value has no effect. 0-15 2
max-tx-a-masdu-count-vo	Sets the maximum number of MSDUs in a TX A-MSDU on voice AC.

Parameter	Description
	<p>NOTE: TX A-MSDU is disabled if the value is set to 0. In decrypt-tunnel forwarding mode, TX A-MSDU on voice AC is disabled and assigning any value has no effect.</p> <p>0-15 0</p>
max-vht-mpdu-size	<p>Maximum size of a VHT MPDU. 3895, 7991, or 11454 bytes 11454 bytes</p>
min-mpdu-start-spacing	<p>Minimum time between the start of adjacent MDPUs within an aggregate MPDU in microseconds. 0, .25, .5, 1, 2,4, 8,16 0</p>
0	No restriction on MPDU start spacing.
.25	Minimum time of .25 μ sec.
.5	Minimum time of .5 μ sec.
1	Minimum time of 1 μ sec.
2	Minimum time of 2 μ sec.
4	Minimum time of 4 μ sec.
8	Minimum time of 8 μ sec.
16	Minimum time of 16 μ sec.
mpdu-agg	<p>Enables or disables MAC protocol data unit (MPDU) aggregation. High-throughput APs are able to send aggregated MDPUs, which allow an AP to receive a single block acknowledgment instead of multiple ACK signals. This option, which is enabled by default, reduces network traffic overhead by effectively eliminating the need to initiate a new transfer for every MPDU. enabled</p>
no	Negates any configured parameter.
rx-ampdu	Enables or disables Receive AMPDU in Block ACK (BA) negotiation.

Parameter	Description
short-guard-intvl-20MHz	<p>Enables or disables use of short guard interval (400 ns) in 20 MHz mode.</p> <p>A guard interval is a period of time between transmissions that allows reflections from the previous data transmission to settle before an AP transmits data again. An AP identifies any signal content received inside this interval as unwanted inter-symbol interference, and rejects that data. The 802.11n standard specifies two guard intervals: 400 ns (short) and 800 ns (long). Enabling a short guard interval can decrease network overhead by reducing unnecessary idle time on each AP. Some outdoor deployments, may, however require a longer guard interval. If the short guard interval does not allow enough time for reflections to settle in your mesh deployment, inter-symbol interference values may increase and degrade throughput.</p> <p>enabled</p>
short-guard-intvl-40MHz	<p>Enables or disables use of short guard interval (400 ns) in 40 MHz mode of operation.</p> <p>enabled</p>
short-guard-intvl-80MHz	<p>Enables or disables use of short guard interval (400 ns) in 80 MHz mode of operation.</p> <p>enabled</p>
stbc-rx-streams	<p>Control the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the AP-105, 130 Series, and 170 Series only. The configured value will be adjusted based on AP capabilities.)</p> <p>NOTE: If transmit beamforming is enabled, STBC will be disabled for beamformed frames.</p> <p>0-1 1</p>
stbc-tx-streams	<p>Control the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on AP-105, 130 Series, and 170 Series only. The configured value will be adjusted based on AP capabilities.)</p> <p>NOTE: If transmit beamforming is enabled, STBC will be disabled for beamformed frames.</p> <p>0-1 1</p>

Parameter	Description
supported-mcs-set	<p>A list of MCS values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20 MHz vs. 40 MHz vs. 80 MHz) and the number of spatial streams used by the mesh node.</p> <p>To specify a smaller range of values, enter a hyphen between the lower and upper values. To specify a series of different values, separate each value with a comma.</p> <p>Examples: 2-10 1,3,6,9,12 MCS value of 16-23 are supported on 130 Series/RAP-155/11ac APs only. MCS value of 24-31 are supported on 320 Series APs only. 0-31</p>
temporal-diversity	<p>Enable or disable temporal diversity. When this setting is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries.</p> <p>disabled</p>
very-high-throughput-enable	<p>Enable or disable support for VHT (802.11ac) on the SSID.</p> <p>enabled</p>
vht-mu-txbf-enable	<p>Enable or disable VHT Multi-User Transmit Beamforming. If this parameter is disabled, all other Multi-User Transmit Beamforming configuration parameters have no effect.</p> <p>NOTE: This parameter is applicable for 320 Series APs only.</p> <p>enabled</p>
vht-supported-mcs-map	<p>Comma separated list of maximum supported MCS for spatial streams 1 through 4. Valid values for maximum MCS are 7, 8, 9, and '-' (if spatial stream is not supported). Maximum MCS of a spatial stream cannot be higher than the previous streams. If an MCS is not valid for a particular combination of bandwidth and number of spatial streams, it will not be used for Tx and Rx.</p> <p>7, 8, 9, or - 9,9,9,9</p>
vht-txbf-explicit-enable	<p>Enable or disable VHT Explicit Transmit Beamforming for the 802.11ac-capable APs. When this feature is enabled, the AP requests information about the MIMO channel and uses that information to transmit data over multiple transmit streams using a calculated steering matrix. The result is higher throughput due to improved signal at the beamformee (the receiving client). If this parameter is disabled, all other transmit beamforming settings will not take effect.</p>

Parameter	Description
	enabled
vht-txbf-sounding-interval	<p>Time interval in milliseconds between channel information updates between the AP and the beamformee client.</p> <p>NOTE: This is applicable for 802.11ac-capable APs only.</p> <p>1-1000 msec 25 msec</p>

Example

The following example configures the maximum size of a received aggregate MPDU to be 8191 bytes for the high-throughput SSID named htcorpnet:

```
(host) [md] (config) #wlan ht-ssid-profile htcorpnet
(host) [md] (High-throughput SSID profile "htcorpnet") #max-rx-a-mpdu-size
8191
```

Command History

wlan mu-edca-parameters-profile

```
wlan mu-edca-parameters-profile <profile-name>
  clone
  mu-background
  mu-best-effort
  mu-video
  mu-voice
  no
```

Description

This command configures an MU EDCA profile for APs or for clients (stations).

MU EDCA profiles are specific either to APs or clients. You apply an MU EDCA profile to a specific SSID profile. Use this command only under the guidance of your Aruba technical support representative.

Parameter	Description
<profile-name>	Name of the profile.
clone <source>	Copy data from another MU EDCA parameters profile.
no	Remove or negate a parameter.
mu-background	EDCA parameters for background queue.
mu-best-effort	EDCA parameters for best-effort queue.
mu-video	EDCA parameters for video queue.
mu-voice	EDCA parameters for voice queue.
aifsn <1-15>	Arbitrary inter-frame space number
ecw-max <0-15>	Maximum contention window (exponent)
ecw-min <0-15>	Minimum contention window (exponent)
timer <0-255>	MU EDCA Timer.

Example

The following example configures an EDCA profile for APs:

```
(host) [/md] (config) #wlan mu-edca-parameters-profile default
(host) [/md] (EDCA Parameters profile (AP) "default") #best-effort ecw-min
15 ecw-max 15 aifsn 15 1
```

wlan rrm-ie-profile

```
wlan rrm-ie-profile <profile-name>
  bss-aac-ie
  clone
  country-ie
  enabled-capabilities-ie
  no
  pwr-constraint-ie
  qbss-load-ie
  quiet-ie
  tpc-report-ie
```

Description

This command configures a radio resource management (RRM) IE profile to define the information elements advertised by an AP with 802.11k support enabled. ArubaOS supports RRM IEs for APs with 802.11k support enabled. All IEs are sent by default.

Parameter	Description
bss-aac-ie	The AP will advertise in beacon and probe responses the BSS Available Admission Capacity IE, which contains information about the admission capabilities for each User Priority or AC.
clone	Copy the settings of an existing RRM IE profile.
country-ie	The AP will advertise in beacon and probe responses the device's regulatory domain.
enabled-capabilities-ie	The AP will advertise in beacon and probe responses support for radio measurements in a device.
no ...	Disables the transmission of an IE in this profile.
pwr-constraint-ie	The AP will advertise in beacon and probe responses the regulatory maximum transmit power for that current channel.
qbss-load-ie	The AP will advertise in beacon and probe responses the QBSS Load IE, which contains information on the current station count, channel utilization and available admission capacity levels in the QBSS.
quiet-ie	The AP will advertise in beacon and probe responses the Quiet IE, which is used to silence the channel for measurement purposes. When an AP uses a quiet IE to schedule a quiet interval, stations may not transmit on that channel during the quiet interval.
tpc-report-ie	The AP will advertise in beacon and probe responses information about its TCP.

Example

The following example prevents the AP from advertising the country IE:

```
(host) [md] (config) #wlan rrm-ie-profile default
(host) [md] (RRM IE Profile "default") #no country-ie
```

Command History

Release	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

wlan sae-profile

```
wlan sae-profile
  anti-clogging-token-threshold <anti-clogging-token-threshold>
  auth-frame-retransmit-interval <auth-frame-retransmit-interval>
  giveup-threshold <giveup-threshold>
no
```

Description

This command configures an SSID profile.

The SSID profile configures the SSID. Default WMM mappings exist for all SSIDs. After you customize an WMM mapping and apply it to the SSID, the Mobility Conductor overwrites the default mapping values and uses the user-configured values.

	Description
anti-clogging-token-threshold <anti-clogging-token-threshold>	Simultaneous SAE negotiations above which anti-clogging-token is required.
auth-frame-retransmit-interval	Configure interval between retransmits for SAE Auth frame.

	Description
<auth-frame-retransmit-interval>	20-1000 milliseconds
giveup-threshold <giveup-threshold>	Number of SAE Auth frames transmissions before giving up.
no	Negates any configured parameter.

Example

The following example configures an SSID for WPA2 AES authentication:

```
(host) [md] (config) #wlan sae-profile
(host) [md] (WPA3 SAE Configuration) #
```

Description

This command configures an SSID profile.

The SSID profile configures the SSID. Default WMM mappings exist for all SSIDs. After you customize an WMM mapping and apply it to the SSID, the Mobility Conductor overwrites the default mapping values and uses the user-configured values.

	Description
<profile-name>	Name of this instance of the profile. The name must be 1-63 characters. default
a-basic-rates	List of supported 802.11a rates, in Mbps, that are advertised in beacon frames and probe responses. 6, 9, 12, 18, 24, 36, 48, 54 Mbps 6, 12, 24 Mbps
a-beacon-rate	Sets the beacon rate for 802.11a (use for DAS only). Using this parameter in normal operation may cause connectivity problems. default, 6, 9, 12, 18,24,36,48,54 Mbps minimum valid rate
a-tx-rates	Set of 802.11a rates at which the AP is allowed to send data. The actual transmit rate depends on what the client is able to handle, based on information sent at the time of association and on the current error or loss rate of the client. 6, 9, 12, 18, 24, 36, 48, 54 Mbps

	Description
advertise-ap-name	<p>If enabled, APs that are part of this VAP will broadcast AP names in beacon and probe response frames as a part of the vendor-specific Information Element.</p> <p>200 Series, 203H Series, 203R Series, 205H Series, 207 Series, 210 Series, 220 Series, AP-228, and 270 Series do not broadcast AP names in probe response frames.</p> <p>Disabled</p>
advertise-location	<p>If enabled, APs that are part of this VAP will broadcast their GPS coordinates in the beacons and probe response frames as part of a vendor-specific Information Element.</p> <p>Disabled</p>
ageout	<p>Time, in seconds, that a client is allowed to remain idle before being aged out.</p> <p>1000 seconds</p>
auth-req-thresh	<p>The SNR threshold below which incoming authentication requests are ignored. Use this parameter instead of the local probe request threshold parameter to filter out low SNR authentication request.</p> <p>NOTE: Use this parameter with caution. Consult technical support before configuring this parameter.</p> <p>0-100 dB 0 dB</p>
battery-boost	<p>Converts multicast traffic to unicast before delivery to the client, thus allowing you to set a longer DTIM interval. The longer interval keeps associated wireless clients from activating their radios for multicast indication and delivery, leaving them in power-save mode longer and thus lengthening battery life.</p> <p>NOTE: This parameter requires the PEFNG license. This parameter should not be enabled if you plan on using the Push-To-Talk feature for Polycom SpectraLink devices.</p> <p>Disabled</p>
cdc-enable	<p>Advertizes the Cellular Data Capability (CDC) attribute of an MBO.</p>

	Description
	NOTE: CDC can only be enabled when MBO is enabled.
clone	Name of an existing SSID profile from which parameter values are copied.
deny-bcast	When a client sends a broadcast probe request frame to search for all available SSIDs, this option controls whether or not the system responds for this SSID. When enabled, no response is sent and clients have to know the SSID in order to associate to the SSID. When disabled, a probe response frame is sent for this SSID. Disabled
disable-probe-retry	Enables or disables battery MAC level retries for probe response frames. By default this parameter is enabled, which mean that MAC level retries for probe response frames is disabled. NOTE: This parameter is not supported for 200 Series, 210 Series, 220 Series, 270 Series access points. NOTE: Enabled
dot11r-profile	Associates the dot11r-profile with the SSID profile.
dtim-period	Specifies the interval, in beacon periods, between the sending of DTIMs in the beacon. This is the maximum number of beacon cycles before unacknowledged network broadcasts are flushed. When using wireless clients that employ power management features to sleep, the client must revive at least once during the DTIM period to receive broadcasts. 1
eapol-rate-opt	Uses a more conservative rate for more reliable delivery of EAPOL frames. Enabled
edca-parameters-profile	Name of the EDCA profile that applies to this SSID.

	Description
	NOTE: This parameter requires the PEFNG license. Configure this parameter only under the guidance of your Aruba representative.
ap station	Assigns the specified EDCA profile to AP or station (client).
enforce-user-vlan	Enforces data traffic only in user's assigned vlan (Open stations only).
ssid	Name that uniquely identifies a wireless network. The ESSID can be up to 32 characters. If the ESSID includes spaces, you must enclose it in quotation marks.
g-basic-rates	List of supported 802.11b/g rates that are advertised in beacon frames and probe responses. 1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54 Mbps 1, 2 Mbps
g-beacon-rate	Sets the beacon rate for 802.11g (use for DAS only). Using this parameter in normal operation may cause connectivity problems. default, 1,2,5, 6 9, 11, 12, 18, 24, 36, 48, 54 Mbps minimum valid rate
g-tx-rates	Set of 802.11b/g rates at which the AP is allowed to send data. The actual transmit rate depends on what the client is able to handle, based on information sent at the time of association and on the current error or loss rate of the client. 1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54 Mbps
he-ssid-profile	Name of high-efficiency SSID profile to use for configuring high-efficiency support. default
hide-ssid	Enables or disables hiding of the SSID name in beacon frames. Note that hiding the SSID does very little to increase security. Disabled
ht-ssid-profile	Name of high-throughput SSID profile to use for configuring high-throughput support. See wlan ht-ssid-profile on page 4179 .

	Description
	default
local-probe-req-thresh	APs will not respond to client probe requests if the SNR value in the probe request is less than the specified threshold value. 0-100 dB 0 dB
max-clients	Maximum number of wireless clients for the AP. This parameter is limited to 1024 clients per radio. Default value for this parameter is the maximum number of clients supported by the AP.
max-retries	Maximum number of retries allowed for the AP to send a frame. 0-15 4
max-tx-fail	The AP assumes the client has left and should be deauthorized when the AP detects this number of consecutive frames were not delivered because the max-retries threshold was exceeded. 0 -2,147,483,647 0
mbo-enable	Enables the Agile Multiband Operations (MBO). Enables the mfp-capable, 802.11k and 802.11u-interworking implicitly on the AP.
mcast-rate-opt	Choose the optimal rate for broadcast/multicast frames.
mcast-rate-opt	Enables or disables scanning of all active stations currently associated to an AP to select the lowest transmission rate for broadcast and multicast frames. This option only applies to broadcast and multicast data frames; 802.11 management frames are transmitted at the lowest configured rate. NOTE: Do not enable this parameter unless instructed to do so by your Aruba technical support representative. Disabled

	Description																																																																				
mfp-capable	<p>When enabled, the SSID supports management frame protection (MFP) capable clients and traditional clients.</p> <p>Disabled</p>																																																																				
mfp-required	<p>When enabled, the SSID only supports MFP capable clients.</p> <p>Disabled</p>																																																																				
multicast-rate	<p>When configured, the Mobility Conductor chooses the rate for video multicast frames. You can configure MCS rates as well. MCS is an important setting because it provides for potentially greater throughput.</p> <p>NOTE: The following information displays the MCS rate if the <code>short-guard-intvl-20MHz</code> parameter in ht-ssid-profile is either enabled or disabled:</p> <table border="1" data-bbox="878 894 1370 1501"> <thead> <tr> <th>MCS SGI</th> <th>Streams</th> <th>20 MHz</th> <th>20 MHz</th> </tr> </thead> <tbody> <tr><td>0</td><td>1</td><td>6.5</td><td>7.2</td></tr> <tr><td>1</td><td>1</td><td>13.0</td><td>14.4</td></tr> <tr><td>2</td><td>1</td><td>19.5</td><td>21.7</td></tr> <tr><td>3</td><td>1</td><td>26.0</td><td>28.9</td></tr> <tr><td>4</td><td>1</td><td>39.0</td><td>43.3</td></tr> <tr><td>5</td><td>1</td><td>52.0</td><td>57.8</td></tr> <tr><td>6</td><td>1</td><td>58.5</td><td>65.0</td></tr> <tr><td>7</td><td>1</td><td>65.0</td><td>72.2</td></tr> <tr><td>8</td><td>2</td><td>13.0</td><td>14.4</td></tr> <tr><td>9</td><td>2</td><td>26.0</td><td>28.9</td></tr> <tr><td>10</td><td>2</td><td>39.0</td><td>43.3</td></tr> <tr><td>11</td><td>2</td><td>52.0</td><td>57.8</td></tr> <tr><td>12</td><td>2</td><td>78.0</td><td>86.7</td></tr> <tr><td>13</td><td>2</td><td>104.0</td><td>115.6</td></tr> <tr><td>14</td><td>2</td><td>117.0</td><td>130.0</td></tr> <tr><td>15</td><td>2</td><td>130.0</td><td>144.4</td></tr> </tbody> </table> <p>NOTE: The MCS rates for video multicast are supported in all 802.11n -capable APs.</p> <p>default, 6, 9, 12, 18, 24, 36, 48, 54 Mbps mcs0-mcs15 default</p>	MCS SGI	Streams	20 MHz	20 MHz	0	1	6.5	7.2	1	1	13.0	14.4	2	1	19.5	21.7	3	1	26.0	28.9	4	1	39.0	43.3	5	1	52.0	57.8	6	1	58.5	65.0	7	1	65.0	72.2	8	2	13.0	14.4	9	2	26.0	28.9	10	2	39.0	43.3	11	2	52.0	57.8	12	2	78.0	86.7	13	2	104.0	115.6	14	2	117.0	130.0	15	2	130.0	144.4

	Description
multiple-tx-replay-counters	Enables Multiple Tx Replay Counters.
no	Negates any configured parameter.
okc	OKC is a similar technique, not defined by 802.11i, available for authentication between multiple APs in a network where those APs are under common administrative control. An Aruba deployment with multiple APs under the control of a single controller is one such example. Using OKC, a station roaming to any AP in the network will not have to complete a full authentication exchange, but will instead just perform the 4-way handshake to establish transient encryption keys. Enabled
opmode	The layer-2 authentication and encryption to be used on this ESSID to protect access and ensure the privacy of the data transmitted to and from the network. opensystem
bSec-128	WPA2 with AES GCM-128 encryption and dynamic keys using 802.1X
bSec-256	WPA2 with AES GCM-256 encryption and dynamic keys using 802.1X
dynamic-wep	WEP with dynamic keys.
enhanced-open	Improved data encryption in open Wi-Fi networks and protects data from sniffing. Enhanced open replaces open system as the default opmode.
mpsk-aes	AES encryption using a pre-shared key.
opensystem	No authentication and encryption.
static-wep	WEP with static keys.
wpa-aes	WPA with AES encryption and dynamic keys using 802.1X.
wpa-psk-aes	WPA with AES encryption using a preshared key.
wpa-psk-tkip	WPA with TKIP encryption using a preshared key.
wpa-tkip	WPA with TKIP encryption and dynamic keys using 802.1X.

	Description
wpa2-aes	WPA2 with AES encryption and dynamic keys using 802.1X.
wpa2-psk-aes	WPA2 with AES encryption using a preshared key.
wpa2-psk-tkip	WPA2 with TKIP encryption using a preshared key.
wpa2-tkip	WPA2 with TKIP encryption and dynamic keys using 802.1X.
wpa3-aes-ccm-128	WPA3 with AES CCM-128 encryption and dynamic keys using 802.1X.
wpa3-aes-gcm-256	WPA3 with AES GCM-256 encryption.
wpa3-cnsa	WPA3 with AES GCM-256 encryption using CNSA (192 bit).
wpa3-sae-aes	WPA3 with AES encryption using Simultaneous Authentication of Equals.
xSec	Encryption and tunneling of Layer-2 traffic between the managed device and wired or wireless clients, or between managed devices. To use xSec encryption, you must use a RADIUS authentication server. For clients, you must install the Funk Odyssey client software. Requires installation of the xSec license. For xSec between managed devices, you must install an xSec license in each managed device.
opmode-transition	Enables backward compatibility for enhanced open or WPA3-SAE-AES opmodes. Enabled
qbss-load-enable	Enables the AP to advertise the QBSS load element. The element includes the following parameters that provide information on the traffic situation: <ul style="list-style-type: none"> ▪ <code>Station count</code>: The total number of stations associated to the QBSS. ▪ <code>Channel utilization</code>: The percentage of time (normalized to 255) the channel is sensed to be busy. The access point uses either the physical or the virtual carrier sense mechanism to sense a busy channel. ▪ <code>Available admission capacity</code>: The remaining amount of medium time

	Description
	<p>(measured as number of 32us/s) available for a station via explicit admission control. The QAP uses these parameters to decide whether to accept an admission control request. A wireless station uses these parameters to choose the appropriate access points.</p> <p>NOTE: Ensure that wmm is enabled for legacy APs to advertise the QBSS load element. For 802.11n APs, ensure that either wmm or high throughput is enabled.</p> <p>Disabled</p>
refresh-direction	The refresh direction of WLAN SSID profile.
<bidirectional>	Bidirectional data frames that are used for station refresh.
<rx-only>	<p>Received data frames that are used for station refresh.</p> <p>NOTE: The receive-only mode does not use null frames for station refresh.</p>
<tx-only>	Transmitted data frames that are used for station refresh.
rts-threshold	Wireless clients transmitting frames larger than this threshold must issue RTS and wait for the AP to respond with CTS. This helps prevent mid-air collisions for wireless clients that are not within wireless peer range and cannot detect when other wireless clients are transmitting. 2333 bytes
send-transition-disable	Send Transition-Disable KDE to WPA3 clients.
short-preamble	<p>Enables or disables short preamble for 802.11b/g radios. Network performance may be higher when short preamble is enabled. In mixed radio environments, some 802.11b wireless client stations may experience difficulty associating with the AP using short preamble. To use only long preamble, disable short preamble. Legacy client devices that use only long preamble generally can be updated to support short preamble.</p> <p>Enabled</p>
strict-svp	Enable Strict Spectralink Voice Protocol (SVP)

	Description
	Disabled
traffic-steering	If enabled, traffic steering is done for EAP-SIM/EAP-AKA clients that are connected to this SSID.
wepkey1 - wepkey4	Static WEP key associated with the key index. Can be 10 or 26 hex characters in length.
wepkey	Key index that specifies which static WEP key is to be used. 1, 2, 3, 4 1
wmm	Enables or disables WMM, also known as IEEE 802.11e Enhanced Distribution Coordination Function. WMM provides prioritization of specific traffic relative to other traffic in the network. Disabled
wmm-be-dscp	DSCP value used to map WMM best-effort traffic. 0-63
wmm-bk-dscp	DSCP used to map WMM background traffic. 0-63
wmm-dscp-mapping	Enables or disables WMM map to GRE DSCP in D-Tunnel upstream direction.
wmm-eap-ac {background best-effort default video voice}	Override the WMM Access Class (AC) of EAP traffic.
wmm-ts-min-inact-int	Specifies the minimum inactivity time-out threshold of WMM traffic. This setting is useful in environments where low inactivity interval timeouts are advertised, which may cause unwanted timeouts. 0-3,600,000 milliseconds 0 milliseconds
wmm-uapsd	Enable WMM UAPSD powersave. Enabled
wmm-vi-dscp	DSCP used to map WMM video traffic. 0-63

	Description
wmm-vo-dscp	DSCP used to map WMM voice traffic. 0-63
wpa-hexkey	WPA PSK.
wpa-passphrase	WPA passphrase with which to generate a PSK.

Suite-B Cryptography

The `opmode` parameters for Suite-B encryption, `wpa2-aes-gcm-128` and `wpa2-aes-gcm-256`, require the ACR license. All 7000 Series and 7200 Series support Suite-B encryption.

Multicast Rate Optimization

The Multicast Rate Optimization feature dynamically selects the rate for sending broadcast/multicast frames on any BSS. This feature determines the optimal rate for sending broadcast and multicast frames based on the lowest of the unicast rates across all associated clients.

When the Multicast Rate Optimization option ([mcast-rate-opt](#)) is enabled, the Mobility Conductor scans the list of all associated stations in that BSS and finds the lowest transmission rate as indicated by the rate adaptation state for each station. If there are no associated stations in the BSS, it selects the lowest configured rate as the transmission rate for broadcast and multicast frames.

This feature is disabled by default. Multicast Rate Optimization applies to broadcast and multicast frames only. 802.11 management frames are not affected by this feature and will be transmitted at the lowest configured rate.

The Multicast Rate Optimization feature should only be enabled on a BSS where all associated stations are sending or receiving unicast data. If there is no unicast data to or from a particular station, then the rate adaptation state may not accurately reflect the current sustainable transmission rate for that station. This could result in a higher packet error rate for broadcast or multicast packets at that station.

Example

The following example configures an SSID for WPA2 AES authentication:

```
(host) [md] (config) #wlan ssid-profile corpnet
(host) [md] (SSID Profile "corpnet") #essid Corpnet
(host) [md] (SSID Profile "corpnet") #opmode wpa2-aes
```

Command History

Release	Description
ArubaOS 8.7.0.0	The <code>advertise-ap-name</code> parameter was modified to include AP names in probe response frames.
ArubaOS 8.6.0.0	The following parameters were added: <ul style="list-style-type: none"> ▪ <code>cdc-enable</code> ▪ <code>mbo-enable</code>
ArubaOS 8.5.0.0	The <code>refresh-direction</code> parameter was added. The <code>wpa3-aes-gcm-256</code> sub-parameter to the <code>opmode</code> parameter was added.
ArubaOS 8.4.0.0	The following sub-parameters to the <code>opmode</code> parameter and the <code>opmode-transition</code> parameter were added: <ul style="list-style-type: none"> ▪ <code>enhanced-open</code> ▪ <code>mpsk-aes</code> ▪ <code>opensystem</code> ▪ <code>wpa3-aes-ccm-128</code> ▪ <code>wpa3-cnsa</code> ▪ <code>wpa-sae-aes</code>.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms, except for the noted <code>opmode</code> parameters.	Base operating system, except for the noted parameters.	Config mode on Mobility Conductor.

wlan traffic-management-profile

```
wlan traffic-management-profile <profile-name>
  bw-alloc virtual-ap <virtual-ap> share <percent>
  clone <profile-name>
  no ...
  report-interval <minutes>
  shaping-policy default-access|fair-access|preferred-access
```

Description

This command configures a traffic management profile.

The traffic management profile allows you to allocate bandwidth to SSIDs. When you enable the band-steering feature, an AP keeps track of all BSSIDs active on a radio, all clients connected to the BSSID, and 802.11a/g, 802.11b, or 802.11n capabilities of each client. Every sampling period, airtime is allocated to each client, giving it opportunity to get and receive traffic. The specific amount of airtime given to an individual client is determined by;

- Client capabilities (802.11a/g, 802.11b or 802.11n)
- Amount of time the client spent receiving data during the last sampling period
- Number of active clients in the last sampling period
- Activity of the current client in the last sampling period

The `bw-alloc` parameter of a traffic management profile allows you to set a minimum bandwidth to be allocated to a virtual AP profile when there is congestion on the wireless network. You must set traffic shaping to fair-access to use this bandwidth allocation value for an individual virtual AP.

Parameter	Description	Range	Default
<profile-name>	Name of this profile. 1-63 characters. default	—	default
bw-alloc	Minimum bandwidth, as a percentage of available bandwidth, allocated to a Virtual AP when there is congestion on the wireless network. An virtual AP can use all available bandwidth if no other virtual APs are active.		
virtual-ap <virtual-ap>	Name of the virtual AP to which you will allocate a share of bandwidth.	—	—

Parameter	Description	Range	Default
share <percent>	Percentage of available bandwidth allocated to this virtual AP. 0-100	0-100	—
clone <profile-name>	Name of an existing traffic management profile from which parameter values are copied.	—	—
no	Negates any configured parameter.	—	—
report-interval <minutes>	Number of minutes between bandwidth usage reports. 1 - 999999 minutes 5 minutes	1 - 999999 minutes	5 minutes
shaping-policy	Defines the Station Shaping Policy This feature has the following three options: <ul style="list-style-type: none"> ■ default-access: Traffic shaping is disabled, and client performance is dependent on MAC contention resolution. This is the default traffic shaping setting. ■ fair-access: Each client gets the same airtime, regardless of client capability and capacity. This option is useful in environments like a training facility or exam hall, where a mix of 802.11a/g, 802.11g and 802.11n clients need equal to network resources, regardless of their capabilities. The bw-alloc parameter of a traffic management profile allows you to set a minimum bandwidth to be allocated to a virtual AP profile when there is congestion on the wireless network. You must set traffic shaping to fair-access to use this bandwidth allocation value for an individual virtual AP. ■ preferred-access: High- 	default-access fair-access preferred-access	default-access

Parameter	Description	Range	Default
	<p>throughput (802.11n) clients do not get penalized because of slower 802.11a/g or 802.11b transmissions that take more air time due to lower rates. Similarly, faster 802.11a/g clients get more access than 802.11b clients.</p> <p>default-access, fair-access, preferred-access</p> <p>default-access</p>		

Example

The following example configures a traffic management profile that allocates bandwidth to the corpnet virtual AP:

```
(host) [md] (config) #wlan traffic-management-profile best
(host) [md] (Traffic management profile "best") #bw-alloc virtual-ap corpnet
share 75
```

wlan tsm-req-profile

```
wlan tsm-req-profile <profile-name>  
  bin0-range <bin0-range>  
  clone  
  dur-mandatory  
  measure-duration <measure-duration>  
  no  
  num-repeats <num-repeats>  
  random-interval <random-interval>  
  request-mode {normal | triggered}  
  traffic-id <traffic-id>
```

Description

This command configures a TSM Report Request Profile.

The tsm-req-profile is a part of the 802.11K profile. It is used to configure the parameters for the Transmit Stream or Category Measurement frames. It takes effect only when the 802.11K feature is enabled.

Parameter	Description
<profile-name>	Name of this profile. The name must be 1-63 characters. default
bin0-range <bin0-range>	This value is used to set the 'Bin 0 Range' field in the Transmit Stream or Category Measurement Request frame. Bin 0 Range indicates the delay range of the first bin (Bin 0) of the Transmit Delay Histogram, expressed in units of TUs. 0- 255 6
clone <source>	Creates a copy of the Transmit Stream Measurement Request Report Request Profile. <source> is the name of an existing TSM Profile from which parameter values are copied.
dur-mandatory	This parameter is used to set the "Duration Mandatory" bit of the Measurement Request Mode field of the Transmit Stream or Category Measurement Request frame. Enabled

Parameter	Description
<code>measure-duration <measure-duration></code>	<p>This parameter is used to set the Measurement Duration field in the Transmit Stream or Category Measurement Request frame. The Measurement Duration is set to the duration of the requested measurement. It is expressed in units of TUs. When the request mode for the Transmit Stream or Category Measurement Request frame is set to triggered, the Measurement Duration field should be set to 0.</p> <p>0- 65535 9776</p>
<code>no</code>	<p>Negates any configured parameter</p>
<code>num-repeats <num-repeats></code>	<p>This parameter is used to set the Number of Repetitions field in the Transmit Stream or Category Measurement Request frame. The Number of Repetitions field contains the requested number of repetitions for all the Measurement Request elements in this frame. A value of zero in the Number of Repetitions field indicates Measurement Request elements are executed once without repetition. A value of 65535 in the Number of Repetitions field indicates Measurement Request elements are repeated until the measurement is canceled or superseded.</p> <p>0-65535 65535</p>
<code>random-interval <random-interval></code>	<p>This parameter is used to set the Randomization Interval field in the Transmit Stream or Category Measurement Request frame. The Randomization Interval is used to specify the desired maximum random delay in the measurement start time. It is expressed in units of TUs (Time Units). When the request mode for the Transmit Stream or Category Measurement Request frame is set to "triggered", the Randomization Interval is not used and is set to 0. A Randomization Interval of 0 in a measurement request indicates that no random delay is to be used.</p> <p>0-65535 0</p>
<code>request-mode {normal triggered}</code>	<p>This parameter is used to determine the request mode for the Transmit Stream or Category Measurement Request frame.</p> <p>normal, triggered normal</p>

Parameter	Description
traffic-id <traffic-id>	<p>The parameter is used to set the Traffic Identifier field in the Transmit Stream or Category Measurement Request frame. The Traffic Identifier field contains the TID subfield. The TID subfield indicates the TC or TS for which traffic is to be measured.</p> <p>0-255</p> <p>96</p>

Example

The following example configures a TSM Report Request Profile:

```
(host) [md] (config) #wlan tsm-req-profile default
(host) [md] (TSM Report Request Profile "default") #bin0-range 1
(host) [md] (TSM Report Request Profile "default") #dur-mandatory
(host) [md] (TSM Report Request Profile "default") #measure-duration 25
(host) [md] (TSM Report Request Profile "default") #num-repeats 0
(host) [md] (TSM Report Request Profile "default") #random-interval 0
(host) [md] (TSM Report Request Profile "default") #request-mode normal
(host) [md] (TSM Report Request Profile "default") #traffic-id 96
```

```

Description

This command configures a virtual AP profile.

The WMM traffic management feature is not supported on AP-203H, AP-203R, AP-203RP, AP-207, AP-228, AP-277, 200 Series, 210 Series, 220 Series, 340 Series, 500 Series, 510 Series access points.

WLAN profiles configure WLANs in the form of virtual AP profiles. A virtual AP profile contains an SSID profile which defines the WLAN and an AAA profile which defines the authentication for the

WLAN. You can configure and apply multiple instances of virtual AP profiles to an AP group or to an individual AP.

A named VLAN can be deleted although it is configured in a virtual AP profile. If this occurs the virtual AP profiles becomes invalid. If the named VLAN is added back later the virtual AP becomes valid again.

The `broadcast-filter arp` parameter is enabled by default. If your Mobility Conductor supports clients behind a wireless bridge or virtual clients on VMware devices, you must disable the `broadcast-filter arp` setting to allow those clients to obtain an IP address. In previous releases of ArubaOS, the virtual AP profile included two unique broadcast filter parameters; the `broadcast-filter all` parameter, which filtered out all broadcast and multicast traffic in the air except DHCP response frames (these were converted to unicast frames and sent to the corresponding client) and the `broadcast-filter arp` parameter, which converted broadcast ARP requests to unicast messages sent directly to the client.

The **broadcast-filter arp** setting includes the additional functionality of `broadcast-filter all` parameter, where DHCP response frames are sent as unicast to the corresponding client. This can impact DHCP discover or requested packets for clients behind a wireless bridge and virtual clients on VMware devices. Disable the `broadcast-filter arp` setting using the `wlan virtual-ap <profile> no broadcast-filter arp` command to resolve this issue and allow clients behind a wireless bridge or VMware devices to receive an IP address.

If there is only one VLAN defined, then the Mobility Conductor will send IPv6 RAs as usual. If, however, there are multiple VLANs, then the Mobility Conductor will automatically convert 802.11 multicast frames to unicast. This conversion prevents RA frames from being sent with a multicast key to all clients on the BSSID, which could lead to clients having multiple IPv6 addresses.

Parameter	Description
<code><profile-name></code>	Name of this profile. 1-63 characters default
<code>aaa-profile</code>	Name of the AAA profile that applies to this virtual AP. default
<code>allowed-5g-radio</code>	The 5 GHz radio(s) on which to configure the virtual AP: <ul style="list-style-type: none">■ all—dual 5 GHz band only■ first-5g-radio-only—first 5 GHz band only■ second-5g-radio-only—second 5 GHz band only

Parameter	Description
	<p>all</p> <p>NOTE: This parameter is ignored if the AP has only one 5 GHz radio.</p>
allowed-band	<p>The band(s) on which to use the virtual AP:</p> <ul style="list-style-type: none"> ■ a—5 GHz band only (802.11a) ■ g—2.4 GHz band only (802.11b/802.11g) ■ all—both 2.4 GHz and 5 GHz bands (802.11a and 802.11b/802.11g) ■ none—disable both 2.4 GHz and 5 GHz bands <p>all</p> <p>NOTE: The none option is supported from ArubaOS 8.9.0.0 or later versions.</p>
allowed-band-6ghz (ArubaOS 8.9.0.0 or later versions)	<p>Enable 6 GHz band to use the virtual AP.</p> <p>NOTE: This field is applicable to Wi-Fi 6E APs only.</p>
anyspot-profile	<p>Anyspot Profile associated with this Virtual AP Profile. The anyspot client probe suppression feature decreases network traffic by suppressing probe requests from clients attempting to locate and connect to other known networks.</p>
auth-failure-blacklist-time / auth-failure-denylist-time	<p>Time, in seconds, a client is blocked if it fails repeated authentication. A value of 0 blocks a client indefinitely.</p> <p>0-2,147,483,647 seconds 0</p>

Parameter	Description
band-steering	<p>ARM's band steering feature can encourage or require dual-band capable clients to stay on the 5 GHz band on dual-band APs. This frees up resources on the 2.4 GHz band for single band clients like VoIP phones. Band steering reduces co-channel interference and increases available bandwidth for dual-band clients, because there are more channels on the 5 GHz band than on the 2.4 GHz band. Dual-band 802.11n-capable clients may see even greater bandwidth improvements, because the band steering feature will automatically select between 40MHz or 20 MHz channels in 802.11n networks. This feature is disabled by default, and must be enabled in a Virtual AP profile.</p> <p>The band steering feature supports three steering modes, which can be configured via the steering-mode parameter:</p>

Parameter	Description
	<p>Band steering can be configured on both campus APs and remote APs that have a virtual AP profile set to tunnel, decrypt-tunnel, split-tunnel or bridge forwarding mode. Note, however, that if a campus or remote APs has virtual AP profiles configured in bridge or split-tunnel forwarding mode but no virtual AP in tunnel mode, those APs will gather information about 5G-capable clients independently and will not exchange this information with other APs that also have bridge or split-tunnel virtual APs only.</p> <p>disabled</p>
blacklist/denylist	<p>Enables detection of DoS attacks, such as ping or SYN floods, that are not spoofed death attacks.</p> <p>enabled</p>
blacklist-time/denylist-time	<p>Number of seconds that a client is quarantined from the network after being blocked.</p> <p>0-2,147,483,647 seconds 3600 seconds (1 hour)</p>
broadcast-filter	<p>Filter out broadcast and multicast traffic in the air.</p> <ul style="list-style-type: none"> ■ all <p>NOTE: Do not enable this option for virtual APs configured in bridge forwarding mode. This configuration parameter is only intended for use for virtual APs in tunnel mode. In tunnel mode, all packets travel to the managed device, so the managed</p>

Parameter	Description
	<p>device is able to drop all broadcast traffic. When a virtual AP is configured to use bridge forwarding mode, most data traffic stays local to the AP, and the managed device is not able to filter out that broadcast traffic.</p> <p>IMPORTANT: If you enable this option, you must also enable the <code>Broadcast-Filter ARP</code> parameter in the stateful firewall configuration to prevent ARP requests from being dropped. Note also that although a virtual AP profile can be replicated from a Mobility Conductor to managed device, stateful firewall settings do not. If you select the broadcast-filter all option for a Virtual AP Profile on a Mobility Conductor, you must enable the broadcast-filter arp setting on each individual managed device.</p> <ul style="list-style-type: none"> ■ <code>arp</code> <p>If enabled, all broadcast ARP requests are converted to unicast and sent directly to the client. You can check the status of this option using the <code>show ap active</code> and the <code>show datapath tunnel</code> command. If enabled, the output will display the letter a in the flags column.</p>

Parameter	Description
	<p>Do not enable this option for virtual APs configured in bridge forwarding mode. This configuration parameter is only intended for use for virtual APs in tunnel mode. In tunnel mode, all packets travel to the managed device, so the managed device is able to convert ARP requests directed to the broadcast address into unicast. When a virtual AP is configured to use bridge forwarding mode, most data traffic stays local to the AP, and the managed device is not able to convert that broadcast traffic.</p> <p>all, arp</p> <p>For the option all, the default value is disabled.</p> <p>For the option arp, the default value is enabled.</p>
cellular-handoff-assist	<p>When both the client match and cellular handoff assist features are enabled, the cellular handoff assist feature can help a dual-mode, 3G or 4G-capable Wi-Fi device such as an iPhone, iPad, or Android client at the edge of Wi-Fi network coverage switch from Wi-Fi to an alternate 3G or 4G radio that provides better network access. This feature is disabled by default, and is recommended only for Wi-Fi hotspot deployments.</p> <p>disabled</p>
clone	<p>Name of an existing traffic management profile from which parameter values are copied.</p>

Parameter	Description
deny-inter-user-traffic	<p>Select this check box to deny traffic between the clients using this virtual AP profile.</p> <p>The <code>firewall</code> command includes an option to deny all inter-user traffic, regardless of the Virtual AP profile used by those clients.</p> <p>If the global setting to deny inter-user traffic is enabled, all inter-user traffic between clients will be denied, regardless of the settings configured in the virtual AP profiles. If the setting to deny inter-user traffic is disabled globally but enabled on an individual virtual ap, only the traffic between untrusted users and the clients on that particular virtual AP will be blocked.</p>
deny-time-range	<p>Specify the name of the time range for which the AP will deny access. Time ranges can be defined using the CLI command time-range.</p>
disable-on-6ghz-mesh (ArubaOS 8.9.0.0 or later versions)	<p>If enabled, virtual AP is disabled on 6 GHz band only when AP is provisioned as mesh.</p> <p>NOTE: This field is applicable to Wi-Fi 6E APs only.</p>
dos-prevention	<p>If enabled, APs ignore deauthentication frames from clients. This prevents a successful deauth attack from being carried out against the AP. This does not affect third-party APs.</p> <p>disabled</p>

Parameter	Description
dot11k-profile	Name of an 802.11k profile to be associated with this VAP. default
dynamic-mcast-optimization	Enable or /Disable dynamic multicast optimization. This parameter can only be enabled on a managed device with a PEFNG license. disabled
dynamic-mcast-optimization-threshold	Maximum number of high-throughput stations in a multicast group beyond which dynamic multicast optimization stops. 2-255 stations 6 stations
fdb-update-on-assoc	This parameter enables seamless failover for silent clients, allowing them to re-associate. If you select this option, the managed device will generate a Layer 2 update on behalf of client to update forwarding tables in bridge devices. disabled
forward-mode	Controls whether 802.11 frames are tunneled to the managed device using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the managed device, and Internet access remains local). Select one of the following forward modes:

Parameter	Description
	<ul style="list-style-type: none"><li data-bbox="1133 268 1399 793">■ Tunnel: When an AP is in tunnel forwarding mode, the AP handles all 802.11 association requests and responses. The AP sends all 802.11 data packets, action frames and EAPOL frames over a GRE tunnel to the managed device for processing. The managed device removes or adds the GRE headers, decrypts or encrypts 802.11 frames and applies firewall rules to the user traffic as usual.<li data-bbox="1133 800 1399 1381">■ Bridge: When an AP is in bridge mode, data is bridged onto the local Ethernet LAN. When in bridge mode, the AP handles all 802.11 association requests and responses, encryption or decryption processes, and firewall enforcement. 802.11e and 802.11k action frames are also processed by the AP, which then sends out responses as needed. An AP in bridge mode supports only the 802.1X authentication type.<li data-bbox="1133 1388 1399 1780">■ Split-Tunnel: Data frames are either tunneled or bridged, depending on the destination (corporate traffic goes to the managed device, and Internet access remains local). The AP handles all 802.11 association requests and responses, encryption or decryption, and firewall

Parameter	Description
	<p>enforcement. 802.11e and 802.11k action frames are also processed by the AP, which then sends out responses as needed. An AP in split-tunnel mode supports only the 802.1X authentication type.</p> <ul style="list-style-type: none"> ■ Decrypt-Tunnel: An AP in decrypt-tunnel forwarding mode decrypts and decapsulates all 802.11 frames from a station and sends the 802.3 frames through the GRE tunnel to the managed device, which then applies firewall policies to the user traffic. This mode allows a network to utilize the encryption or decryption capacity the AP while reducing the demand for processing resources on the managed device. APs in decrypt-tunnel forwarding mode also manage all 802.11 association requests and responses, and process all 802.11e and 802.11k action frames. <p>NOTE: Virtual APs in bridge or split-tunnel mode using static WEP should use key slots 2-4 on the managed device. Key slot 1 should only be used with Virtual APs in tunnel mode.</p> <p>tunnel, bridge. split-tunnel decrypt-tunnel tunnel</p>

Parameter	Description
ftm-responder-enable	<p>Enables 802.11mc Fine Timing Measurement (FTM) on radio (responder mode only).</p> <p>This feature is supported on 500 Series, 500H Series, 510 Series, 530 Series, 550 Series, 560 Series, 570 Series, 630 Series, and 650 Series access points.</p> <p>disabled</p>
ha-disc-onassoc	<p>If enabled, home agent discovery is triggered on client association instead of home agent discovery based on traffic from client. Mobility on association can speed up roaming and improve connectivity for clients that do not send many uplink packets to trigger mobility (VoIP clients). Best practices is to leave this parameter disabled, as it increases IP mobility control traffic between managed devices in the same mobility domain. Enable this parameter only when voice issues are observed in VoIP clients.</p> <p>NOTE: <code>ha-disc-onassoc</code> parameter works only when IP mobility is enabled and configured on the managed device.</p> <p>disabled</p>
hs2-profile	<p>Enables or disables a hotspot profile.</p> <p>enabled</p>

Parameter	Description
mobile-ip	Enables or disables IP mobility on a virtual AP. This is enabled by default. L3 mobility service is active on a VAP only if router mobile is also enabled on the managed device. enabled
no	Negates any configured parameter.
openflow-enable	Enables OpenFlow on AP forwarding path.
preserve-vlan	This parameter allows clients to retain their previous VLAN assignment if the client disassociates from an AP and then immediately re-associates either with same AP or another AP on same managed device.
rap-operation	Configures when the virtual AP operates on a remote AP: <ul style="list-style-type: none"> ■ always— Permanently enables the virtual AP (Bridge Mode only). This option can be used for non-802.1X bridge VAPs. ■ backup—Enables the virtual AP if the remote AP cannot connect to the managed device (Bridge Mode only). This option can be used for non-802.1X bridge VAPs. ■ persistent— Permanently enables the virtual AP after the remote AP initially connects to the managed device (Bridge Mode only). This option can be used for any (Open or

Parameter	Description
	<p>PSK or 802.1X) bridge VAPs.</p> <ul style="list-style-type: none"> ■ standard—Enables the virtual AP when the remote AP connects to the managed device. This option can be used for any (bridge or split-tunnel or tunnel or d-tunnel) VAPs. <p>always, backup, persistent, standard standard</p>
ssid-profile	<p>Name of the SSID profile that applies to this virtual AP.</p> <p>default</p>
steering-mode	<p>Band steering supports three different band steering modes.</p> <ul style="list-style-type: none"> ■ Force-5GHz: When the AP is configured in force-5GHz band steering mode, the AP will try to force 5 GHz-capable APs to use that radio band. ■ Prefer-5GHz (Default): If you configure the AP to use prefer-5GHz band steering mode, the AP will try to steer the client to 5G band (if the client is 5G capable) but will let the client connect on the 2.4G band if the client persists in 2.4G association attempts. ■ Balance-bands: In this band steering mode, the AP tries to balance the clients across the two radios in order to best utilize the available 2.4G bandwidth. This feature takes into account the fact that

Parameter	Description
	<p>the 5 GHz band has more channels than the 2.4 GHz band, and that the 5 GHz channels operate in 40 MHz while the 2.5 GHz band operates in 20 MHz.</p> <p>NOTE: Steering modes do not take effect until the band steering feature has been enabled. The band steering feature in ArubaOS versions 3.3.2-5.0 does not support multiple band-steering modes. The band-steering feature in these versions of ArubaOS functions the same way as the default prefer-5GHz steering mode available in ArubaOS 6.0 and later.</p> <p>Force-5 GHz, prefer-5 GHz, balance-bands prefer-5 GHz</p>
strict-compliance	<p>If enabled, the AP denies client association requests if the AP and client station have no common rates defined. Some legacy client stations which are not fully 802.11-compliant may not include their configured rates in their association requests. Such non-compliant stations may have difficulty associating with APs unless strict compliance is disabled.</p> <p>disabled</p>
vap-enable	<p>Enable or disable the virtual AP.</p> <p>enabled</p>

Parameter	Description
vlan	<p>The VLAN(s) into which users are placed in order to obtain an IP address. Enter VLANs as a comma-separated list of existing VLAN IDs or VLAN names. A mixture of names and numeric IDs are not allowed.</p> <p>NOTE: You must add an existing VLAN ID to the Virtual AP profile.</p> <p>1</p>
vlan-mobility	<p>VLAN mobility retains the client VLAN on roaming irrespective of the VAP VLAN, provided the user VLANs are extended. VLAN mobility and mobile IP are mutually exclusive. VLAN mobility does not reuse user firewall sessions on roaming as the sessions will have to be recreated locally on the roamed managed device.</p> <p>disabled</p>
wan-operation	<p>Specify the wan-operation to enable Virtual AP depending on the state of the WAN link.</p> <p>always, backup, primary always</p>
wmm-traffic-management-profile	<p>Specify the WMM Traffic Management Profile to be associated with this Virtual AP Profile.</p>

Example

The following example configures a virtual AP.

```
(host) [md] (config) #wlan virtual-ap corpnet
(host) [md] (Virtual AP profile "corpnet") #vlan 1
```

```
(host) [md] (Virtual AP profile "corpnet") #aaa-profile corpnet
(host) [md] (Virtual AP profile "corpnet") #ftm-enable
```

The following example configures 802.11mc FTM responder.

```
(host) [node] (config) #wlan virtual-ap test
(host) [node] (Virtual AP profile "test") #ftm-responder-enable
(host) [node] (Virtual AP profile "test") #write mem
```

The following example configures the parameters for a 6 GHz band (ArubaOS 8.9.0.0 or later versions).

```
(host) [mynode] (config) #wlan virtual-ap <profile>
(host) [mynode] (Virtual AP profile "profile") #vap-enable
(host) [mynode] (Virtual AP profile "profile") #vlan <vlan-id>
(host) [mynode] (Virtual AP profile "profile") #allowed-band-6ghz
(host) [mynode] (Virtual AP profile "profile") #disable-on-6ghz-mesh
```

Command History

Version	Modification
ArubaOS 8.9.0.0	The following changes were made: <ul style="list-style-type: none"> ■ The <code>allowed-band-6ghz</code> and <code>disable-on-6ghz-mesh</code> parameters were introduced. ■ The none option was added under <code>allowed-band</code> parameter. ■ All instances of <code>blacklist</code> have been replaced with <code>denylist</code>.
ArubaOS 8.8.0.0	The <code>ftm-responder-enable</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Config mode on Mobility Conductor.

wlan wmm-traffic-management-profile

```
wlan wmm-traffic-management-profile <profile-name>  
  background <share>  
  best-effort <share>  
  clone <source>  
  enable-shaping  
  no  
  video <share>  
  voice <share>
```

Description

This command configures bandwidth shaping for WMM access categories.

Bandwidth shaping is only applied on the down-link traffic.

The bandwidth share percentage configuration for WMM traffic management is not supported on 203H Series, 203R Series, 207 Series, 270 Series, 200 Series, 210 Series, 220 Series, AP-228, 340 Series, 500 Series, 510 Series, 570 Series, and AP-518 access points. Therefore, the following parameters do not take effect in these AP platforms: **background<share>**, **best-effort-share <share>**, **video<share>**, and **voice<share>**.

After you configure the WMM traffic management profile, apply it to the virtual AP profile. For WMM traffic management to take effect, you must enable `fair-access` or `preferred-access` parameter under [wlan traffic-management-profile](#).

Parameter	Description
<code>background <share></code>	Bandwidth allocation, in percentage (%), for WMM background access traffic category. 0-100% 5%
<code>best-effort <share></code>	Bandwidth allocation, in percentage (%), for WMM best effort access traffic category. 0-100% 5%
<code>clone <source></code>	Copies the configuration from another WMM Traffic management profile.
<code>enable-shaping</code>	Enables a bandwidth shaping policy so that the allocated bandwidth share is appropriately used. disabled

Parameter	Description
no	Negates any configured parameter.
video <share>	Bandwidth allocation, in percentage (%), for video access traffic category. 0-100% 55%
voice <share>	Bandwidth allocation, in percentage (%), for voice access traffic category. 0-100% 35%

Example

The following example configures a WMM traffic management profile:

```
(host) [md] (config) #wlan wmm-traffic-management-profile test
(host) [md] (WMM Traffic management profile "test") #enable-shaping
(host) [md] (WMM Traffic management profile "test") #background 7
(host) [md] (WMM Traffic management profile "test") #best-effort 10
(host) [md] (WMM Traffic management profile "test") #voice 40
(host) [md] (WMM Traffic management profile "test") #video 43
```

Apply the WMM traffic management profile to the virtual AP profile:

```
(host) [md] (config) #wlan virtual-ap employee
(host) [md] (Virtual AP profile "employee") #wmm-traffic-management-profile
test
```

Enable the `fair-access` or `preferred access` parameter under `wlan traffic-management-profile`:

```
(host) [md] (config) #wlan traffic-management-profile test
(host) [md] (Traffic management profile "test") #shaping-policy fair-access
OR
(host) [md] (Traffic management profile "test") #shaping-policy preferred-
access
```

Apply the traffic management profile to an ap group:

```
(host) [md] (config) #ap-group default
(host) [md] (AP group "default") #dot11a-traffic-mgmt-profile test
```

Related Commands

wms ap

```
wms ap <bssid> mode {suspected-rogue <confidence-level>} [{interfering|manually-  
contained|neighbor|rogue|valid}<add|resend|source>]
```

Description

This command allows you to classify an AP into one of the several categories.

If AP learning is enabled (with the `ids-wms-general-profile learn-ap` command), non-Aruba APs connected on the same wired network as Aruba APs are classified as valid APs. If AP learning is disabled, a non-Aruba AP is classified as an unsecure or suspect-unsecure AP.

Parameter	Description
<bssid>	BSSID of the AP.
mode	Classify the AP into one of the following categories.
suspected-rogue	A suspected rogue AP that is plugged into the wired side of the network but may not be an unauthorized device. Automatic shutdown of rogue APs does not apply to these devices.
<confidence-level>	The confidence level setting for the suspected rogue AP.
interfering	An AP seen in the RF environment but is not connected to the wired network.
manually-contained	Manually enables denial of service from this AP
neighbor	An neighboring AP whose BSSID is known.
rogue	A rogue AP that is unauthorized and is plugged into the wired side of the network. You can configure automatic shutdown of rogue APs in the IDS unauthorized device detection profile.
valid	An AP that is part of the enterprise providing WLAN service.
<add>	Create an entry, if not already present, for the AP classification mode.
<resend>	Resend the mode even if there is no change.
<source>	The source of the manual reclassification. Select one of the following: <ul style="list-style-type: none">■ admin: Manual reclassification is done from the CLI.■ amp: Manual reclassification is done from AirWave.■ restapi: Manual reclassification is done from the REST API.■ webui: Manual reclassification is done from the WebUI. admin

Examples

The following example classifies an interfering AP:

```
(host) [mynode] #wms ap 01:00:00:00:00:00 mode interfering
```

The following example assigns manual reclassification source to the monitored AP:

```
(host) [mynode] #wms ap 80:8d:b7:80:da:74 mode valid source admin
```

wms client

```
wms client <mac>  
  mode {interfering|manually-contain|valid}  
  valid-exempt {insert|remove}
```

Description

This command allows you to classify a wireless client into one of several categories.

ArubaOS can automatically determine client classification based on client behavior, but this command allows you to explicitly classify a client. The classification of a client is used in certain policy enforcement features. For example, if **protect-valid-sta** is enabled in the IDS Unauthorized Device Profile, then clients that are classified as valid cannot connect to non-valid APs.

Parameter	Description
<mac>	MAC address of the client.
mode	Classifies the client into one of the following categories:
interfering	Setting the client mode to <i>interfering</i> makes it part of clients outside the enterprise
manually-contain	Manually enables denial of service to this client.
valid	A client that is part of the enterprise.
valid-exempt	Classifies the client under this option to exempt from Valid Station Protection and Valid Station Misassociation Detection.
insert	Adds the client to the valid-exempt list and exempt from Valid Station Protection and Valid Station Misassociation Detection. If the client exists in the WMS, the classification is set to valid. In case the client does not exist in the WMS, a client entry is created and then the classification is set to valid.
remove	Removes the client from the list of valid-exempt clients.

Example

The following example classifies a client as valid:

```
(host) [mynode] #wms client 00:00:A4:34:C9:B3 mode valid
```

wms export-class

```
wms export-class <filename>
```

Description

This command exports classification information into a file.

This command writes classification data into comma separated values (CSV) files—one for APs and one for clients. You can import these files into the Aruba Mobility Manager system.

Parameter	Description
<filename>	Name of the file into which you want to export classification information.

Example

The following example exports classification data into an AP and a client file:

```
(host) [mynode] #wms export-class class
Exported data to class_ap.csv and class_sta.csv
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

wms export-db

```
wms export-db <filename>
```

Description

This command exports the WMS database to a specified file. The file is exported as an ASCII text file.

Parameter	Description
<filename>	Name of the file into which you want to export the database. The filename plus any extensions must be no longer than 32 characters and may contain only keyboard characters.

Example

The following example exports the WMS database to a file:

```
(host) [mynode] #wms export-db database
Exported WMS DB to database
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

wms fix-db

```
wms fix-db
  table
    ap
    client
    probe
```

Description

This command addresses some types of WMS database corruption.

Parameter	Description
table	Address WMS database table corruption issues for one of the following: <ul style="list-style-type: none">▪ ap: The database table containing monitored AP data.▪ client: The database table containing monitored client data.▪ probe: The database table containing deployed AP data.

Example

The following example exports the WMS database to a file:

```
(host) [mynode] #wms fix-db table ap
This command will try to fix corruption in the WMS database.
This may take several minutes, so it is recommended to run this in off-peak
hours.
Do you want to proceed with this action [y/n]:
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

wms import-db

```
wms import-db <filename>
```

Description

This command imports the specified file into the WMS database. The imported file replaces the WMS database. The imported file must be a valid WMS database file that you previously exported using the `wms export-db` command.

Parameter	Description
<filename>	Name of the file into which you want to import into the database. The filename plus any extensions must be no longer than 32 characters and may contain only keyboard characters.

Example

The following example imports the WMS database from a file:

```
(host) [mynode] #wms import-db database
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

wms reinit-db

wms reinit-db

Description

This command reinitializes the WMS database to its factory default setting. When you use this command, there is no automatic backup of the current database.

Example

The following example reinitializes the WMS database:

```
(host) [mynode] #wms reinit-db  
WMS Database will be re-initialized. Do you want to proceed with this action  
[y/n ]:
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

wms restart-snapshot

```
wms restart-snapshot {ap|rogue-ap|sta}
```

Description

This command restarts periodic snapshot messaging by the WLAN Management System (WMS).

Parameter	Description
ap	Restarts the monitored AP snapshot.
rogue-ap	Restarts the monitored rogue AP snapshot.
sta	Restarts the monitored client snapshot.

Example

The following example restarts snapshot messaging for monitored APs:

```
(host) [mynode] #wms restart-snapshot ap
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Enable or Config mode on Mobility Conductor.

wms test

```
wms test {busy <interval>|lc-poll-interval <interval-time>}
```

Description

This command configures WLAN Management System (WMS) test settings.

Parameter	Description
busy <interval>	Sets a time interval, in seconds, that the WMS is busy.
lc-poll-interval <interval-time>	Sets a polling interval, in minutes, for communication between the WMS and managed devices. The time interval must be between 10-360 minutes.

Example

The following example sets a polling interval of 15 minutes:

```
(host) [mynode] (config) #wms test lc-poll-interval 15
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system	Config mode on Mobility Conductor.

write

```
write {erase [all]|memory|terminal}
```

Description

This command saves the running configuration to memory when the **memory** parameter is used or displays the running configuration on the screen when the **terminal** parameter is used. This command can also be used to erase the running configuration by using the **erase** parameter. For more information about how to return the device to a factory default state, see [wipe](#) command.

Parameter	Description
erase	Erases the running system configuration file. If you specify all , the configuration and all data in controller databases (including the license, WMS, and internal databases) are erased. Starting from ArubaOS 8.11.0.0, the write erase and write erase all commands can be issued only from the /mm and /mm/mynode nodes of the controller.
memory	Saves the current system configuration to memory. Any configuration changes made during this session will be made permanent.
terminal	Displays the current system configuration.

Configuration changes made using the CLI affect only the current session. You must save your changes for them to be retained across system reboots. Changes are lost if the system reboots before saving the changes. To save your configuration changes, use the `write memory` command.

If you use the `write erase` command, the license key management database on the controller is not affected. If you use the `write erase all` command, all databases on the controller are deleted, including the license key management database. If you reset the controller using this command, perform the Initial Setup as described in the *ArubaOS Quick Start Guide*.

If you use the `write terminal` command, all of the commands used to configure controller appear on the terminal. If paging is enabled, there is a pause mechanism that stops the output from printing continuously to the terminal. To navigate through the output, use any of the commands displayed at the bottom of the output, as described below. If paging is disabled, the output prints continuously to the terminal. For more information about the `paging` command, see [paging on page 1069](#).

Key	Description
Q	Exit the display.

Key	Description
U	Page up through the output.
spacebar	Page down through the output.
/	Enter a text string to search for.
N	Repeat the text string to search for.

Example

The following example saves your changes so they are retained after a reboot:

```
(host) [mynode] #write memory
```

The following example deletes the running configuration and returns controller to the factory default settings:

```
(host) [mynode] #write erase
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The write erase and write erase all commands can be issued only from the /mm and /mm/mynode nodes of the controller.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on acontroller.

zeroize-tpm-keys

zeroize-tpm-keys

Description

This command is used to erase the TPM content and render a controller permanently inoperable.

This command can be issued only on a controller which is runs a FIPS build.

Example

Execute the following command to erase the TPM content and render a controller permanently inoperable.

```
(host) [mynode] (config) #zeroize-tpm-keys
The effect of the action you are about to execute is not reversible. Are you
sure you want to implement this function? Press 'y' to proceed : [y/n]: y
This action will void the warranty on the controller and nullify the RMA.
Are you still sure you want to do this?(y/n): y
You are about to wipe the contents of the TPM and render the controller
permanently inoperable. Are you ready to go ahead?(y/n): y
TPM keys have been zeroized. Please reload the controller.
```

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable Mode.

zigbee service-profile

```
zigbee service-profile <service-profile>
  clone <source>
  no
  panid <panid>
  permit-joining {off|on}
  radio-instance {all|external|internal}
  security {disable|enable}
  trust-center-link-key <trust-center-link-key>
```

Description

This command configures or modifies a ZigBee service profile.

Parameter	Description
clone	Copy ZigBee service profile data from another ZigBee service profile.
no	Removes any existing configuration.
panid	ZigBee hexadecimal Pan identity. auto, 0000-FFF0
permit-joining	Allow or disallow joining. off, on
radio-instance	The IoT ZigBee radio instance. all, external, internal
security	Enable or disable ZigBee security. disable, enable
trust-center-link-key <trust-center-link-key>	Zigbee trust center link key consisting of 16 hexadecimal bytes.

Example

The following example configures a ZigBee service profile:

```
(host) [mynode] (config) #zigbee service-profile sample_zb_service_profile
(host) [mynode] (ZigBee Service Profile "sample_zb_service_profile") #panid
auto
(host) [mynode] (ZigBee Service Profile "sample_zb_service_profile")
#permit-joining on
```

```
(host) [mynode] (ZigBee Service Profile "sample_zb_service_profile") #radio-  
instance all  
(host) [mynode] (ZigBee Service Profile "sample_zb_service_profile")  
#security enable
```

Related Commands

Command	Description
show zigbee service-profile	Shows the ZigBee service profile.

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Configuration IoT Data Profile Mode (config-submode).

zigbee socket-device-profile

```
zigbee socket-device-profile <profile-name>
  clone <source>
  inbound <inbound>
  no
  outbound <inbound>
```

Description

This command configures or modifies a ZigBee socket device profile.

Parameter	Description
clone	Copy ZigBee socket device profile data from another ZigBee socket device profile.
inbound <inbound>	Inbound socket from ZigBee inbound socket profile.
no	Server URL for authentication.
outbound <outbound>	Outbound socket from ZigBee outbound socket profile.

Example

```
The following example configures a ZigBee socket device profile:
(host) [mynode] (config) #zigbee socket-device-profile sample_zb_socket_
device_profile
(host) [mynode] (Zigbee Socket Device Profile "sample_zb_socket_device_
profile") #inbound sample_zb_socket_inbound_profile
(host) [mynode] (Zigbee Socket Device Profile "sample_zb_socket_device_
profile") #outbound sample_zb_socket_outbound_profile
```

Related Commands

Command	Description
show zigbee socket-device-profile	Shows the ZigBee socket device profile.

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

zigbee socket-inbound-profile

```
zigbee socket-inbound-profile <profile-name>
  clone <source>
  cluster <cluster>
  endpoint <endpoint>
  no
  profile <profile>
  source-endpoint <source-endpoint>
```

Description

This command configures or modifies a ZigBee socket inbound profile.

Parameter	Description
clone <source>	Copy ZigBee socket inbound profile data from another ZigBee socket inbound profile.
cluster <cluster>	The cluster identity. 0x0000 to 0x7FFF and 0xFC00 to 0xFFFF
endpoint <endpoint>	The destination endpoint. 1 to 254
no	Removes any existing configuration.
profile <profile>	The profile identity. 0x0000 to 0x7FFF and 0xC000 to 0xFFF
source-endpoint <source-endpoint>	The source endpoint. 1 to 254

Example

The following example configures a ZigBee socket inbound profile:

```
(host) [mynode] (config) #zigbee socket-inbound-profile sample_zb_socket_inbound_profile
(host) [mynode] (Zigbee Socket Inbound Profile "sample_zb_socket_inbound_profile") #cluster 0x1234
(host) [mynode] (Zigbee Socket Inbound Profile "sample_zb_socket_inbound_profile") #endpoint 12
(host) [mynode] (Zigbee Socket Inbound Profile "sample_zb_socket_inbound_profile") #profile 34
(host) [mynode] (Zigbee Socket Inbound Profile "sample_zb_socket_inbound_profile") #source-endpoint 56
```

Related Commands

Command	Description
show zigbee socket-inbound-profile	Shows the ZigBee socket inbound profile.

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

zigbee socket-outbound-profile

```
zigbee socket-outbound-profile <profile-name>
  asp-ack
  clone
  cluster
  endpoint
  no
  profile
  source-endpoint
```

Description

This command configures or modifies a ZigBee socket outbound profile.

Parameter	Description
asp-ack	Enables acknowledge of AP.
clone <source>	Copy ZigBee socket outbound profile data from another ZigBee socket outbound profile.
cluster <cluster>	The cluster identity. 0x0000 to 0x7FFF and 0xFC00 to 0xFFFF
endpoint <endpoint>	The destination endpoint. 1 to 254
no	This ID identifies the sender to the server.
profile <profile>	The profile identity. 0x0000 to 0x7FFF and 0xC000 to 0xFFF
source-endpoint <source-endpoint>	The source endpoint. 1 to 254

Example

The following example configures a ZigBee socket outbound profile:

```
(host) [mynode] (config) #zigbee socket-outbound-profile sample_zb_socket_
outbound_profile
(host) [mynode] (Zigbee Socket Outbound Profile "sample") #aps-ack
(host) [mynode] (Zigbee Socket Outbound Profile "sample_zb_socket_outbound_
profile") #cluster 0x1234
(host) [mynode] (Zigbee Socket Outbound Profile "sample_zb_socket_outbound_
profile") #endpoint 12
```

```
(host) [mynode] (Zigbee Socket Outbound Profile "sample_zb_socket_outbound_profile") #profile 34
(host) [mynode] (Zigbee Socket Outbound Profile "sample_zb_socket_outbound_profile") #source-endpoint 56
```

Related Commands

Command	Description

What's New in ArubaOS 8.11.1.0

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.11.1.0.

New Commands in ArubaOS 8.11.1.0

There are no new commands introduced in this release.

Modified Commands in ArubaOS 8.11.0.0

The following commands were modified in ArubaOS 8.11.0.0.

Command	Description
show ap monitor ap-list	The verbose sub-parameter is added to the show ap monitor ap-list ap-name <ap-name> command .
dump-collection-profile	The dump-auto-uploading-profile parameter is introduced.

What's New in ArubaOS 8.11.0.0

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.11.0.0.

New Commands in ArubaOS 8.11.0.0

The following commands were introduced in ArubaOS 8.11.0.0.

Command	Description
ap remote-debug-pkt	This command enables the packet debugging functionality to troubleshoot data packets handled by the AP.
show airgroup query-result	This command displays the list of AirGroup servers that are available for a client.
show ap cellular bearer	This command displays the dual access point name (APN) details on the SIM of an Aruba USB LTE modem.
show ap remote-debug-pkt	This command displays the packet debugging details of an AP.

Modified Commands in ArubaOS 8.11.0.0

The following commands were modified in ArubaOS 8.11.0.0.

Command	Description
aaa authentication via global-config	The max-via-vpn-sessions parameter is introduced.
airgroupprofile	The include-domain-name parameter is introduced.
airgroup	The send-query parameter is introduced.
show airgroup status	The command output is modified to include the Include domain for username policy parameter
show ap bss-table	The command output is modified to include the following flags: z = WPA3-AES-CCM128 BSS Z = WPA3-AES-CCM128 BSS with transition mode
ap regulatory-domain-profile	The oob_switch parameter is introduced.
ap system-profile	<p>The following modifications are introduced:</p> <ul style="list-style-type: none"> ■ The following changes are made to the ipm-power-reduction-step-prio ipm-step parameter: <ul style="list-style-type: none"> ● Replaced radio_2ghz_chain_1x1 with radio_1_chain_1x1 ● Replaced radio_2ghz_chain_2x2 with radio_1_chain_2x2 ● Replaced radio_2ghz_chain_3x3 with radio_1_chain_3x3 ● Replaced radio_2ghz_disable with radio_1_disable ● Replaced radio_2ghz_power_3dB with radio_1_power_3dB ● Replaced radio_2ghz_power_6dB with radio_1_power_6dB ● Replaced radio_5ghz_2_chain_1x1 with radio_2_chain_1x1 ● Replaced radio_5ghz_2_chain_2x2 with radio_2_chain_2x2 ● Replaced radio_5ghz_2_chain_3x3 with radio_2_chain_3x3 ● Replaced radio_5ghz_2_disable with radio_2_disable ● Replaced radio_5ghz_2_power_3dB with radio_2_power_3db ● Replaced radio_5ghz_2_power_6dB with radio_2_power_6db ● Replaced radio_5ghz_chain_1x1 with radio_0_chain_1x1 ● Replaced radio_5ghz_chain_2x2 with radio_0_chain_2x2 ● Replaced radio_5ghz_chain_3x3 with radio_0_chain_3x3 ● Replaced radio_5ghz_chain_4x4 with radio_0_chain_4x4 ● Replaced radio_5ghz_chain_5x5 with radio_0_chain_5x5 ● Replaced radio_5ghz_chain_6x6 with radio_0_chain_6x6 ● Replaced radio_5ghz_chain_7x7 with radio_0_chain_7x7 ● Replaced radio_5ghz_disable with radio_0_disable

Command	Description
	<ul style="list-style-type: none"> ● Replaced radio_5ghz_power_3dB with radio_0_power_3dB ● Replaced radio_5ghz_power_6dB with radio_0_power_6dB ● Replaced radio_6ghz_chain_1x1 with radio_2_chain_1x1 ● Replaced radio_6ghz_chain_2x2 with radio_2_chain_2x2 ● Replaced radio_6ghz_chain_3x3 with radio_2_chain_3x3 ● Replaced radio_6ghz_disable with radio_2_disable ● Replaced radio_6ghz_power_3dB with radio_2_power_3dB ● Replaced radio_6ghz_power_6dB with radio_2_power_6dB ■ The flex-radio-mode {2.4GHz 2.4GHz-and-5GHz 5GHz} parameter is removed for stand-alone controllers only (ArubaOS 8.11.0.0 or later versions).
ap system-profile	The flex-dual {2.4GHz-and-6GHz 5GHz-and-2.4GHz 5GHz-and-6GHz} and flex-dual-mode {2.4GHz-and-6GHz 5GHz-and-2.4GHz 5GHz-and-6GHz Automatic} parameters are introduced to configure flex dual band on AP-615.
clear	The clear lc-cluster bucketmap publish counters command is added to clear the bucketmap publish counters on the cluster.
configure terminal	The ids unauthorized-device-profile parameter is introduced. It includes the following sub-parameters: <ul style="list-style-type: none"> ■ detect-wifi-direct-p2p-groups ■ wifi-direct-network-quiet-time ■ protect-wifi-direct-p2p-groups
crypto-local ipsec-map	The command output of the ipsec-mtu <mtu> parameter is modified to display the MTU size upto 9216 bytes when Jumbo frames are enabled in an IPsec site-to-site tunnel between two managed devices.
firewall	The default value for attack-rate arp parameter is now set to 100.
halt	The halt command can be issued only from the /mm and /mm/mynode nodes of the Mobility Conductor.
iot transportProfile	The blePeriodicTelemetryDisable parameter is introduced to disable periodic telemetry reporting.
ids unauthorized-device-profile	The vendor-specific-ie-exclusion parameter is introduced.
ip default-gateway	Starting from ArubaOS 8.11.0.0, you can execute the ip default-gateway mgmt <nexthop> CLI command to configure the default gateway on the OOB management port for 7000 Seriescontrollers.
reload	The reload command can be issued only from the /mm and /mm/mynode nodes of the Mobility Conductor.

Command	Description
rf dot11-6ghz-radio-profile	The frame-bursting-mode and rts-mode parameters are introduced.
rf dot11a-radio-profile	The frame-bursting-mode and rts-mode parameters are introduced.
rf dot11a-secondary-radio-profile	The frame-bursting-mode and rts-mode parameters are introduced.
rf dot11g-radio-profile	The frame-bursting-mode and rts-mode parameters are introduced.
show aaa authentication via global-config	The command output is modified to display the maximum number of concurrent VIA VPN sessions allowed per user.
show aaa state debug-statistics	The command output is modified to display the number of VIA VPN sessions initiated beyond the assigned limit.
show airgroup cppm	The flag, D is introduced in the output of the command to indicate that the servers share the same username.
show airgroup servers	The following modifications are introduced: <ul style="list-style-type: none"> ■ The username parameter is introduced. ■ The flag, D is introduced in the output of the command to indicate that the servers share the same username.
show ap active	New flags, x , y , and z are introduced to indicate the flex dual band support for the AP-615.
show ap database	All available flags are included in the flags <flags> sub-parameter.
show ap monitor ap-list	The following modifications are introduced: <ul style="list-style-type: none"> ■ The wifi-direct [all] parameter is introduced to the show ap monitor ap-list ap-name <ap name> command, which lists all the WIFI-Direct devices detected by the specified AP. ■ The containment-exclusion parameter is introduced to the show ap monitor ap-list ap-name <ap name> command to display the details of containment exclusion.
show ap monitor debug	The following modifications are introduced: <ul style="list-style-type: none"> ■ The show ap monitor debug status ap-name <ap-name> command includes new counters that show detected and discarded Apple Wireless Direct Link frames. ■ The output of the show ap monitor debug profile-config command includes the details of containment exclusion.
show ap regulatory-domain-profile	The command output is modified to display OOB 6GHz scanning for AP-615 settings.
show crypto-local ipsec-map	The command output of the ipsec-mtu <mtu> parameter is modified to display the MTU size upto 9216 bytes when Jumbo frames are enabled in an IPsec site-to-site tunnel between two managed devices.
show crypto isakmp	The command output is modified to display the number of VIA VPN sessions initiated beyond the assigned limit.

Command	Description
show datapath	The supported range for the MTU parameter in the show datapath tunnel command is increased to 9216 bytes when Jumbo frames are enabled in an IPsec site-to-site tunnel between two managed devices.
show ip route	The command output was modified to display the configured default gateway on the OOB management port for 7000 Series controllers.
show lc-cluster	The bucket distribution all , bucket distribution essid <ssid-name> , and bucketmap publish counters parameters are added to display the bucketmap distribution for the cluster.
show rf dot11a-radio-profile	The command output is modified to display the status of Frame Bursting Mode and RTS Mode .
show rf dot11a-secondary-radio-profile	The command output is modified to display the status of Frame Bursting Mode and RTS Mode .
show rf dot11g-radio-profile	The command output is modified to display the status of RTS Mode .
show rf dot11-6GHz-radio-profile	The command output is modified to display the status of Frame Bursting Mode and RTS Mode .
show snmp trap-list	The command output is modified to display the new SNMP trap, wlsxLicenseThresholdLimitHit , when the license usage is more than 75% of the allocated licenses and before all licenses are used. By default, this SNMP trap is disabled.
show snmp trap-queue	The command output is modified to display the new SNMP trap, wlsxLicenseThresholdLimitHit , when the license usage is more than 75% of the allocated licenses and before all licenses are used. By default, this SNMP trap is disabled.
show web-server	The command output is modified to display the list of enabled cipher suites for the controller.
snmp-server	A new SNMP trap, wlsxLicenseThresholdLimitHit , is introduced to send an alert when the license usage is more than 75% of the allocated licenses and before all licenses are used. By default, this SNMP trap is disabled.
web-server profile	The cipher-suite <cipher(s)> parameter is introduced. The ciphers parameter is removed.
write	The write erase and write erase all commands can be issued only from the /mm and /mm/mynode nodes of the Mobility Conductor.

Deprecated Commands in ArubaOS 8.11.0.0

The following commands were deprecated in ArubaOS 8.11.0.0.

Command	Description

What's New in ArubaOS 8.10.0.0

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.10.0.0.

New Commands in ArubaOS 8.10.0.0

The following commands were introduced in ArubaOS 8.10.0.0:

Command	Description
ap modem-upgrade	This command configures the firmware upgrade of Aruba USB LTE modem.
ap modem	This command upgrades the firmware version of Aruba AP USB LTE modem from the managed device.
gps	This command configures the GPS profile.
show ap cellular connection-lte-logs	This command displays the LTE connection logs for a USB modem connected to an AP.
show ap cellular operator	This command displays the network operator information.
show ap cellular signal	This command displays the signal information for a USB modem connected to an AP.

Command	Description
<u>show ap cellular sim</u>	This command displays information on the SIM card of a USB modem connected to an AP.
<u>show ap cellular stats</u>	This command displays statistics on the transmitted and received data bytes of a USB modem connected to an AP.
<u>show ap cellular status</u>	This command displays the overall status of Aruba USB modem.
<u>show ap cellular cell</u>	This command displays the network cell information for an AP connected to modem.
<u>show ap cellular connection-logs</u>	This command displays the connection logs for a USB modem connected to an AP.
<u>show ap cellular</u>	This command displays the cellular information for debugging purposes.
<u>show ap debug client-kickout-logs</u>	This command displays detailed information on last 12 occurrences of the client kickout (deauthentication) logs per radio in 530 Series, 550 Series, 630 Series, and 650 Series access points.
<u>show ap gps</u>	This command displays the status of GPS profile.
<u>show ap modem-download-log</u>	This command displays the download logs of Aruba USB LTE modem firmware.
<u>show ap modem-upgrade-status</u>	This command displays the status of Aruba USB LTE modem firmware upgrade.
<u>show ap usb verbose</u>	This command displays the details of Aruba USB modem.
<u>show tm</u>	This command displays the monitoring update queue information of the telemetry manager module.
<u>tm</u>	This command is used to configure the maximum queue size for the TM monitoring updates.

Modified Commands in ArubaOS 8.10.0.0

The following commands were modified in ArubaOS 8.10.0.0:

Command	Description
<u>aaa authentication-server radius</u>	The range of the RADIUS server authentication timeout value is increased from 1-30 seconds to 1-120 seconds.
<u>aaa password-policy mgmt</u>	The range of characters in the management user password is increased from 6-64 to 6-128.
<u>ap system-profile</u>	The sub-parameter transfer-enable was added to the dump-collection-profile parameter.

Command	Description
ap system-profile	The following sub-parameters are added to the ipm-power-reduction-step-prio ipm-step parameter: <ul style="list-style-type: none"> ▪ radio_2ghz_disable ▪ radio_5ghz_disable ▪ radio_5ghz_2_chain_1x1 ▪ radio_5ghz_2_chain_2x2 ▪ radio_5ghz_2_chain_3x3 ▪ radio_5ghz_2_disable ▪ radio_5ghz_2_power_3dB ▪ radio_5ghz_2_power_6dB ▪ radio_6ghz_chain_1x1 ▪ radio_6ghz_chain_2x2 ▪ radio_6ghz_chain_3x3 ▪ radio_6ghz_disable ▪ radio_6ghz_power_3dB ▪ radio_6ghz_power_6dB
crypto ipsec	The maximum transmission unit (MTU) range for the <code><max_mtu></code> parameter is increased from 1024-1500 to 1024-2500. This is supported in IPsec site-to-site tunnels for the virtual mobility controllers (VMC)s.
firewall-visibility	The feed <sort-by-bssid> parameter is introduced.
ids dos-profile	The following ghost tunnel attack detection parameters are added: <ul style="list-style-type: none"> ▪ detect-ghosttunnel-client-attack ▪ detect-ghosttunnel-server-attack ▪ ghosttunnel-client-attack-interval ▪ ghosttunnel-client-attack-threshold ▪ ghosttunnel-client-quiet-time ▪ ghosttunnel-server-attack-interval ▪ ghosttunnel-server-attack-threshold ▪ ghosttunnel-server-quiet-time
ip default-gateway	The ip default-gateway mgmt <nexthop> command was modified to configure the default gateway for dedicated OOB management Ethernet port on 7000 Series controllers.
mgmt-user	The management username can have a maximum of 128 characters.
provision-ap	The following parameters are introduced: <ul style="list-style-type: none"> ▪ aruba-modem-apn <aruba-modem-apn> ▪ aruba-modem-plmn <aruba-modem-plmn>
rf dot11g-radio-profile	The airmatch-mode-aware parameter was introduced to enable or disable the AirMatch mode aware.
show ap active type	The airmatch-monitor parameter was introduced to show information of AirMatch monitors.

Command	Description
show ap arm client-match summary	The output of the show ap arm client-match summary and show ap arm client-match summary advanced commands is modified to include the following fields for Wi-Fi 6E APs: <ul style="list-style-type: none"> ■ B5G (T/S) ■ B6G (T/S)
show ap arm client-match unsupported	The command output is modified to include the following flags for Wi-Fi 6E APs: <ul style="list-style-type: none"> ■ B5G ■ B6G
show ap debug airmatch	The output of the command was modified to include the Probe Type parameter under the AirMatch Reporting Radio Band 2.4GHz table.
show ap debug power-table	The command output is modified to include Flash EIRP Limit parameter for 6 GHz bands.
show ap monitor debug	The probe type airmatch-am is introduced in the output of the command under WLAN Interface table.
show ap wifi-uplink-profile	The command output is modified to display the following changes on Wi-Fi 6E APs: <ul style="list-style-type: none"> ■ 6GHz value for Allowed band parameter. ■ WPA3-SAE-AES value for Encryption parameter.
show ap wifi-uplink candidates	The command output is modified to display the following changes on Wi-Fi 6E APs: <ul style="list-style-type: none"> ■ 6GHz value for band parameter. ■ WPA3 value for encryption parameter.
show ap wifi-uplink connection-history	The command output is modified to display 6GHz value for band parameter on Wi-Fi 6E APs.
show ap wifi-uplink neighbors	The command output is modified to display the following changes on Wi-Fi 6E APs: <ul style="list-style-type: none"> ■ 6GHz value for band parameter. ■ WPA3 value for encryption parameter.
show ap wifi-uplink status	The command output is modified to display the following parameter values on Wi-Fi 6E APs: <ul style="list-style-type: none"> ■ wpa3-sae-aes value for Unicast/Multicast Encryption parameter. ■ 6GHz value for Phy parameter.
show crypto-local ipsec-map	Displays PPK ID in the IPsec map configurations on a controller.
show crypto-local isakmp	The ppk parameter was introduced.
show crypto isakmp	The output of the command was modified to display the PPK exchange value.
show firewall-visibility	The show firewall-visibility status command output is modified to include the Sort by Bssid Status parameter.
show ids dos-profile	The following ghost tunnel attack detection parameters are added:

Command	Description
	<ul style="list-style-type: none"> ▪ Detect GHOST TUNNEL SERVER Attack ▪ Detect GHOST TUNNEL CLIENT Attack ▪ GHOST TUNNEL Attack Beacon Detection Threshold ▪ GHOST TUNNEL Attack Probe Request Detection Threshold ▪ GHOST TUNNEL Attack Detection Time Interval ▪ GHOST TUNNEL Attack Detection Time Interval ▪ Ghosttunnel Attack Detection SERVER Quiet Time ▪ Ghosttunnel Attack Detection CLIENT Quiet Time
show interface gigabitethernet	A new output parameter Aruba Certified was introduced.
show memory	The tm parameter is introduced.
show mgmt-server	The tm process is introduced.
	The range of characters in the management username is increased from 1-64 to 1-128.
show mon-serv-mesh-tbl-entry	The 6G parameter is introduced.
show rf dot11g-radio-profile	The output of the show rf dot11g-radio profile command displays the status of AirMatch Mode Aware .
show stm	The mon-update-queue {stats threshold} parameter is deprecated.
stm	The mon-update-queue <threshold> parameter is deprecated.
wlan dot11k-profile	The nb-resp-wide-band-ie is added to include the wide channel bandwidth information element in the neighbor report responses.

Deprecated Commands in ArubaOS 8.10.0.0

The following commands were deprecated in ArubaOS 8.10.0.0:

Command	Description
<code>airgroup active-domain</code>	This parameter configured active domain for an AirGroup cluster.
<pre>airgroup cppm-server aaa rfc-3576-server <rfc3576_server> rfc3576_udp_port <rfc3576_udp_port> server-dead-time <server-dead-time> server-group <server-group> query-interval <1..24></pre>	<p>This parameter configured the following in an AirGroup AAA profile:</p> <p>rfc-3576-server <rfc3576_server>: Configured the RFC 3576 server IP address.</p> <p>rfc3576_udp_port <rfc3576_udp_port>: Configured the UDP port number.</p> <p>server-dead-time <server-deadtime>: Configured server dead time in minutes.</p> <p>server-group<server-group>: Configured the name of the server group.</p>
<pre>domain <string> description <description></pre>	This parameter configured AirGroup domain.

Command	Description
<pre>ip-address <ipaddr> no</pre>	
<pre>show airgroup cppm-server aaa</pre>	<p>This parameter displayed the ClearPass Policy Manager server details.</p> <ul style="list-style-type: none"> ▪ aaa: Displayed the AAA parameters for AirGroup.
<pre>show airgroup effective profiles</pre>	<p>This parameter displayed the effective profiles that were applied at that node.</p>
<pre>policy-entries mac neighborhood <mac> <mac></pre>	<p>This parameter displayed the active policies.</p> <ul style="list-style-type: none"> ▪ neighborhood - Displayed the AP neighborhood to discover the server. ▪ mac - Displayed active policies filtered by specified MAC address.

What's New in ArubaOS 8.9.0.0

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.9.0.0.

New Commands in ArubaOS 8.9.0.0

The following commands were introduced in ArubaOS 8.9.0.0:

Command	Description
rf dot11-6ghz-radio-profile	This command configures Wi-Fi 6E AP radio settings for the 6 GHz frequency band on a 802.11 6 GHz radio profile, including the Adaptive Radio Management (ARM) profile and the high-throughput (802.11n) radio profile.
show ap active 6GHz	This command displays information related to 6 GHz radio that is active on Wi-Fi 6E APs.
wlan 6ghz-rrm-ie-profile	This command configures a Radio Resource Management (RRM) Information Elements (IE) profile to define the information elements advertised by a Wi-Fi 6E AP for 6 GHz band.

Modified Commands in ArubaOS 8.9.0.0

The following commands were modified in ArubaOS 8.9.0.0:

Command	Description
ap mesh-radio-profile	The 6 GHz sub-parameter under prefer-uplink-radio parameter was introduced for Wi-Fi 6E APs.
ap regulatory-domain-profile	The following parameters were introduced for Wi-Fi 6E APs:

Command	Description
	<ul style="list-style-type: none"> ▪ utb_filter_block ▪ valid-6ghz-channel <valid-6ghz-channel>
ids general-profile	The wireless-containment-death-reason parameter was introduced.
iot transportProfile	<p>The following parameters were introduced:</p> <ul style="list-style-type: none"> ▪ usbSerialDeviceTypeFilter <filter> ▪ companyIdentifierFilter <filter> ▪ serviceUUIDFilter <filter> ▪ macOuiFilter <filter> ▪ localNameFilter <filter>
logging	The tls sub-parameter was introduced to ensure secure transport mechanism to send device logs to an external logging server.
rf arm-profile	The default-6ghz parameter was introduced.
show ap active	The 6GHz parameter was introduced for Wi-Fi 6E APs.
show ap allowed-channels	<p>The command output was modified to include the following:</p> <ul style="list-style-type: none"> ▪ Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values respectively under PHY Type parameter ▪ Added 6GHz value under PHY Type parameter for Wi-Fi 6E APs.
show ap arm history	The Phy-Type parameter was introduced.
show ap arm neighbors	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> ▪ Added phy-type parameter. ▪ Added 2.4GHz, 5GHz, and 6GHz values for phy-type parameter.
show ap arm rf-summary	<p>The command output was modified to include the following parameters:</p> <ul style="list-style-type: none"> ▪ band ▪ phy-type
show ap arm scan-times	<p>The command output was modified to include following parameters:</p> <ul style="list-style-type: none"> ▪ band

Command	Description
	<p>The command output was modified to include the UTB filter results, and based on the band selected the following parameters were displayed:</p> <ul style="list-style-type: none"> ▪ First blocked channel ▪ Last blocked channel
show ap association	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ▪ Added 2, 5, and 6 values to denote 2.4 GHz, 5 GHz, and 6 GHz bands respectively for the phy <phy> parameter. ▪ Added 2.4GHz, 5GHz, and 6GHz values for phy and phy_cap output parameters.
show ap bss-table	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> ▪ Replaced 802.11g and 802.11a with 2.4GHz and 5GHz parameters respectively. ▪ Added 6Ghz parameter for Wi-Fi 6E APs.
show ap config	<p>The command output was modified to display the 2.4GHz, 5GHz, 5GHz-secondary, and 6GHz parameters.</p>
show ap debug airmatch	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ▪ The Radio 2 interface was displayed for 6 GHz band on Wi-Fi 6E APs. ▪ The command outputs were modified to include 6 GHz values for Wi-Fi 6E APs. ▪ The show ap debug airmatch channel-lists ap-name <ap-name> command output was modified to include u channel flag and 6 GHz data for Wi-Fi 6E APs.
show ap debug bss-config	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ▪ Replaced phy with band/ht-mode/bandwidth parameter in the command output. ▪ Replaced g and a with 2.4GHz and 5GHz values in the command output. ▪ Added 6GHz value in the command output for Wi-Fi 6E APs. ▪ Added x flag in the command output parameter for Wi-Fi 6E APs.

Command	Description
show ap debug received-reg-table	The 6g value was introduced under PHY Type output parameter for Wi-Fi 6E APs.
show ap essid	The command output was modified to include the MBSSID Tx BSS parameter for Wi-Fi 6E APs.
show ap-group	The command output was modified to display the 802.11 6GHz radio profile parameter.
show ap load-balancing	The command output was modified to include the following changes: <ul style="list-style-type: none"> ▪ Replaced phy with Phy-type parameter. ▪ Replaced a and g with 5GHz and 2.4GHz values. ▪ Introduced 6GHz value for Wi-Fi 6E APs.
show ap mesh active	The command output was modified to display the RF bands as 2.4 GHz , 5 GHz , or 6 GHz .
show ap mesh neighbors	The following changes were made: <ul style="list-style-type: none"> ▪ All instances of Blacklisted-neighbour have been replaced with Denylisted-neighbour. ▪ The output of the command was modified to display the AP Name and Band parameters.
show ap monitor active-laser-beams	The 6GHz value was added to band <band> parameter for Wi-Fi 6E APs.
show ap monitor ap-list	The command output was modified to include the following changes: <ul style="list-style-type: none"> ▪ Removed chan and phy-type parameters. ▪ Added band/chan/ch-width/ht-type and 6Ghz capable parameters for Wi-Fi 6E APs.
show ap monitor association	The command output was modified to include the following changes: <ul style="list-style-type: none"> ▪ Replaced phy-type with band ▪ Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values for band output parameter respectively. ▪ Introduced 6GHz value under band parameter for Wi-Fi 6E APs.

Command	Description
show ap monitor client-list	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced phy-type with band/chan/ch-width/ht-type parameter. Introduced 6GHz capable parameter for Wi-Fi 6E APs.
show ap monitor debug	<p>The output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced phy-type with band/chan/ch-width/ht-type. Replaced 802.11g and 802.11a with 2.4GHz and 5GHz. Introduced 6GHz parameter for Wi-Fi 6E APs.
show ap monitor mesh-list	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced phy-type with band/chan/ch-width/ht-type parameter. Introduced 6GHz capable parameter for Wi-Fi 6E APs.
show ap monitor pot-ap-list	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced channel and phy with band/chan parameter. Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values for band/chan output parameter respectively. Introduced 6GHz value under band/chan parameter for Wi-Fi 6E APs.
show ap monitor pot-client-list	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced channel with band/chan parameter. Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values for band output parameter respectively. Introduced 6GHz value under band/chan parameter for Wi-Fi 6E APs.
show ap monitor scan-info	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced 802.11g and 802.11a with 2.4GHz and 5GHz values for Phy

Command	Description
	<p>Type output parameter respectively.</p> <ul style="list-style-type: none"> Introduced 6GHz value under Phy Type parameter for Wi-Fi 6E APs.
<p>show ap radio-database</p>	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced band [a g] with band [2.4GHz 5GHz 6GHz] parameters. Replaced Radio 0 Band Ch/EIRP/MaxEIRP/Clients with Radio 0 Band/Chan/HT-Type/EIRP in the output parameter. Replaced Radio 1 Band Ch/EIRP/MaxEIRP/Clients with Radio 1 Band/Chan/HT-Type/EIRP in the output parameter. Replaced Radio 2 Band Ch/EIRP/MaxEIRP/Clients with Radio 2 Band/Chan/HT-Type/EIRP in the output parameter.
<p>show ap radio-summary</p>	<p>The command was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced dot11a and dot11g with 5GHz and 2.4GHz parameters respectively. Introduced 6GHz parameter for Wi-Fi 6E APs. Introduced 6GHz value under Band output parameter for Wi-Fi 6E APs.
<p>show ap regulatory-domain-profile</p>	<p>The command output was modified to display the following new parameters for Wi-Fi 6E APs:</p> <ul style="list-style-type: none"> UTB Filter Blocking Selection Valid 6GHz channel Valid 6GHz 40MHz channel pair Valid 6GHz 80MHz channel group Valid 6GHz 160MHz channel group
<p>show ap remote bss-table</p>	<p>The command output was modified to include the following changes:</p> <ul style="list-style-type: none"> Replaced phy parameter with band/ht-mode/bandwidth. Added x and 3 flags.
<p>show ap remote debug association</p>	<p>The command output was modified to display the following values for phy parameter:</p> <ul style="list-style-type: none"> 2.4GHz

Command	Description
	<ul style="list-style-type: none"> ▪ 5GHz ▪ 6GHz (For Wi-Fi 6E APs)
show ap remote debug bss-config	<p>The command output was modified to include the following:</p> <ul style="list-style-type: none"> ▪ Replaced phy parameter with band/ht-mode/bandwidth. ▪ Added x and 3 flags.
show ap remote debug neighbor-cache	<p>The command output was modified to include the Band parameter.</p>
show ap spectrum channel-metrics	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs.</p>
show ap spectrum channel-summary	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs.</p>
show ap spectrum client-list	<p>The following changes were introduced:</p> <ul style="list-style-type: none"> ▪ The band <band> parameter was added. ▪ Replaced phy-type with band in the command output parameter.
show ap spectrum debug status	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs.</p>
show ap spectrum device-list	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs..</p>
show ap spectrum device-log	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs.</p>
show ap spectrum device-history	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs.</p>
show ap spectrum interference-power	<p>Introduced the 6ghz sub-parameter under freq-band parameter for Wi-Fi 6E APs.</p>
show ap snmp	<p>The command output was modified to include 2.4GHz, 5GHz, and 6GHz values for Channel parameter.</p>
show ap virtual-beacon-report	<p>The 6 GHz capable parameter was introduced.</p>
show ap wmm-flow	<p>The following parameters were introduced:</p>

Command	Description
	<ul style="list-style-type: none"> ▪ 2.4GHz ▪ 5GHz ▪ 6GHz (For Wi-Fi 6E APs)
<u>show ids general-profile</u>	The wireless-containment-deauth-reason parameter was introduced. .
<u>show ip route</u>	The command output was modified to display the configured default gateway on the OOB management port for 7280 controllers.
<u>show wms ap</u>	The following changes were introduced: <ul style="list-style-type: none"> ▪ Introduced Band parameter in the output of the show wms ap list and show wms ap tree commands. ▪ Introduced 2.4GHz, 5GHz, and 6GHz values under Band parameter.
<u>show wms client</u>	The command output was modified to include the following changes: <ul style="list-style-type: none"> ▪ Introduced Band parameter in the output of show wms client list command. ▪ Introduced Band/Chan/HT-Type/HT-Sec-Chan parameter in the output of show wms client <mac> command. ▪ Introduced 2.4GHz, 5GHz, and 6GHz values under Band parameter.
<u>show wms probe</u>	The command output was modified to include the following changes: <ul style="list-style-type: none"> ▪ Introduced Band/HT-Type parameter. ▪ Introduced 2.4GHz, 5GHz, and 6GHz values under Band parameter.
<u>show wms rogue-ap</u>	The command output was modified to include the following changes: <ul style="list-style-type: none"> ▪ Introduced Band parameter under show wms rogue-ap list command. ▪ Introduced 2.4GHz, 5GHz, and 6GHz values under Band parameter. ▪ Introduced Band/Chan/HT-Type/HT-Sec-Chan parameter under show wms rogue-ap <bssid> command.
<u>show logging</u>	The output sub-parameter tls was introduced.

Command	Description
show running-config	The command output was modified to display the configured default gateway on the OOB management port for 7280 controllers.
wlan dot11k-profile	The ap-chan-rpt-6ghz parameter was introduced.
wlan bcn-rpt-req-profile	The values auto , 81 , 115 , and 131 were introduced for the reg-class parameter.
wlan virtual-ap	The following changes were made: <ul style="list-style-type: none"> Introduced allowed-band-6ghz and disable-on-6ghz-mesh parameters. Introduced none option under allowed-band parameter.

What's New in ArubaOS 8.8.0.0

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.8.0.0.

New Commands in ArubaOS 8.8.0.0

The following commands were introduced in ArubaOS 8.8.0.0:

Command	Description
acl-debug alias-rule-hits type	This command allocates hits-indices for role, route, and session ACEs expanded in an ACE with aliases.
allowed-address-list	This command configures addresses exempted when the deny-inter-user-bridging is enabled.
iot-sniffer radio	This command configures the IoT sniffer function on the radio of an AP.
ip dhcp reserved	This command configures DHCP server device reservations. You can use IP reservation to manually bind IP addresses from a DHCP pool to a client MAC address.
ipv6 dhcp relay-option	This command configures the DHCPv6 relay options by using the XML definition file containing DHCPv6 Option 18 (Circuit ID) and Option 37 (Remote ID) sub-type options.
managed-device delete image	This command deletes the image stored in Mobility Master file system.
no allowed-address-list	This command is used to remove the IP addresses that were added using <code>allowed-address-list</code> command.
show ap antenna status	This command is introduced to display the operational status of AP antennas.
show ap debug iot-sniffer	This command displays IoT sniffer information on the AP.

Command	Description
show ap remote debug web-server-config	This command displays the web server profile configurations on the AP.
show ap remote debug wired-port-down-state	This command displays the wired port bounce configurations that are forwarded from the controller and AP's wired port status.
show managed-device images	This command displays the images of managed devices stored in the Mobility Master file server.
show aaa authentication downloaded-cp-profiles	This command enables users to push CP profiles along with the user role from CPPM.
show snmp trap-group	This command displays the configured SNMP trap groups.

Modified Commands in ArubaOS 8.8.0.0

The following commands were modified in ArubaOS 8.8.0.0:

Command	Description
airgroup	The version parameter was introduced.
ap mesh-radio-profile	The following changes were introduced: <ul style="list-style-type: none"> ■ The optimize-scan-interval parameter was introduced. ■ The functionality of reselect-any-time and subthreshold-only reselection-modes were changed. ■ The mesh-mobility, mobility-beacon-miss <mobility-beacon-miss>, and mobility-rssi <mobility-rssi> parameters are introduced.
ap system-profile	The following parameters are introduced: <ul style="list-style-type: none"> ■ wired-poe-bounce-interval <wired-poe-bounce-interval> ■ wired-port-bounce-interval <wired-port-bounce-interval> ■ seslmagotag-esl-radio-coexistence ■ seslmagotag-esl-tls-auth ■ seslmagotag-esl-tls-fqdn-verify The value, 127, was added to the seslmagotag-esl-channel parameter.
ap provisioning-profile	The following parameters were added: <ul style="list-style-type: none"> ■ apdot1x-timeout-bypass ■ apdot1x-timeout-retries
clear	The ip dhcp binding ip-address <ip-address> parameter is introduced.
crypto-local ipsec-map	The session-acl sub-parameter was added in the ip access-group parameter.
est	The output is modified to specify the keytype in a csr attribute. The default server configuration is accepted first during the enrollment/re-enrollment process. If the server does not provide the csr attribute, then the user configured csr attribute is accepted.

Command	Description
firewall	The session-spread parameter is added.
interface vlan	The ipv6-relay-option parameter is introduced.
iot transportProfile	<p>The following parameters are introduced:</p> <ul style="list-style-type: none"> ■ azure-dps-auth-type group-enrollment symmetric-key ■ azure-dps-id-scope ■ authentication-mode ■ client-secret ■ bleDataForwarding ■ perFrameFiltering <p>The following deviceClassFilters are introduced:</p> <ul style="list-style-type: none"> ■ google ■ minew <p>The Azure-IoTHub server type is introduced.</p>
ip access-list route	The output is modified to display a brief description of the route ACL.
ip access-list session	The output is modified to display a brief description of the session ACL.
ntp	The fqdn sub-parameter is introduced.
provision-ap	<p>The following parameters were added:</p> <ul style="list-style-type: none"> ■ apdot1x-timeout-bypass ■ apdot1x-timeout-retries
rf arm-profile	A new parameter, voip-aware-scan-timer , is added to enable users to set the VoIP Aware Scan Timer range between 50 ms-1000 ms.
rf dot11a-radio-profile	The zero-wait-dfs parameter is introduced.
rf dot11g-radio-profile	The iot-coex-enable parameter is introduced.
show acl acl-table	A new parameter, verbose , shows verbose ACL information.
show airgroup status	A new output parameter, AirGroup version , is introduced to display the active AirGroup version.
show airmatch debug optimization	A new flag, A is introduced to indicate the radios assigned by AirMatch.
show airmatch debug reporting-radio	A new flag, A is introduced to indicate the radios assigned by AirMatch.
show airmatch debug solver feasibility	A new output parameter, HE Pooling Chan Feas is introduced to display the number of HE pooling channels.
show amon-sender	The output parameter, TAG of the show amon-sender stats-counters-all command gets incremented when there are RTLS frames from AMON receiver.
show ap arm scan-times	The output of the command is modified to display the zero-wait DFS channel details.

Command	Description
show ap database	A new flag, b , was introduced to show AP1x timeout.
show ap debug system-status	The following modifications are introduced: <ul style="list-style-type: none"> ■ The output of the command has been modified to display the NSS CPU usage. ■ The output of the command has been modified to display Ethernet related details.
show ap mesh neighbors	The output of the command is modified to display the m flag.
show ap mesh-radio-profile	The output of the command is modified to display the following parameters: <ul style="list-style-type: none"> ■ Mesh Mobility ■ Mobility RSSI Threshold ■ Mobility Beacon Miss Number
show ap monitor debug	The output of the command is modified to display the zero-wait DFS channel details.
show ap system-profile	The output of the command is modified to display the following parameters: <ul style="list-style-type: none"> ■ Wired Port Down-Time By Shutdown Ethernet Link ■ Wired Port Down-Time By Shutdown POE
show ap tech-support	The output of the command is modified to display Ethernet related details.
show crypto-local isakmp	The max-allowed-negotiations parameter was added to show the maximum on-going exchanges allowed at a time.
show datapath	The output of the command is modified to display allowed-address-list .
show firewall	The output of the command is modified to include the DPI classifications.
show gsm debug	The output of the command was modified to include dhcpcd_via_info parameter.
show ip dhcp	The reserved parameter is introduced to display DHCP server device reservations.
show ipv6 dhcp	The following parameters are introduced: <ul style="list-style-type: none"> ■ helper <id> ■ relay <counters> ■ relay-option ■ vlan <id>
show master-l3redundancy/show conductor-l3redundancy	The show master-l3 redundancy switches command now allows users to see the L3 redundant peer controller details along with active and standby controller details.
show snmp trap-list	The output of the command was modified to include a new SNMP trap, wlsxClusterVlanProbeStatus .

Command	Description
show upgrade-profile	The output of the command is modified to display the Download AOS Image from MM parameter.
show wlan he-ssid-profile	The output of the command is modified to include status of uplink MU-MIMO transmission.
show wlan virtual-ap	The output of the command is modified to display the Fine Timing Measurement (802.11mc) Responder Mode parameter.
show wms ap	The output of the show wms ap <bssid> and show wms ap list commands are modified to display the following parameters: <ul style="list-style-type: none"> ■ Match-Type ■ Match-Source ■ Match-Time
snmp-server	The trap-group <SNMP trap group name> parameter is introduced.
upgrade-profile	The download_from_mm parameter is added.
user-role	A new parameter, via-dhcp , is added to support external DHCP server address pool instead of internal L2TP pool
wlan he-ssid-profile	The he-ul-mu-mimo parameter is introduced.
wlan virtual-ap	The ftm-responder-enable parameter is introduced.
user-role	The following parameters were added: <ul style="list-style-type: none"> via-dhcp robust-age-out
wms ap	The <source> sub-parameter is introduced.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.7.0.0.

New Commands in ArubaOS 8.7.0.0

The following commands were introduced in ArubaOS 8.7.0.0:

Command	Description
airslice	This command is introduced to configure or modify an Air Slice profile.
ap debug radio-diag-log	This command is introduced to collect WLAN firmware diagnostic logs to facilitate firmware debugging.
ap get-crash-dumps	This command is introduced to allow AP crash dump files to be transferred to the controller flash memory on demand from the AP flash memory.
ap mesh-accesslist-profile	This command is introduced to configure or modify a mesh access list profile.
ap usb-acl-prof	This command is introduced to configure an AP USB ACL profile.
ap usb-profile	This command is introduced to configure an AP USB profile.
ble service-profile	This command is introduced to configure BLE service profile.
ca-bundle	This command is introduced to upgrade the trusted CA certificates.
dot1x-transactions-monitor	This command is introduced to start or stop displaying the rate statistics under the show dot1x-transactions-monitor command.
dot1x-transactions-monitor set	This command is introduced to provide the rate statistics interval duration and the total duration of a 802.1X transaction.
ip-reputation deny	This command is introduced to deny connections matching malicious IP addresses.
lc-rap-pool-v6	This command is introduced to configure the Remote AP inner IPv6 pool for cluster deployment.
show airslice	This command is introduced to display the details of an Air Slice profile.
show ap debug ble-input-filter-stats	This command is introduced to display the input-filter information in the BLE table.
show ap debug client-info	This command is introduced to display all the details of a specific client in WLAN driver, for client debugging.
show ap debug radio-diag-log status	This command is introduced to display the current diagnostic logging status of an AP.

Command	Description
<u>show ap debug usb-device-mgmt</u>	This command is introduced to display the debugging information of USB devices managed on an AP.
<u>show ap get-crash-dumps-status</u>	This command is introduced to display the status of the crash dump file transfers to a controller.
<u>show ap mesh-accesslist-profile</u>	This command is introduced to display the details of a mesh access list profile.
<u>show ap usb-acl-prof</u>	This command is introduced to display the AP USB ACL profile.
<u>show ap usb-device-mgmt</u>	This command is introduced to display the USB devices managed on an AP.
<u>show ap usb-prof</u>	This command is introduced to display AP USB profile.
<u>show ble service-profile</u>	This command is introduced to display the details of a BLE service profile.
<u>show ca-bundle version</u>	This command is introduced to display the version number of trusted CA certificates.
<u>show dot1x-transactions-monitor</u>	This command is introduced to display the rate statistics, per second, for a 802.1X user.
<u>show datapath cluster details</u>	This command is introduced to display detailed values of heartbeat sent or received count along with the sequence number of missed and delayed packets for all the connected peers.
<u>show datapath cluster heartbeat counters</u>	This command is introduced to display information related to cluster heartbeat counters.
<u>show lc-cluster history</u>	This command is introduced to display the history of the connection and disconnection events with a reason and the time stamp.
<u>show log peer-debug</u>	This command is introduced to display the logs of MAC-based debugging in IKE.
<u>show zigbee service-profile</u>	This command is introduced to display the ZigBee service profile.
<u>show zigbee socket-device-profile</u>	This command is introduced to display the ZigBee socket device profile.
<u>show zigbee socket-inbound-profile</u>	This command is introduced to display the ZigBee socket inbound profile.
<u>show zigbee socket-outbound-profile</u>	This command is introduced to display the ZigBee socket outbound profile.
<u>zigbee service-profile</u>	This command is introduced to configure a ZigBee service profile.
<u>zigbee socket-device-profile</u>	This command is introduced to configure a ZigBee socket device profile.

Command	Description
zigbee socket-inbound-profile	This command is introduced to configure a ZigBee socket inbound profile.
zigbee socket-outbound-profile	This command is introduced to configure a ZigBee socket outbound profile.

Modified Commands in ArubaOS 8.7.0.0

The following commands were modified in ArubaOS 8.7.0.0:

Command	Description
aaa authentication captive-portal	Captive portal authentication was supported for VAPs in the bridge forwarding mode.
aaa authentication via connection-profile	The addr sub-parameter is modified to include IPv6 address.
aaa profile	The ageout-bridge-user parameter is introduced.
airmatch profile	The he-pooling-client-density parameter is introduced.
ap ble-init-action	The following parameters are introduced: <ul style="list-style-type: none"> ▪ input-filter-disable ▪ input-filter-enable
ap-group	The following parameters are introduced: <ul style="list-style-type: none"> ▪ airslice-profile ▪ airslice-visibility record-limit ▪ mesh-accesslist-profile ▪ usb-profile
ap mesh-cluster-profile	The rf-band all and rf-split5G-band-range parameters are introduced.
ap mesh-radio-profile	The prefer-uplink-radio parameter is introduced.
ap-name	The following parameters are introduced: <ul style="list-style-type: none"> ▪ airslice-profile ▪ mesh-accesslist-profile
ap provisioning-profile	The master-preference parameter is introduced.
ap system-profile	The following parameters are introduced: <ul style="list-style-type: none"> ▪ disable-factory-reset ▪ he-pooling-enable ▪ itm-enable The following parameters were modified: <ul style="list-style-type: none"> ▪ telnet

Command	Description
	<ul style="list-style-type: none"> ▪ recovery-mode
controller-ble opmode	The beaconing parameter is removed.
crypto ipsec	The rekey parameter is introduced to configure IPsec rekey interval.
crypto isakmp	The rekey parameter is introduced to configure IKE rekey interval.
firewall	<p>The following parameters are introduced:</p> <ul style="list-style-type: none"> ▪ enable-gre-inner-pkt-frag ▪ deny-needfrag-df-gre-xmit-icmp ▪ deny-needfrag-df-gre ▪ deny-needfrag-gre-xmit-icmp ▪ deny-needfrag-gre
interface vlan	The dns-sl sub-parameter is added.
iot-manager	<p>The following parameters are added:</p> <ul style="list-style-type: none"> ▪ export ▪ replace-ap
iot transportProfile	<p>The following parameters are introduced:</p> <ul style="list-style-type: none"> ▪ ZSDFilter ▪ dataFilter <p>The following device class filters are introduced:</p> <ul style="list-style-type: none"> ▪ exposure-notification ▪ serial-data ▪ wiliot ▪ ZSD <p>The enableOnController parameter is removed.</p>
lc-cluster group-profile	The default value of the heartbeat-threshold parameter was changed to 900 ms.
logging	MAC-based debugging support in ISAKMPD is introduced. This feature will enable in debugging issues if APs are unable to form a tunnel with a controller in a scale setup.
mgmt-server	The ap-app-stats parameter is introduced.
provision-ap	The master-preference parameter was introduced.
rf arm-profile	<p>The following parameters were added:</p> <ul style="list-style-type: none"> ▪ cm-he-pooling-signal-delta ▪ cm-he-pooling-snr-thresh

Command	Description
show airgroup	The output of the show airgroup command is modified to include the new sub-parameter ppm under the parameter internal-state statistics .
show airgroupprofile	The output of the show airgroupprofile command is modified to include the following sub-parameters under the network default parameter: <ul style="list-style-type: none"> ▪ Enter MAC-Address or MAC-OUI to be blacklisted ▪ Configure max allowed IP per device. Default: 4 ▪ Configure max allowed tokens/cache per device (Default: 40)
show airmatch debug schedule	The output of the show airmatch debug schedule switch-info command is modified to include IPv6 address.
show ap active	The output parameters Radio 0 Band Ch/EIRP/MaxEIRP/Clients , Radio 1 Band Ch/EIRP/MaxEIRP/Clients , and Radio 2 Band Ch/EIRP/MaxEIRP/Clients include the following details: <ul style="list-style-type: none"> ▪ MPP: Indicates mesh-enabled radio of a mesh portal. ▪ MPC: The mesh point radio that has a parent link. ▪ MPA: The mesh point radio without a parent link.
show ap arm client-match history	The command output is modified to display information on clients having only IPv4 or IPv6 address, or a combination of both.
show ap database	The command displays two new flags, t and r to indicate Temperature Restriction and Power Restriction respectively.
show ap-group	The output is modified to include the following parameters: <ul style="list-style-type: none"> ▪ Mesh Accesslist Profile ▪ AirSlice Profile
show ap mesh active	The command displays a detailed output of all parameters only if mesh -enabled radios are configured.
show ap mesh neighbors	The output is modified to include the Radio parameter.
show ap mesh topology	The output is modified to include the Radio parameter.

Command	Description
show ap monitor	The following command outputs are modified to include ipv6 field: <ul style="list-style-type: none"> ▪ show ap monitor arp-cache ap-name <ap_name> ▪ show ap monitor debug status ap-name <ap_name> ▪ show ap monitor containment-info ap-name <ap_name>
show ap-name	The output is modified to include the following parameters: <ul style="list-style-type: none"> ▪ Mesh Accesslist Profile ▪ AirSlice Profile
show ap power-mgmt-statistics	The output is modified to display the ITM Status parameter.
show ap provisioning-profile	The output is modified to display the master preference of the AP.
show ap remote debug client-mgmt-counters	The following ASAP AP APP stats messages and record counters are introduced: <ul style="list-style-type: none"> ▪ total ▪ null sap ▪ empty ▪ error ▪ queued ▪ sent
show ap virtual-beacon-report	The command output is modified to also display IPv6 address of the AP.
show controller-ip	The command output is modified to display Switch IP as Switch IPv4 .
show datapath	The command outputs are modified to include the following: <ul style="list-style-type: none"> ▪ A new flag, X is introduced for show datapath tunnel command. ▪ The show datapath session dpi command displays the AirSlice ID.
show firewall	The output was modified to include the following parameters: <ul style="list-style-type: none"> ▪ Enable GRE Inner Frame Fragmentation ▪ Drop Larger than GRE MTU DF frame, send ICMP Err ▪ Drop Larger than GRE MTU DF frame ▪ Drop Larger than GRE MTU frame, send ICMP Err ▪ Drop Larger than GRE MTU frame

Command	Description
show gsm debug	The dual_controller_ip output parameter is introduced in the show gsm debug channel cluster command.
show gsm lookup	The output of the following commands are modified to display IPv6 address of the AP: <ul style="list-style-type: none"> ▪ show gsm lookup channel radio key radio_bssid <radio_bssid> ▪ show gsm lookup channel sta_mac_address <sta_mac_address>
show interface tunnel	The following parameters are introduced: <ul style="list-style-type: none"> ▪ Tunnel stats last fetched from SOS ▪ RxBytes:, TxBytes:, Encaps:, Decaps:
show iot-manager	The ble-services parameter is added.
show iot transportProfile	The following parameters are introduced: <ul style="list-style-type: none"> ▪ Zigbee Socket Device Filter ▪ Data Filter The following device class filters are introduced: <ul style="list-style-type: none"> ▪ exposure-notification ▪ wiliot ▪ ZSD The Enable BLE on Controller parameter is removed.
show ip access-list	The following parameters are introduced for VAPs in bridge mode: <ul style="list-style-type: none"> captiveportalbridge logon-control-bridge The global-geolocation-acl parameter is introduced.
show lc-cluster	The functionality of heartbeat counters parameter is modified.
show lc-rap-pool	The command output is modified to display IPv6 address used in Remote AP inner pool.
show master-local stats / show conductor-local stats	The output of the command is modified to include IPv6 address.
show memory	The as_visibility parameter is introduced.
show ssh	The hmac-sha2-256 parameter is introduced.
show upgrade managed-devices	The ca-bundle parameter is introduced.
show vlan-assignment	The IP Timeout Count and Time Full output parameters are introduced.

Command	Description
show vlan mapping	The IP Timeout , Max IP Timeouts and Full Period output parameters are introduced.
show whitelist-db cpsec-status/show allowlist-db cpsec-status	The output of the command is modified to include the following fields: <ul style="list-style-type: none"> ▪ My IPv6-Address ▪ Master IPv6-Address ▪ IPv6 LMS List
show wms rogue-ap	The output of the show wms rogue-ap <bssid> command is modified to display IPv6 address under Match IP field.
ssh	The command is modified to support SHA-2 authentication.
vlan-name	The ip-timeout , max-ip-timeouts and full-period sub-parameters are introduced.
vpnip	The v6 <vpncipv6> parameter is added.
web-server profile	TLS v1.2 is now the default ssl-protocol in the web-server profile. TLS v1 and TLS v1.1 is disabled by default.
wlan ssid-profile	The advertise-ap-name parameter is modified to include AP names in probe response frames.
upgrade managed-devices	The ca-bundle parameter is introduced.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.6.0.0.

New Commands in ArubaOS 8.6.0.0

The following commands were introduced in ArubaOS 8.6.0.0:

Command	Description
<u>aaa user-del-req-timeout</u>	This command configures the user delete request timeout value.
<u>ap convert</u>	This command converts Campus APs or Remote APs to Instant APs.
<u>ipv6 nexthop-list</u>	This command configures a next-hop list for IPv6 address in policy-based routing.
<u>policy-domain</u>	This command configures a policy domain profile to apply role-based ACL for users present in different controllers.
<u>replace-config-reboot</u>	This command replaces the configuration in a stand-alone controller and the controller will reboot with provided configuration file.
<u>secondary masteripv6/secondary conductoripv6</u>	This command adds a secondary Mobility Master containing IPv6 address.
<u>show aaa user-delete-result</u>	This command displays the list of users deleted for the last twenty delete requests issued from the managed devices.
<u>show ap power-mgmt-statistics</u>	This command shows the power status statistics of an AP connected to a managed device.
<u>show ipv6 nexthop-list</u>	This command displays the next-hop list settings for IPv6 address in policy-based routing.
<u>show policy-domain group-profile</u>	This command displays the details of the policy domain group profile.
<u>show ucc custom-sip</u>	This command displays the custom SIP ALG configuration.
<u>show ucc webrtc</u>	This command displays the WebRTC ALG configuration.
<u>vpn-acl</u>	This command configures both session and route ACL for branch-vpnc tunnel traffic.

Modified Commands in ArubaOS 8.6.0.0

The following commands were modified in ArubaOS 8.6.0.0:

Command	Description
aaa user delete	This command can now be executed from the Mobility Master using the ip-addr<ip-addr> and macaddr <macaddr> parameters.
airmatch ap	The values, 5GHzu for upper-band radios and 5GHzi for lower-band radios are supported by AP-555 access points.
ap mesh-ht-ssid-profile	The high-efficiency-enable parameter is introduced.
ap packet-capture	Radio ID 2 is introduced for AP-555 access points.
ap system-profile	The command is modified to include fast recovery mode on 530 Series and 550 Series APs. The sesimagotag-esl-servername parameter was added.
clear	The route-cache-v6 sub-parameter is introduced to the datapath parameter.
est	The following parameters are introduced, <ul style="list-style-type: none"> ▪ Arbitrary label enrollment ▪ Arbitrary label re-enrollment ▪ Organizational unit name ▪ Username /password
ids dos-profile	The spoofed death blacklist parameter is removed.
iot transportProfile	The following parameters are introduced: <ul style="list-style-type: none"> ▪ deviceCountOnly ▪ proxy ▪ rtIsDestMAC ▪ vendorFilter The following deviceClassFilters are introduced: <ul style="list-style-type: none"> ▪ abilitySmartSensor ▪ mysphera ▪ sbeacon ▪ wifi-assoc-sta

Command	Description
	<ul style="list-style-type: none"> ▪ wifi-tags ▪ wifi-unassoc-sta
ip access-list route	<p>The following configuration options are included under ipv6 parameter:</p> <ul style="list-style-type: none"> ▪ any ▪ host <ip-addr> ▪ network<ip-addr><netmask> ▪ route next-hop-list <next-hop-list-name>
license	<p>The <ipv6-addr> sub-parameter is added to the server-ip parameter.</p>
masteripv6/conductoripv6	<p>The following parameters are introduced:</p> <ul style="list-style-type: none"> ▪ vpn-ipv6 <vpnipv6> ▪ peer-mac-1 <peermac-1> ▪ peer-mac-2 <peermac-2>
master-l3redundancy/conductor-l3redundancy	<p>The ipv6 <ipv6-addr> parameter is introduced.</p>
master-redundancy master-vrrp/conductor-redundancy conductor-vrrp	<p>The ipv6 <ipv6-addr> parameter is introduced.</p>
master-redundancy peer-ip-address/conductor-redundancy peer-ip-address	<p>The ipv6 <ipv6-addr> parameter is introduced.</p>
rf ht-radio-profile	<p>The bss-color-switch-count parameter is added.</p>
show airmatch debug apinfo	<p>The output parameters AP in Tri-Radio Mode and AP Tri-Radio Mode Last UpdTime are introduced for AP-555 access points.</p>
show airmatch debug nbr	<p>The output displays information about Radio 2 for AP-555 access points.</p>
show airmatch debug reporting-radio	<p>The output for AP-555 access points will display 5GHz Client count.</p>
show airmatch event	<p>The output displays information about Radio 2 for AP-555 access points.</p>
show airmatch solution	<p>The output displays information about Radio 2 for AP-555 access points.</p>

Command	Description
show ap active	The output parameter Radio 2 Band Ch/EIRP/MaxEIRP/Clients and flag t are introduced.
show ap arm client-match summary	The output of show ap arm client-match summary advanced will display the percentage of ClientMatch success in addition to the absolute values.
show ap arm client-match restriction-table	The output will display Client Restriction Table for Wifi2 for AP-555 access points.
show ap arm rf-summary	The output will display an interface report for Radio 2 for AP-555 access points.
show ap arm split-scan-history	The output will display an interface for Radio 2 for AP-555 access points.
show ap arm virtual-beacon-report	The output will display an interface report for Radio 2 for AP-555 access points.
show ap association	The output of this command is modified to include new flags for MBO and CDC feature for 802.11ax capable APs.
show ap bss-table	The output of this command is modified to include new flags for MBO and CDC feature for 802.11ax capable APs.
show ap bw-report	The output parameter Bandwidth report for AP "AP-Name" radio 2 is introduced for AP-555 access points.
show ap config	The output parameter 802.11a- secondary is introduced for AP-555 access points.
show ap debug airmatch	A new interface for Radio 2 will be displayed for AP-555 access points.
show ap debug anyspot-stats	Radio ID 2 is introduced for AP-555 access points.

Command	Description
<u>show ap debug power-table</u>	Radio ID 2 is introduced for AP-555 access points.
<u>show ap debug radio-info</u>	Radio ID 2 is introduced for AP-555 access points.
<u>show ap debug radio-registers</u>	Radio ID 2 is introduced for AP-555 access points
<u>show ap debug radio-stats</u>	Radio ID 2 is introduced for AP-555 access points.
<u>show ap debug received-config</u>	The output will display details of Radio 2 for AP-555 access points.
<u>show ap debug scan-settings</u>	The output will display the status of Radio 2 for AP-555 access points.
<u>show ap monitor</u>	<p>A new interface for Radio 2 will be displayed for the following parameters,</p> <ul style="list-style-type: none"> ▪ show ap monitor containment-info ▪ show ap monitor debug ▪ show ap monitor scan-info <p>The output of this command is modified to display bss color related information:</p> <ul style="list-style-type: none"> ▪ bss-color ▪ partial bss color ▪ bss color disabled
<u>show ap details</u>	The output parameter Radio 2 BSSID is introduced.
<u>show ap profile-usage</u>	The output will display the list of profiles associated to Radio 2 in AP-555 access points.
<u>show ap radio-database</u>	The output parameter Radio 2 Band Ch/EIRP/MaxEIRP/Clients is introduced.
<u>show ap remote debug bucketmap datapath</u>	The output will display tri-radio values for AP-555 access points.
<u>show ap spectrum debug</u>	The parameter radio {0 1 2} is introduced.

Command	Description
show ap spectrum debug monitors	The output displays the details of Radio 0, 1 and 2 for AP-555 access points.
show ap spectrum device-duty-cycle	The parameter radio {0 1 2} is introduced.
show ap standby	The output parameter Radio 2 Band Ch/EIRP/MaxEIRP/Clients and flag t are introduced.
show ap uac-database	The output parameter Radio 2 BSSID is introduced.
show database	The output of this command is modified to include IPv6 address of the peer Mobility Master in Layer-2 and Layer-3 redundancy.
show datapath	The remote-user table parameter is introduced.
show est profile	<p>The following parameters are introduced,</p> <ul style="list-style-type: none"> ▪ Arbitrary label enrollment ▪ Arbitrary label re-enrollment ▪ Organizational unit name ▪ Username /password <p>The following changes are introduced:</p> <ul style="list-style-type: none"> ▪ The ipv6 option is added to the nexthop-list sub-parameter. ▪ The output of the show datapath session ipv6 command is modified to display the next-hop list details, and includes the NhIdx, Nhidx, and NhNhVer columns. ▪ The output of the show datapath ipsec-map command is modified to display v6 value under IP ver column.
show threshold-limits	The no-of-vaps parameter is introduced to display the details of Virtual APs.

Command	Description
show gsm debug	The remote_ip_user parameter is introduced.
show iot transportProfile	The Vendor Filter , IoT Proxy Server , IoT Proxy User , Send device counts only , and RTLS Destination MAC Address parameters are introduced.
show license aggregate	The output displays IPv6 address under IP address parameter.
show license debug	The output displays the following new parameters: <ul style="list-style-type: none"> ▪ Master IPv6 ▪ Switch IPv6
show license heartbeat stats	The output displays IPv6 address under IP address parameter.
show license-usage	The output displays IPv6 address under IP address parameter.
show rf ht-radio-profile	The following output parameters are added: <ul style="list-style-type: none"> ▪ BSS Color ▪ BSS Color Switch Count
threshold	The no-of-vaps<value> parameter is introduced.
ucc	The custom-sip and webrtc parameters are introduced.
wlan ssid-profile	The cdc-enable and mbo-enable parameters are introduced.
wlan he-ssid-profile	The command is modified to support OFDMA, MU-MIMO, and TWT on all 802.11ax capable APs.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.5.0.0.

New Commands in ArubaOS 8.5.0.0

The following commands were introduced in ArubaOS 8.5.0.0:

Command	Description
<u>ap wifi-uplink-profile</u>	This command is introduced to configure a Wi-Fi uplink profile.
<u>controller-ble opmode</u>	This command is introduced to configure BLE opmode in controller.
<u>show ap debug ble-action-status</u>	This command is introduced to display action status for BLE devices seen by the AP.
<u>show ap wifi-uplink blacklist</u>	This command is introduced to display a list of Wi-Fi uplink APs that have been denied access.
<u>show ap wifi-uplink candidates</u>	This command is introduced to display a list of Wi-Fi uplink candidate APs.
<u>show ap wifi-uplink connection-history</u>	This command is introduced to display the connection history of APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink connection-trace</u>	This command is introduced to display the connection trace of APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink current-profile</u>	This command is introduced to display the current profile information of APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink debug</u>	This command is introduced to display the debug information of APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink neighbors</u>	This command is introduced to display the information of neighboring APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink-profile</u>	This command is introduced to display a list of all Wi-Fi uplink profiles, or display the configuration parameters in a specific Wi-Fi uplink profile.
<u>show ap wifi-uplink provisioned-profiles</u>	This command is introduced to display information of provisioned profiles of APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink stats</u>	This command is introduced to display the statistics of APs with Wi-Fi uplink enabled.
<u>show ap wifi-uplink status</u>	This command is introduced to display the status of various parameters of APs with Wi-Fi uplink enabled.

Modified Commands in ArubaOS 8.5.0.0

The following commands were modified in ArubaOS 8.5.0.0:

Command	Description
aaa profile	The rfc-3576-server <ipaddr> parameter is updated to also support IPv6 address of the server.
aaa rfc-3576-server	The <ipaddr> sub-parameter is updated to also support IPv6 address of the server.
ap-group	The wifi-uplink-profile and enet0-usb-port-profile parameters are introduced.
ap system-profile	The rap-corp-dns-server and rap-corp-dns-server_ipv6 <ipv6 address> parameters are introduced.
crypto isakmp	The eap-gtc sub-parameter is introduced under the eap-passthrough parameter.
ids general-profile	The default value of max-monitored-devices parameter is modified to include both 1024 and 4096.
iot transportProfile	The aruba-sensors sub-parameter is introduced under the deviceClassFilter parameter.
interface tunnel	The keepalive icmp <ipaddr> <next-hop> parameter is introduced.
lc-cluster group-profile	The parameters, vrrp-id <starting id> and vrrp-passphrase <vrrp passphrase string> were added.
provision-ap	The link-priority-wifi and wifi-uplink parameters are introduced.
rf arm-profile	The cm-he-min-signal parameter is introduced.
rf am-scan-profile	The dwell-time-dos-channel parameter is introduced.
show ap active	A new flag, 4 is introduced to indicate Wi-Fi uplink.
show ap database	A new flag, 4 is introduced to indicate Wi-Fi uplink.
show ap-group	The Ethernet usb port configuration parameter is introduced.
show iot transportProfile	The aruba-sensors sub-parameter is introduced under the Device Class Filter parameter.
show lc-cluster	The load balance thresholds are updated and the Starting VRRP ID and VRRP Passphrase fields are added in the output.

Command	Description
show memory	The wcd sub-parameter is introduced under the ap parameter.
show wlan ssid-profile	The wpa3-aes-gcm-256 sub-parameter under the encryption parameter is introduced.
wlan ssid-profile	The refresh-direction parameter and the wpa3-aes-ccm-256 sub-parameter under the opmode parameter are introduced.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.4.0.0.

New Commands in ArubaOS 8.4.0.0

The following commands were introduced in ArubaOS 8.4.0.0:

Command	Description
ap ble-configure	This command is introduced to configure beacon attributes for a specific AP.
ap deep-sleep	This command is used to move the APs into deep-sleep mode.
ap provisioning-rule	This command is introduced to configure a group of APs and the subsequent actions to provision the APs.
ap provisioning-rules	This command is introduced to define the priority of the provisioning rules that are actively used by the Auto-provisioning feature in APs.
ap system-profile	The following parameters are added: <ul style="list-style-type: none">▪ <code>sesImagotag-esl-channel</code> - This parameter is introduced to configure the radio channel of SES-imagotag ESL system.▪ <code>sesImagotag-esl-serverip</code> - This parameter is introduced to configure the IP address of SES-imagotag ESL server.
ap wake-up	This command is used to wake up APs from the deep-sleep mode.
ap zeroize-tpm-keys	This command is introduced to erase the TPM content and render an AP permanently inoperable.
iapvpn-backward-compatible	This command is used to enable the older Instant APs to send register requests on the older HTTP port of 80.
iot radio-profile	This command is introduced to configure IoT radio profile.
ip domain redirect	This command is introduced to enable the DNS redirect feature.
ip domain-redirect	This command is introduced to redirect DNS query matching corporate domain to a dedicated corporate IPv4 DNS server.
ipv6 domain-redirect	This command is introduced to redirect the domain to a dedicated DNS server in the IPv6 domain.

Command	Description
<u>lc-cluster initiate schedule upgrade</u>	This command is introduced to schedule a cluster upgrade.
<u>lc-cluster initiate re-schedule upgrade</u>	This command is introduced to reschedule a scheduled cluster upgrade.
<u>lc-cluster initiate abort</u>	This command is introduced to delete or abort a scheduled cluster upgrade.
<u>password-recovery-disable</u>	This command is introduced to disable the default password recovery feature.
<u>password-recovery-user</u>	This command is introduced to create an alternate password recovery user.
<u>rf dot11-60GHz-radio-profile</u>	This command is introduced to configure AP radio settings for the 60 GHz frequency band, including the ARM profile for standalone controllers and the high-throughput (802.11ad) radio profile.
<u>show ap analytics recommendations</u>	This command is introduced to display the EIRP recommendations, channel-bandwidth recommendations, and regulatory domain profile recommendations to an AP.
<u>show ap ble-ibeacon-info</u>	This command displays the BLE ibeacon information for an AP.
<u>show ap debug esl-status</u>	This command displays the values for ESL Server, ESL Channel, ESL Radio, Configuration Status, and the ESL Dongle ID of an AP.
<u>show ap debug ses-esl-log</u>	This command displays the SES-Imagotog's ESL daemon debug logs for an AP.
<u>show ap greenap</u>	This command displays all the pending APs in the per-md list, sends the AP_INFO AMON message for a particular AP, and track Green AP related counters.
<u>show ap mesh debug link-table</u>	This command is introduced to display the mesh link table information for a remote mesh point or remote mesh portal.
<u>show ap provisioning-rule</u>	This command is introduced to display the information of an AP provisioning rule during Auto-provisioning..
<u>show ap provisioning-rules</u>	This command is introduced to display the information for the priority level of AP provisioning rules.
<u>show iot radio-profile</u>	This command displays the status of IoT radio profile.
<u>show provisioning-rule-info</u>	This command is introduced to display the information on each auto-provisioning rule and the associated APs.

Command	Description
show rf dot11-60GHz-radio-profile	This command displays an 802.11 60 GHz radio profile.
upgrade cancel-schedule	This command cancels an already scheduled upgrade of the managed devices.
upgrade reschedule	This command reschedules the existing scheduled upgrade of the managed devices.
vpn-peer pass-code	This command is introduced to configure authenticate code for automatic whitelisting of managed device on VPN Concentrators.
wlan he-ssid-profile	This command is introduced to configure a high-efficiency (802.11ax) SSID profile.
wmm-dscp-mapping	This command is introduced to enable the WMM DSCP map in the upstream direction of the decrypt-tunnel mode.
zeroize-tpm-keys	This command is introduced to erase the TPM content and render a controller permanently inoperable.

Modified Commands in ArubaOS 8.4.0.0

The following commands were modified in ArubaOS 8.4.0.0:

Command	Description
aaa authentication captive-portal	The ap-mac-in-redirect-url parameter is introduced.
aaa authentication via connection-profile	The I2-forwarding parameter is introduced.
ap-group	The dot11-60GHz-radio-profile parameter is introduced.
ap multizone-profile	<p>The following sub-parameters are introduced in the datazone parameter:</p> <ul style="list-style-type: none"> ▪ controller-ipv6 <ipv6> ▪ description <description> ▪ max-nodes <num_nodes> ▪ max-vaps <num_vaps> <p>The following sub-parameters are introduced in the primaryzone parameter:</p> <ul style="list-style-type: none"> ▪ max-nodes <num_nodes> ▪ max-vaps <num_vaps>

Command	Description
ap provisioning-profile	The apdot1x-tls-suffix , apdot1x-tls-suffix-domain , mesh-auto , and preferred_uplink parameters are introduced.
ap system-profile	<p>The following changes are introduced:</p> <ul style="list-style-type: none"> ■ The IPv6 address support is added to the ip-or-dns parameter. <p>The following parameters are introduced:</p> <ul style="list-style-type: none"> ■ ap-usb-power-mode ■ wids-ampdu-optimization ■ seslmagotag-esl-channel ■ seslmagotag-esl-serverip <p>The following parameters are introduced:</p> <ul style="list-style-type: none"> ■ radio_5ghz_chain_4x4 ■ radio_5ghz_chain_5x5 ■ radio_5ghz_chain_6x6 ■ radio_5ghz_chain_7x7
ap wired-ap-profile	The wired-ap-mode parameter is introduced.
banner	The enforce-accept parameter is introduced.
ble_relay	The export-ap-ble-ibeacon-info parameter introduced.
interface tunnel	The vlan {add <word>} {remove <word>} <word> sub-parameters are introduced to the trusted parameter.
interface vlan	The pppoe-gateway-nat <nat-ip> sub-parameter is introduced.
iot transportProfile	<p>The following server types were introduced:</p> <ul style="list-style-type: none"> ■ Assa-Abloy ■ Meridian-beacons-management ■ Meridian-asset-tracking ■ Telemetry-https ■ Telemetry-websocket ■ ZF-openmatics <p>The following deviceClassFilters were introduced:</p> <ul style="list-style-type: none"> ■ all ■ aruba-beacons

Command	Description
	<ul style="list-style-type: none"> ▪ aruba-tags ▪ assa-abloy ▪ eddystone ▪ enoccean-sensors ▪ enoccean-switches ▪ ibeacon ▪ unclassified ▪ zf-tags <p>The following parameters were renamed from:</p> <ul style="list-style-type: none"> ▪ endpointType to serverType ▪ endpointID to clientID ▪ endpointURL to serverURL ▪ endpointToken to accessToken ▪ transportInterval to reportingInterval ▪ payloadContent to deviceClassFilter ▪ filterAttribute to uuidFilter ▪ namespaceFilter to uidNamespaceFilter ▪ cellSize to cellSizeFilter ▪ thresholdAttribute to movementFilter ▪ outrangeAgeout to ageFilter
ip access-list session	The output displays the use of source NAT to route the local traffic in AP datapath in Split-Tunnel forwarding mode for IPv6 clients.
ip dhcp pool	The switch-gw-ip sub-parameter is introduced.
ipv6 dhcp pool	The switch-gw-ipv6 sub-parameter is introduced.
lc-cluster group-profile	The parameter rapcluster is added.
mgmt-user	<p>The following sub-parameters are introduced in the <username> parameter:</p> <ul style="list-style-type: none"> ▪ max-concurrent-sessions ▪ old-password <p>The audit-period parameter is introduced.</p>

Command	Description
provision-ap	The apdot1x-tls-suffix , apdot1x-tls-suffix-domain , mesh-auto , and preferred_uplink parameters are introduced.
rf dot11a-radio-profile	The high-efficiency-enable <radio> parameter is introduced.
rf dot11g-radio-profile	The high-efficiency-enable parameter is introduced.
rf ht-radio-profile	The bss-color parameter is introduced.
show airgroup aps	The output is modified to display the name of the neighbor AP, if available, in the Neighbor AP name parameter.
show aaa authentication via connection-profile	The output of this command is modified to display the Use I2 forwarding parameter.
show aaa radius-attributes	The output of this command is modified to display Aruba-Captive-Portal-URL VSA attribute.
show amon-sender	The following new parameters are added to support Smart AMON feature: <ul style="list-style-type: none"> ▪ bundle counters ▪ bundle parameters ▪ cdt message-type
show ap database	A new flag, p was introduced to show that the AP is in deep-sleep mode.
show ap debug multizone	The output of this command is modified to include V flags.
show ap details	The following changes are introduced: <ul style="list-style-type: none"> ▪ The output of the show ap details advanced ip-addr <ip-addr> command is modified to display a new field, Reason for disconnect. ▪ The output of the show ap details advanced ap-name <ap-name> command is

Command	Description
	modified to display Eirp (max, min, offset) information.
show ap-group	The output of this command is modified to display the 802.11 60GHz radio profile parameter and its corresponding value.
show ap mesh debug forwarding-table	The ssid parameter was introduced.
show ap monitor debug	The following changes are introduced: <ul style="list-style-type: none"> ▪ The ip6-addr parameter is added. ▪ The output of the show ap monitor debug status command displays both IPv4 and IPv6 addresses. ▪ The output of the show ap monitor debug status command includes the new counters to differentiate the distribution of DATA, MGMT, CTRL, and AGGR packets.
show ap monitor stats	The output of the show ap monitor stats command is modified to display the additional debug counter information.
show ap multizone-profile	The output is modified to display the IPv6 Address and Description columns.
show ap provisioning-profile	The output is modified to include the following parameters: <ul style="list-style-type: none"> ▪ AP dot1x EAP-TLS username suffix ▪ AP dot1x EAP-TLS username suffix domain ▪ USB power mode
show ap system-profile	The following changes are introduced: <ul style="list-style-type: none"> ▪ The output of the show ap system-profile <profile-name> include USB

Command	Description
	<p>command displays the AP USB Power mode parameter.</p> <ul style="list-style-type: none"> ▪ The AeroScout RTLS Server and RTLS Server configuration output parameter of the show ap system-profile <profile-name> include RTLS command displays IPv6 address.
show audit-trail	The output displays international characters in the ESSID, in unicode format.
show datapath	<p>The following changes are introduced:</p> <ul style="list-style-type: none"> ▪ The output of the #show datapath tunnel ipv6 command was modified to include B, G, and Y flags. ▪ The outputs of the show datapath route ap-name <ap-name> ipv6 and show datapath route-cache ap-name <ap-name> ipv6 commands are modified to display IPv6 route entries. ▪ The web-cc and counters sub-parameters are added to ipv6 parameter. ▪ The output of the show datapath session ipv6 web-cc command is modified to display WebCC related entries for IPv6 sessions. ▪ The trusted-vlan and untrusted-vlan sub-parameters are introduced in the show datapath tunnel tunnel-id <id> command.
show gsm debug	The via_user and rap-pubic-ip sub-parameter is introduced in the <channel> parameter.

Command	Description
show lc-cluster	This scheduled-upgrades and rap-public-ip parameter is introduced.
show license-usage	The Active MUX and Active PUTN parameters were added.
show mgmt-user	The following parameters are introduced: <ul style="list-style-type: none"> ▪ audit-info ▪ console The Max-concurrent-sessions parameter is introduced in the output.
show provisioning-params	The output is modified to include the following parameters: <ul style="list-style-type: none"> ▪ AP dot1x EAP-TLS username suffix ▪ AP dot1x EAP-TLS username suffix domain
show rights	The output displays the IPv6 ACE entries of role-based ACL in Split-Tunnel forwarding mode.
show tpm	The errorlog parameter is introduced.
show via	The lastlogin parameter is introduced.
show interface tunnel	The trusted-vlan and untrusted-vlan sub-parameters are introduced.
show ip pppoe-info	The output of the show ip pppoe-info command is modified to display Gateway NAT and IP parameters.
show sapm cluster nodestate	The Public IP address output column was added.
show web-cc	The output of the show webcc-status command displays the Connection mode for server parameter.
upgrade managed-devices	The schedule parameter is introduced.
webcc	The connectiontype ipv6 parameter is introduced.

Command	Description
wlan ssid-profile	The enhanced-open , wpa3-aes-ccm-128 , wpa3-cnsa , and wpa-sae-aes sub-parameters are introduced to the opmode parameter and the opmode-transition parameter is introduced.

Deprecated Commands in ArubaOS 8.4.0.0

The following commands were deprecated in ArubaOS 8.4.0.0:

Command	Description
panic	This command managed information created during a system crash.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.3.0.0.

New Commands in ArubaOS 8.3.0.0

The following commands were introduced in ArubaOS 8.3.0.0:

Command	Description
iot transportProfile	This command configures an IoT transport profile.
iot usetransportProfile	This command sets an IoT management server profile.
show iot transportProfile	This command displays information about the IoT profile status.
show airmatch debug apinfo	This command displays information about the AirMatch debug data of an AP.
show airmatch debug db-dump status	This command displays information about the status of the AirMatch debug database dump.
show airmatch debug pathloss history rep-radio	This command displays information about the recent AirMatch debug path loss.
show airmatch network-tech-support	This command collects the output for all the radios that are in the same partition for a specified radio AP name.
show airmatch tech-support	Displays the AirMatch technical support information of an AP.
show airmatch debug advanced stat	This command displays detailed information about the AirMatch debug status of an AP.
show ble_relay disp-attr	This command shows the BLE relay attributes.
show ble_relay iot-profile	This command shows the BLE relay IoT profile details.
show ble_relay tag-report	This command shows the BLE relay tag data.
show ble_relay ws-log	This command shows the BLE relay WebSocket logs.

Modified Commands in ArubaOS 8.3.0.0

The following commands were modified in ArubaOS 8.3.0.0:

Command	Description
aaa authentication via connection-profile	The following changes are introduced: <ul style="list-style-type: none">▪ A new parameter, tos-dscp, is introduced to support IPsec packets with higher QoS-DSCP.

Command	Description
	<ul style="list-style-type: none"> The description of the whitelist parameter is updated to display the maximum limit of allowable entries.
aaa profile	<p>The following new parameters are introduced:</p> <ul style="list-style-type: none"> radius-acct-session-id-in-access reauth-wired-user-vlan-change
ap system-profile	<p>The following new parameters are introduced:</p> <ul style="list-style-type: none"> dual-5ghz-mode recovery-mode
ap wired-port-profile	<p>The following new parameters are introduced:</p> <ul style="list-style-type: none"> auto-recovery-enable auto-recovery-interval loop-detection-interval loop-protect-enable
configuration device	<p>The A7280 option is added under the device-model parameter.</p>
provision-ap	<p>The following parameters are introduced:</p> <ul style="list-style-type: none"> radio-0-5ghz-ant-gain radio-0-5ghz-ant-pol radio-1-5ghz-ant-gain radio-1-5ghz-ant-pol
show ap active	<p>The new flags, T, U, V, and W are introduced. In addition, the output parameters for this command are modified to show the radio ID (that is, Radio 0 and Radio 1), radio band, and the debug details such as APs' operation modes for the dual 5GHz mode settings.</p>
show ap arm client-match history	<p>A new output value, AS is introduced for the Signal output column.</p>
show ap arm client-match summary	<p>A new parameter, brief, is introduced to display brief statistical information of the output parameters.</p>
show ap details	<p>The output of the command is modified to include AP Fast Recovery statistics.</p>
show airmatch debug feasibility	<p>The following parameters are introduced in the output of this command:</p> <ul style="list-style-type: none"> Current Opmode HW Supported Opmodes Configured Opmodes Feasible Opmodes

Command	Description
	<ul style="list-style-type: none"> ▪ Config BW range(MHz) ▪ Hardware BW range(MHz) ▪ Eirp Range Chan 20MHz ▪ Eirp Range Chan 40MHz ▪ Eirp Range Chan 80MHz ▪ Eirp Range Chan 160MHz ▪ Config EIRP range(dBm) ▪ Hardware EIRP range(dBm) ▪ EIRP Offset(dB) ▪ Band ▪ Band Range
<u>show ap debug radio-stats</u>	The output of this command includes MCS bucket mapping information with channel width, number of spatial streams, and guard interval information of 802.11ac APs.
<u>show ap debug bss-stats</u>	
<u>show ap debug client-stats</u>	
<u>show ap wired-port-profile</u>	<p>The following parameters are introduced in the output of this command:</p> <ul style="list-style-type: none"> ▪ Loop Protect Enable ▪ Loop Detection Interval ▪ Loop Protect Auto Recovery Enable ▪ Loop Protect Auto Recovery Interval
<u>show datapath</u>	The current standby entries counter is added to the station parameter.
<u>ssh</u>	The disable-ciphers and disable-mac parameters have been introduced in this command to configure ciphers and MAC algorithms, respectively.
<u>show ssh</u>	The ssh disable-ciphers and ssh disable-mac parameters are introduced to the output of this show command.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.2.2.0.

New Commands in ArubaOS 8.2.2.0

The following commands were introduced in ArubaOS 8.2.2.0:

Command	Description
show airmatch debug advanced stat	This command displays detailed statistics about the APs or radios on a Mobility Master.
show airmatch debug db-dump status	This command displays information about the status of the AirMatch debug database dump.
show airmatch network-tech-support	This command collects the output for all the radios that are in the same partition for a specified radio AP name. This command also lists and describes the AP radios that will be handled further.
show airmatch tech-support	This command collects the output for the AP or the radio, of a series of related AirMatch commands.

Modified Commands in ArubaOS 8.2.2.0

The following commands were modified in ArubaOS 8.2.2.0:

Command	Description
banner	The enforce-accept parameter is introduced.
mgmt-user	The following sub-parameters are introduced in the <username> parameter: <ul style="list-style-type: none">▪ max-concurrent-sessions▪ old-password The audit-period parameter is introduced.
show mgmt-user	The following parameters are introduced: <ul style="list-style-type: none">▪ audit-info▪ console The Max-concurrent-sessions parameter is introduced in the output.
show tpm	The errorlog parameter is introduced.
show via	The lastlogin parameter is introduced.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.2.1.0.

New Commands in ArubaOS 8.2.1.0

The following commands were introduced in ArubaOS 8.2.1.0:

Command	Description
<u>show airmatch debug advanced stat</u>	This command displays detailed statistics about the APs or radios on a Mobility Master.
<u>show airmatch debug db-dump status</u>	This command displays information about the status of the AirMatch debug database dump.
<u>show airmatch tech-support</u>	This command collects the output for all the radios that are in the same partition for a specified radio AP name. This command also lists and describes the AP radios that will be handled further.
<u>show airmatch network-tech-support</u>	This command collects the output for the AP or the radio, of a series of related AirMatch commands.

Modified Commands in ArubaOS 8.2.1.0

The following commands were modified in ArubaOS 8.2.1.0:

Command	Description
<u>clear</u>	The web-cc parameter is introduced.
<u>ip dhcp pool</u>	Support for specifying option code with hex data string is introduced.
<u>ntp authentication-key</u>	The sha1 parameter is introduced.
<u>rf dot11a-radio-profile</u>	The 300 Series access points disregards the value configured for the cell-size-reduction parameter.
<u>rf dot11g-radio-profile</u>	The 300 Series access points disregards the value configured for the cell-size-reduction parameter.
<u>show ip ospf</u>	The Tx Err and Rx Err parameters are added to the output of the show ip ospf interface vlan command.
<u>show ip route</u>	The order of displaying the administrative distance and cost is changed to [AD/Cost] from [Cost/AD] in the command output.
<u>show netdestination</u>	The Destination ID parameter is added to the command output.
<u>show ntp authentication-keys</u>	The output of this command is modified to show the SHA1 key type and secret (in encoded format), when SHA1 authentication is configured.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.2.0.0.

New Commands in ArubaOS 8.2.0.0

The following commands were introduced in ArubaOS 8.2.0.0:

Command	Description
<u>airgroupprofile</u>	This command is used to configure an AirGroup profile.
<u>ap deploy-profile</u>	This command is used to enable and configure policies on the AP deploy profile. The AP deployment policy redirects the selected APs to the Instant discovery process, ensuring that the APs run only in controller-less mode.
<u>ap redeploy controller-less</u>	The command sets the AP preference role to controller-less. APs with the controller-less preference role bypass controller discovery and immediately initiate Instant discovery.
<u>configuration rename</u>	This command is used to rename a node path.
<u>est</u>	This command is used to configure an EST profile on the controller or the AP for certificate enrollment.
<u>est-activate</u>	This command is used to activate an EST profile configured on the controller or the AP.
<u>ip dhcp increase-lease-limit</u>	This command configures additional DHCP scope that is twice the user limit on specific controller (that is, 7005 controller, 7008 controller, and 7010 controller) platforms.
<u>ipv6 helper-address</u>	This command enables the slog_flash application.
<u>master-l3redundancy/conductor-l3redundancy</u>	This command is used to configure Layer-3 redundancy for a Mobility Master.
<u>secondary masterip/secondary conductorip</u>	This command is used to configure a secondary master-ip.
<u>show ap deploy-profile</u>	This command displays the policies configured and the status of the AP deploy profile.
<u>show est status</u>	This command displays the current status of the EST profile configured on the device and optionally provides details of the EST on the consolidated list of switches.
<u>show master-l3redundancy/show conductor-l3redundancy</u>	This command displays the current status of Layer-3-domain Mobility Master redundancy. (

Command	Description
show scp	This command shows the SCP server functionality status of the controller or managed device.
show uap-blacklist/show uap-denylist	This command displays the Unified AP (UAP) blacklist database entries.
show wired-blacklist-clients/show wired-denylist-clients	This command shows the blacklisted wired clients.
show wms rogue-ap list	This command shows the list of rogue APs in the WMS.
uap-blacklist / uap-denylist	This command allows you to create, modify, delete, or purge a blacklist database on the device.
webcc	This command changes the WebCC operational mode from the default centralized mode to distributed mode for the managed device. In distributed mode, the managed device contacts the cloud WebRoot server for URL lookup queries as opposed to the Mobility Master in the default centralized mode.

Modified Commands in ArubaOS 8.2.0.0

The following commands were modified in ArubaOS 8.2.0.0:

Command	Description
aaa authentication wired	The blacklist-time parameter is added.
aaa rfc-3576-server	Event-timestamp-required , replay-protection , and window-duration parameters are added.
aaa timers	The range of stats-timeout parameter is updated to 5-60 minutes.
airmatch ap	The eirp parameter supports the configuration of EIRP values in .1 dBm increments. EIRP values for 270 Series access points can be configured as a negative value.
ap provisioning-profile	The apdot1x-factory-cert and apdot1x-tls parameters are added.
ap system-profile	The following changes are introduced to the ipm power-reduction-step-priority parameter: <ul style="list-style-type: none"> ▪ The all sub-parameter is added to remove all IPM steps or priorities by executing a single command. ▪ The priority parameter is not required now to delete a single IPM step/priority. You only

Command	Description
	<p>need to provide the ipm-step.</p> <ul style="list-style-type: none"> The following new parameters are introduced: disable_pse, radio_2ghz_chain_1x1, radio_2ghz_chain_2x2, radio_2ghz_chain_3x3, radio_2ghz_power_3dB, radio_2ghz_power_6dB, radio_5ghz_chain_1x1, radio_5ghz_chain_2x2, radio_5ghz_chain_3x3.
configuration node	The move-to sub-parameter is introduced under the <node-path> parameter.
crypto-local ipsec-map	The enrolled-cert-auth parameter is added to enable enrolled certificate authentication for site-to-site tunnel.
interface cellular	Updated the new syntax as ip access-group session <name>
interface gigabitethernet	Updated the new syntax as ip access-group {in out session {vlan <vlanId>}} <name>
interface port-channel	<p>The following changes are introduced:</p> <ul style="list-style-type: none"> Updated the new syntax as ip access-group {in out session {vlan <vlanId>}} <name> A new sub parameter <WORD> is introduced under switchport trunk allowed parameter. You can specify none to remove all the VLANs from the list of allowed VLANs configured on the trunk port.
interface port-channel	Updated the new syntax as ip access-group {in out session {vlan <vlanId>}} <acl_name> .
interface tunnel	Updated the new syntax as ip access group in <acl-name> .
interface vlan	Updated the new syntax as ip access-group in <acl_name> .
ipv6 domain lookup	The lookup parameter is added.
ipv6 name-server	The domain server IPv6 address is added.
ipv6 mld	The max-members-per-group parameter is added.
logging	New system processes called vrrp and lagm are added to debug issues related to vrrp and lacp in GSM channels respectively.
provision-ap	The apdot1x-factory-cert and apdot1x-tls parameters are added.

Command	Description
rf dot11a-radio-profile	The following parameters only appear in the command-line interface of Mobility Master, and are not configurable via a standalone controller <ul style="list-style-type: none"> ▪ deploy-hour ▪ eirp-max ▪ eirp-min ▪ eirp-offset
rf dot11g-radio-profile	<ul style="list-style-type: none"> ▪ energy-detect-threshold ▪ max-channel-bandwidth <p>The following parameter is only available in the command-line interface of a standalone controller, and is not configurable via Mobility Master.</p> <ul style="list-style-type: none"> ▪ channel
service	The scp parameter is introduced. This parameter enables the scp server functionality on the controller or managed device.
show aaa bandwidth-contracts	The dynamic parameter is added.
show airmatch debug feasibility	The output in the EIRP field can display EIRP values in .1 dBm increments, and the Update Reason field can show if an AirMatch update was made due to a radio band change by an AP radio that supports both 1x1 dual radio mode and 2x2 single radio mode (flex-mode).
show airmatch debug history	The output in the EIRP fields of these commands can display EIRP values in .1 dBm increments.
show airmatch debug reporting-radio	
show ap system-profile	The output of the command has a new parameter, IPM Steps delete all .
show ip domain-name	The IPv6 domain lookup parameter is added.
show configuration	A new parameter, filtered , is added to show the configuration downgraded to other versions. That is, it shows the configurations that are removed from the merged configuration before sending to a device.
show datapath	A new parameter, netdest-id , is added to show the datapath ACL netdestination table for AP name, IP address of AP, or ID.
show gsm debug	The sectun parameter accepts IPv6 addresses.
show interface vlan	The IPv6 helper-address is displayed in the output.
show ip dhcp	The output of this command is modified to display a warning message if the configured DHCP lease limit exceeds the maximum user limit defined.

Command	Description
<u>show license client-table</u>	The output of these commands display information for VIA licenses introduced in ArubaOS 8.2.0.0.
<u>show license server-table</u>	
<u>show ucc call-info cdrs</u>	The Server (IP) parameter is added.
<u>show upgrade-profile</u>	The serveraddr parameter is added.
<u>show web-cc</u>	The output of this command is enhanced to display information for WebCC license features configured in centralized or distributed mode.
<u>upgrade managed-devices</u>	The imagehost parameter accepts IPv6 address of the image server.
<u>upgrade-profile</u>	The serveraddr parameter accepts IPv6 address of the image server.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.1.0.0.

New Commands in ArubaOS 8.1.0.0

The following commands were introduced in ArubaOS 8.1.0.0:

Command	Description
aaa radius modifier	This command configures the RADIUS modifier profile to customize the attributes that are included, excluded and modified in the RADIUS request before it is sent to the authentication server.
lb-group	This command manages and configures the load balancing group.
lc-cluster initiate initiate Upgrade	This command is used to upgrade a cluster.
show aaa radius modifier	This command displays all the RADIUS modifier profiles.
show airmatch optimization	This command displays list of recent RF optimization jobs performed by AirMatch, and displays statistics that determine the overall quality of the optimization change.
show running-config	This command displays the current Mobility Master configuration, including all pending changes that are yet to be saved.
show tunneled-node-mgr	This command displays the tunneled node configuration details, the state of the tunneled node, and lists all the tunneled nodes in the database.

Modified Commands in ArubaOS 8.1.0.0

The following commands were modified in ArubaOS 8.1.0.0:

Command	Description
aaa authentication-server radius	The acct-modifier and auth-modifier parameters are introduced.
aaa authentication via auth-profile	The client-cert-enable parameter is introduced.
aaa authentication via connection-profile	The certificate-criteria parameter is introduced.
aaa profile	The radius-roam-accounting parameter is introduced.
aaa test-server	The verbose option is introduced.
amon msg-buffer-size	The msg-buffer-size range is modified.
ap multizone-profile	The primaryzone parameter was introduced.

Command	Description
airmatch profile	The eirp-offset parameter is removed from this command. This parameter is introduced into the rf dot11a-radio-profile and rf dot11g-radio-profile commands to support greater flexibility in configuring EIRP levels.
crypto-local ipsec-map	The any sub-parameter is introduced in dst-net , and src-net parameters. . The client-mode , load-balance , and monitor parameters are introduced.
crypto ipsec	The esp-null transform-set parameter is introduced.
ipv6 proxy-ra	The proxy-ra parameter is modified to enable proxy router advertisements.
logging	The format parameter is introduced to allow cef or bsd-standard logging formats.
mgmt-server	The following changes were introduced: <ul style="list-style-type: none"> ▪ The primary-server parameter is modified to accept IPv6 address. ▪ The Clarity Live parameters such as inline-ap-stats, inline-auth-stats, inline-dhcp-stats, and inline-dns-stats are introduced. ▪ The secure and transport parameters are introduced to specify the use of DTLS mode.
mgmt-user	The standard role is introduced.
ntp	The server-mode and source parameters are introduced.
ping	The following parameters are introduced: <ul style="list-style-type: none"> ▪ interval ▪ ttl ▪ validate-reply
provision-ap	The server-ip parameter is modified to accept IPv6 address.
rf dot11a-radio-profile	The deploy-hour parameter is introduced to set the hour during which AirMatch updates are sent to the APs using that radio profile. If this parameter is set in both the AirMatch profile and the 5 GHz (802.11a) radio profile, the setting in the 5 GHz radio profile will take precedence. The eirp-offset parameter is introduced to modify EIRP levels selected by the AirMatch algorithm. The energy-detect-threshold parameter is introduced to modify the Energy Detect Threshold (EDT) used by the AP radio in making transmit decisions. The minimum-channel-bandwidth parameter is introduced to set the minimum channel bandwidth for 802.11a radios on APs associated to Mobility Master managed devices.

Command	Description
rf dot11g-radio-profile	<p>The deploy-hour parameter is introduced to set the hour during which AirMatch updates are sent to the APs using that radio profile. If this parameter is set in both the AirMatch profile and the 5 GHz (802.11a) radio profile, the setting in the 5 GHz radio profile will take precedence.</p> <p>The airp-offset parameter is introduced to modify EIRP levels selected by the AirMatch algorithm.</p> <p>The energy-detect-threshold parameter is introduced to modify the Energy Detect Threshold (EDT) used by the AP radio in making transmit decisions.</p> <p>The minimum-channel-bandwidth parameter is introduced to set the minimum channel bandwidth for 2.4 GHz (802.11g) radios on APs associated to Mobility Master or managed devices.</p>
router ospf	The static sub-parameter is introduced under the redistribute parameter.
show aaa profile	The RADIUS Roaming Accounting parameter is introduced.
show airmatch solution	The output of this command has been modified in ArubaOS 8.1. This command now displays history of AirMatch solution updates, including the previous and updated channel and EIRP values. The capacity , cost and conflict values that appeared in the output in previous versions of this command now appear in the output of the command show airmatch optimization .
show amon-sender	<p>The following parameters are modified to accept IPv6 address:</p> <ul style="list-style-type: none"> ▪ dest-stats-all ▪ dest-stats-inst-0-7 ▪ interest-table
show gsm debug	The tunneled_node and tunneled_user parameter are introduced.
show ipv6 ra	The proxy parameter is introduced.
show mgmt-servers	This command lists primary servers with IPv6 address.
uplink	The load-balance and wired parameters are introduced.
web-server profile	The via-client-cert-port parameter is introduced.

This section lists the commands introduced, modified, or deprecated in ArubaOS 8.0.1.0.

New Commands in ArubaOS 8.0.1.0

The following commands were introduced in ArubaOS 8.0.1.0:

Command	Description
airmatch db-dump	This command creates a dump of the database used by AirMatch. The dump file can be exported using the copy command.
crypto-local isakmp allow-via-subnet-routes	This command allows VIA clients to push subnet routes to Mobility Master.
papi-security	The papi-security command enforces advanced security options and provides an enhanced level of security. It allows to enable or disable the PAPI Enhanced Security configuration and to configure a new security key if required.
show ip-flow-export wireless-cache	The show ip-flow-export wireless-cache command displays the cache for WLAN information.
show papi-security	The show papi-security command shows a configured papi-security profile.
show websocket	The show websocket command displays the ClearPass WebSocket configuration.

Modified Commands in ArubaOS 8.0.1.0

The following commands were modified in ArubaOS 8.0.1.0:

Command	Description
airmatch ap	The lms lms-ip <lms-ip> and lms lms-ipv6 <lms-ipv6> parameters are introduced, to allow you to freeze or unfreeze AP channels on a local controller.
airmatch profile	The quality-threshold parameter is introduced, which allows you to select a percentage of potential channel improvement that will trigger a new channel solution.
airmatch db-dump	This command creates a dump of the database used by AirMatch. The dump file can be exported using the copy command.
ap multizone-profile	The num-nodes sub-parameter is introduced.
ip-flow-export-profile	The wireless-export parameter is introduced.
interface mgmt	vlan-tag optional sub-parameter is introduced under the ip address and ipv6 address parameters.

Command	Description
<u>logging</u>	The logging level <severity> is moved to the end of the command string.
<u>license</u>	The server-ip parameter is introduced to configure a standalone controller as a licensing client.
<u>mgmt-user</u>	The node parameter is introduced in the mgmt-user <username> <rolename> command.
<u>show ap multizone-profile</u>	The num-nodes sub-parameter is introduced.
<u>show crypto-local isakmp</u>	The allow-via-subnet-routes sub-command is introduced.
<u>show ipc statistics app-name</u>	Tx Sign, Rx Sign, and Rx Denied columns are added to the command output.
<u>show license-usage</u>	The verbose parameter is added to display license usage statistics for individual license pools and the devices associated to those license pools.

The following is the list of terminologies used in this guide.

3DES

Triple Data Encryption Standard. 3DES is a symmetric-key block cipher that applies the DES cipher algorithm three times to each data block.

3G

Third Generation of Wireless Mobile Telecommunications Technology. See W-CDMA.

3GPP

Third Generation Partnership Project. 3GPP is a collaborative project aimed at developing globally acceptable specifications for third generation mobile systems.

4G

Fourth Generation of Wireless Mobile Telecommunications Technology. See LTE.

802.11

802.11 is an evolving family of specifications for wireless LANs developed by a working group of the Institute of Electrical and Electronics Engineers (IEEE). 802.11 standards use the Ethernet protocol and Carrier Sense Multiple Access with collision avoidance (CSMA/CA) for path sharing.

802.11 bSec

802.11 bSec is an alternative to 802.11i. The difference between bSec and standard 802.11i is that bSec implements Suite B algorithms wherever possible. Notably, Advanced Encryption Standard-Counter with CBC-MAC is replaced by Advanced Encryption Standard - Galois/Counter Mode, and the Key Derivation Function (KDF) of 802.11i is upgraded to support SHA-256 and SHA-384.

802.11a

802.11a provides specifications for wireless systems. Networks using 802.11a operate at radio frequencies in the 5 GHz band. The specification uses a modulation scheme known as orthogonal frequency-division multiplexing (OFDM) that is especially well suited to use in office settings. The maximum data transfer rate is 54 Mbps.

802.11ac

802.11ac is a wireless networking standard in the 802.11 family that provides high-throughput WLANs on the 5 GHz band.

802.11b

802.11b is a WLAN standard often called Wi-Fi and is backward compatible with 802.11. Instead of the Phase-Shift Keying (PSK) modulation method used in 802.11 standards, 802.11b uses Complementary Code Keying (CCK) that allows higher data speeds and makes it less susceptible to multipath-propagation interference. 802.11b operates in the 2.4 GHz band and the maximum data transfer rate is 11 Mbps.

802.11d

802.11d is a wireless network communications specification for use in countries where systems using other standards in the 802.11 family are not allowed to operate. Configuration can be fine-tuned at the Media Access Control (MAC) layer level to comply with the rules of the country or district in which the network is to be used. Rules are subject to variation and include allowed frequencies, allowed power levels, and allowed signal bandwidth. 802.11d facilitates global roaming.

802.11e

802.11e is an enhancement to the 802.11a and 802.11b specifications that enhances the 802.11 Media Access Control layer with a coordinated Time Division Multiple Access (TDMA) construct. It adds error-correcting mechanisms for delay-sensitive applications such as voice and video. The 802.11e specification provides seamless interoperability between business, home, and public environments such as airports and hotels, and offers all subscribers high-speed Internet access with full-motion video, high-fidelity audio, and VoIP.

802.11g

802.11g offers transmission over relatively short distances at up to 54 Mbps, compared with the 11 Mbps theoretical maximum of 802.11b standard. 802.11g employs Orthogonal Frequency Division Multiplexing (OFDM), the modulation scheme used in 802.11a, to obtain higher data speed. Computers or terminals set up for 802.11g can fall back to speed of 11 Mbps, so that 802.11b and 802.11g devices can be compatible within a single network.

802.11h

802.11h is intended to resolve interference issues introduced by the use of 802.11a in some locations, particularly with military Radar systems and medical devices. Dynamic Frequency Selection (DFS) detects the presence of other devices on a channel and automatically switches the network to another channel if and when such signals are detected. Transmit Power Control (TPC) reduces the radio frequency (RF) output power of each network transmitter to a level that minimizes the risk of interference.

802.11i

802.11i provides improved encryption for networks that use 802.11a, 802.11b, and 802.11g standards. It requires new encryption key protocols, known as Temporal Key Integrity Protocol (TKIP) and Advanced Encryption Standard (AES).

802.11j

802.11j is a proposed addition to the 802.11 family of standards that incorporates Japanese regulatory extensions to 802.11a; the main intent is to add channels in the radio frequency (RF) band of 4.9 GHz to 5.0 GHz.

802.11k

802.11k is an IEEE standard that enables APs and client devices to discover the best available radio resources for seamless BSS transition in a WLAN.

802.11m

802.11m is an Initiative to perform editorial maintenance, corrections, improvements, clarifications, and interpretations relevant to documentation for 802.11 family specifications.

802.11n

802.11n is a wireless networking standard to improve network throughput over the two previous standards, 802.11a and 802.11g. With 802.11n, there will be a significant increase in the maximum raw data rate from 54 Mbps to 600 Mbps with the use of four spatial streams at a channel width of 40 MHz.

802.11r

802.11r is an IEEE standard for enabling seamless BSS transitions in a WLAN. 802.11r standard is also referred to as Fast BSS transition.

802.11u

802.11u is an amendment to the IEEE 802.11 WLAN standards for connection to external networks using common wireless devices such as smartphones and tablet PCs. The 802.11u protocol provides wireless clients with a streamlined mechanism to discover and authenticate to suitable networks, and allows mobile users to roam between partner networks without additional authentication. An 802.11u-capable device supports the Passpoint technology from the Wi-Fi Alliance Hotspot 2.0 R2 Specification that simplifies and automates access to public Wi-Fi.

802.11v

802.11v is an IEEE standard that allows client devices to exchange information about the network topology and RF environment. This information is used for assigning best available radio resources for the client devices to provide seamless connectivity.

802.1Q

802.1Q is an IEEE standard that enables the use of VLANs on an Ethernet network. 802.1Q supports VLAN tagging.

802.1X

802.1X is an IEEE standard for port-based network access control designed to enhance 802.11 WLAN security. 802.1X provides an authentication framework that allows a user to be authenticated by a central authority.

802.3af

802.3af is an IEEE standard for Power over Ethernet (PoE) version that supplies up to 15.4W of DC power. See PoE.

802.3at

802.3at is an IEEE standard for PoE version that supplies up to 25.5W of DC power. See PoE+.

A-MPDU

Aggregate MAC Protocol Data Unit. A-MPDU is a method of frame aggregation, where several MPDUs are combined into a single frame for transmission.

A-MSDU

Aggregate MAC Service Data Unit. A-MSDU is a structure containing multiple MSDUs, transported within a single (unfragmented) data MAC MPDU.

AAA

Authentication, Authorization, and Accounting. AAA is a security framework to authenticate users, authorize the type of access based on user credentials, and record authentication events and information about the network access and network resource consumption.

ABR

Area Border Router. ABR is used for establishing connection between the backbone networks and the Open Shortest Path First (OSPF) areas. ABR is located near the border of one or more OSPF areas.

AC

Access Category. As per the IEEE 802.11e standards, AC refers to various levels of traffic prioritization in Enhanced Distributed Channel Access (EDCA) operation mode. The WLAN applications prioritize traffic based on the Background, Best Effort, Video, and Voice access categories. AC can also refer to Alternating Current, a form of electric energy that flows when the appliances are plugged to a wall socket.

ACC

Advanced Cellular Coexistence. The ACC feature in APs enable WLANs to perform at peak efficiency by minimizing interference from 3G/4G/LTE networks, distributed antenna systems, and commercial small cell/femtocell equipment.

Access-Accept

Response from the RADIUS server indicating successful authentication and containing authorization information.

Access-Reject

Response from RADIUS server indicating that a user is not authorized.

Access-Request

RADIUS packet sent to a RADIUS server requesting authorization.

Accounting-Request

RADIUS packet type sent to a RADIUS server containing accounting summary information.

Accounting-Response

RADIUS packet sent by the RADIUS server to acknowledge receipt of an Accounting-Request.

ACE

Access Control Entry. ACE is an element in an ACL that includes access control information.

ACI

Adjacent Channel Interference. ACI refers to interference or interruptions detected on a broadcasting channel, caused by too much power on an adjacent channel in the spectrum.

ACL

Access Control List. ACL is a common way of restricting certain types of traffic on a physical port.

Active Directory

Microsoft Active Directory. The directory server that stores information about a variety of things, such as organizations, sites, systems, users, shares, and other network objects or components. It also provides authentication and authorization mechanisms, and a framework within which related services can be deployed.

ActiveSync

Mobile data synchronization app developed by Microsoft that allows a mobile device to be synchronized with either a desktop or a server running compatible software products.

ad hoc network

An ad hoc network is a network composed of individual devices communicating with each other directly. Many ad hoc networks are Local Area Networks (LANs) where computers or other devices are enabled to send data directly to one another rather than going through a centralized access point.

ADO

Active X Data Objects is a part of Microsoft Data Access Components (MDACs) that enables client applications to access data sources through an (Object Linking and Embedding Database) OLE DB provider. ADO supports key features for building client-server and Web-based applications.

ADP

Aruba Discovery Protocol. ADP is an Aruba proprietary Layer 2 protocol. It is used by the APs to obtain the IP address of the TFTP server from which it downloads the AP boot image.

AES

Advanced Encryption Standard. AES is an encryption standard used for encrypting and protecting electronic data. The AES encrypts and decrypts data in blocks of 128 bits (16 bytes), and can use keys of 128 bits, 192 bits, and 256 bits.

AIFSN

Arbitrary Inter-frame Space Number. AIFSN is set by the AP in beacon frames and probe responses. AIFS is a method of prioritizing a particular category of traffic over the other, for example prioritizing voice or video messages over email.

AirGroup

The application that allows the end users to register their personal mobile devices on a local network and define a group of friends or associates who are allowed to share them. AirGroup is primarily designed for colleges and other institutions. AirGroup uses zero configuration networking to allow Apple mobile devices, such as the AirPrint wireless printer service and the AirPlay mirroring service, to communicate over a complex access network topology.

AirWave Management Client

AirWave Management Client is a Windows software utility that enables client devices (such as a laptop) to act as passive RF sensors and augments the AirWave RAPIDS module.

ALE

Analytics and Location Engine. ALE gives visibility into everything the wireless network knows. This enables customers and partners to gain a wealth of information about the people on their premises.

This can be very important for many different verticals and use cases. ALE includes a location engine that calculates associated and unassociated device location periodically using context streams, including RSSI readings, from WLAN controllers or Instant clusters.

ALG

Application Layer Gateway. ALG is a security component that manages application layer protocols such as SIP, FTP and so on.

AM

Air Monitor. AM is a mode of operation supported on wireless APs. When an AP operates in the Air Monitor mode, it enhances the wireless networks by collecting statistics, monitoring traffic, detecting intrusions, enforcing security policies, balancing wireless traffic load, self-healing coverage gaps, and more. However, clients cannot connect to APs operating in the AM mode.

AMON

Advanced Monitoring. AMON is used in Aruba WLAN deployments for improved network management, monitoring and diagnostic capabilities.

AMP

AirWave Management Platform. AMP is a network management system for configuring, monitoring, and upgrading wired and wireless devices on your network.

ANQP

Access Network Query Protocol. ANQP is a query and a response protocol for Wi-Fi hotspot services. ANQP includes information Elements (IEs) that can be sent from the AP to the client to identify the AP network and service provider. The IEs typically include information about the domain name of the AP operator, the IP addresses available at the AP, and information about potential roaming partners accessible through the AP. If the client responds with a request for a specific IE, the AP will send a Generic Advertisement Service (GAS) response frame with the configured ANQP IE information.

ANSI

American National Standards Institute. It refers to the ANSI compliance standards for products, systems, services, and processes.

API

Application Programming Interface. Refers to a set of functions, procedures, protocols, and tools that enable users to build application software.

app

Short form for application. It generally refers to the application that is downloaded and used on mobile devices.

ARM

Adaptive Radio Management. ARM dynamically monitors and adjusts the network to ensure that all users are allowed ready access. It enables full utilization of the available spectrum to support maximum number of users by intelligently choosing the best RF channel and transmit power for APs in their current RF environment.

ARP

Address Resolution Protocol. ARP is used for mapping IP network address to the hardware MAC address of a device.

Aruba Activate

Aruba Activate is a cloud-based service that helps provision your Aruba devices and maintain your inventory. Activate automates the provisioning process, allowing a single IT technician to easily and rapidly deploy devices throughout a distributed enterprise network.

ASCII

American Standard Code for Information Interchange. An ASCII code is a numerical representation of a character or an action.

B-RAS

Broadband Remote Access Server. A B-RAS is a server that facilitates and converges traffic from multiple Internet traffic resources such as cable, DSL, Ethernet, or Broadband wireless.

band

Band refers to a specified range of frequencies of electromagnetic radiation.

BGP

Border Gateway Protocol. BGP is a routing protocol for exchanging data and information between different host gateways or autonomous systems on the Internet.

BLE

Bluetooth Low Energy. The BLE functionality is offered by Bluetooth® to enable devices to run for long durations with low power consumption.

BMC

Beacon Management Console. BMC manages and monitors beacons from the BLE devices. The BLE devices are used for location tracking and proximity detection.

BPDU

Bridge Protocol Data Unit. A BPDU is a data message transmitted across a local area network to detect loops in network topologies.

BRE

Basic Regular Expression. The BRE syntax standards designed by the IEEE provides extension to the traditional Simple Regular Expressions syntax and allows consistency between utility programs such as grep, sed, and awk.

BSS

Basic Service Set. A BSS is a set of interconnected stations that can communicate with each other. BSS can be an independent BSS or infrastructure BSS. An independent BSS is an ad hoc network that does not include APs, whereas the infrastructure BSS consists of an AP and all its associated clients.

BSSID

Basic Service Set Identifier. The BSSID identifies a particular BSS within an area. In infrastructure BSS networks, the BSSID is the MAC address of the AP. In independent BSS or ad hoc networks, the BSSID

is generated randomly.

BYOD

Bring Your Own Device. BYOD refers to the use of personal mobile devices within an enterprise network infrastructure.

CA

Certificate Authority or Certification Authority. Entity in a public key infrastructure system that issues certificates to clients. A certificate signing request received by the CA is converted into a certificate when the CA adds a signature generated with a private key. See digital certificate.

CAC

Call Admission Control. CAC regulates traffic volume in voice communications. CAC can also be used to ensure or maintain a certain level of audio quality in voice communications networks.

CALEA

Communications Assistance for Law Enforcement Act. To comply with the CALEA specifications and to allow lawful interception of Internet traffic by the law enforcement and intelligence agencies, the telecommunications carriers and manufacturers of telecommunications equipment are required to modify and design their equipment, facilities, and services to ensure that they have built-in surveillance capabilities.

Campus AP

Campus APs are used in private networks where APs connect over private links (LAN, WLAN, WAN or MPLS) and terminate directly on controllers. Campus APs are deployed as part of the indoor campus solution in enterprise office buildings, warehouses, hospitals, universities, and so on.

captive portal

A captive portal is a web page that allows the users to authenticate and sign in before connecting to a public-access network. Captive portals are typically used by business centers, airports, hotel lobbies, coffee shops, and other venues that offer free Wi-Fi hotspots for the guest users.

CCA

Clear Channel Assessment. In wireless networks, the CCA method detects if a channel is occupied or clear, and determines if the channel is available for data transmission.

CDP

Cisco Discovery Protocol. CDP is a proprietary Data Link Layer protocol developed by Cisco Systems. CDP runs on Cisco devices and enables networking applications to learn about the neighboring devices directly connected to the network.

CDR

Call Detail Record. A CDR contains the details of a telephone or VoIP call, such as the origin and destination addresses of the call, the start time and end time of the call, any toll charges that were added through the network or charges for operator services, and so on.

CEF

Common Event Format. The CEF is a standard for the interoperability of event or log-generating devices and applications. The standard syntax for CEF includes a prefix and a variable extension

formatted as key-value pairs.

CGI

Common Gateway Interface. CGI is a standard protocol for exchanging data between the web servers and executable programs running on a server to dynamically process web pages.

CHAP

Challenge Handshake Authentication Protocol. CHAP is an authentication scheme used by PPP servers to validate the identity of remote clients.

CIDR

Classless Inter-Domain Routing. CIDR is an IP standard for creating and allocating unique identifiers for networks and devices. The CIDR IP addressing scheme is used as a replacement for the older IP addressing scheme based on classes A, B, and C. With CIDR, a single IP address can be used to designate many unique IP addresses. A CIDR IP address ends with a slash followed by the IP network prefix, for example, 192.0.2.0/24.

ClearPass

ClearPass is an access management system for creating and enforcing policies across a network to all devices and applications. The ClearPass integrated platform includes applications such as Policy Manager, Guest, Onboard, OnGuard, Insight, Profile, QuickConnect, and so on.

ClearPass Guest

ClearPass Guest is a configurable ClearPass application for secure visitor network access management.

ClearPass Policy Manager

ClearPass Policy Manager is a baseline platform for policy management, AAA, profiling, network access control, and reporting. With ClearPass Policy Manager, the network administrators can configure and manage secure network access that accommodates requirements across multiple locations and multivendor networks, regardless of device ownership and connection method.

CLI

Command-Line Interface. A console interface with a command line shell that allows users to execute text input as commands and convert these commands to appropriate functions.

CN

Common Name. CN is the primary name used to identify a certificate.

CNA

Captive Network Assistant. CNA is a popup page shown when joining a network that has a captive portal.

CoA

Change of Authorization. The RADIUS CoA is used in the AAA service framework to allow dynamic modification of the authenticated, authorized, and active subscriber sessions.

CoS

Class of Service. CoS is used in data and voice protocols for classifying packets into different types of traffic (voice, video, or data) and setting a service priority. For example, voice traffic can be assigned a higher priority over email or HTTP traffic.

CPE

Customer Premises Equipment. It refers to any terminal or equipment located at the customer premises.

CPsec

Control Plane Security. CPsec is a secure form of communication between a controller and APs to protect the control plane communications. This is performed by means of using public-key self-signed certificates created by each master controller.

CPU

Central Processing Unit. A CPU is an electronic circuitry in a computer for processing instructions.

CRC

Cyclic Redundancy Check. CRC is a data verification method for detecting errors in digital data during transmission, storage, or retrieval.

CRL

Certificate Revocation List. CRL is a list of revoked certificates maintained by a certification authority.

cryptobinding

Short for cryptographic binding. A procedure in a tunneled EAP method that binds together the tunnel protocol and the tunneled authentication methods, ensuring the relationship between a collection of data assets. Cryptographic binding focuses on protecting the server; mutual cryptographic binding protects both peer and server.

CSA

Channel Switch Announcement. The CSA element enables an AP to advertise that it is switching to a new channel before it begins transmitting on that channel. This allows the clients, which support CSA, to transition to the new channel with minimal downtime.

CSMA/CA

Carrier Sense Multiple Access / Collision Avoidance. CSMA/CA is a protocol for carrier transmission in networks using the 802.11 standard. CSMA/CA aims to prevent collisions by listening to the broadcasting nodes, and informing devices not to transmit any data until the broadcasting channel is free.

CSR

Certificate Signing Request. In PKI systems, a CSR is a message sent from an applicant to a CA to apply for a digital identity certificate.

CSV

Comma-Separated Values. A file format that stores tabular data in the plain text format separated by commas.

CTS

Clear to Send. The CTS refers to the data transmission and protection mechanism used by the 802.11 wireless networking protocol to prevent frame collision occurrences. See RTS.

CW

Contention Window. In QoS, CW refers to a window set for access categories based on the type of traffic. Based on the type and volume of the traffic, the minimum and maximum values can be calculated to provide a wider window when necessary.

DAI

Dynamic ARP inspection. A security feature that validates ARP packets in a network.

DAS

Distributed Antenna System. DAS is a network of antenna nodes strategically placed around a geographical area or structure for additional cellular coverage.

dB

Decibel. Unit of measure for sound or noise and is the difference or ratio between two signal levels.

dBm

Decibel-Milliwatts. dBm is a logarithmic measurement (integer) that is typically used in place of mW to represent receive-power level. AMP normalizes all signals to dBm, so that it is easy to evaluate performance between various vendors.

DCB

Data Center Bridging. DCB is a collection of standards developed by IEEE for creating a converged data center network using Ethernet.

DCE

Data Communication Equipment. DCE refers to the devices that establish, maintain, and terminate communication network sessions between a data source and its destination.

DCF

Distributed Coordination Function. DCF is a protocol that uses carrier sensing along with a four-way handshake to maximize the throughput while preventing packet collisions.

DDMO

Distributed Dynamic Multicast Optimization. DDMO is similar to Dynamic Multicast Optimization (DMO) where the multicast streams are converted into unicast streams on the AP instead of the controller, to enhance the quality and reliability of streaming videos, while preserving the bandwidth available to non-video clients.

DES

Data Encryption Standard. DES is a common standard for data encryption and a form of secret key cryptography, which uses only one key for encryption and decryption.

designated router

Designated router refers to a router interface that is elected to originate network link advertisements for networks using the OSPF protocol.

destination NAT

Destination Network Address Translation. Destination NAT is a process of translating the destination IP address of an end route packet in a network. Destination NAT is used for redirecting the traffic destined to a virtual host to the real host, where the virtual host is identified by the destination IP address and the real host is identified by the translated IP address.

DFS

Dynamic Frequency Selection. DFS is a mandate for radio systems operating in the 5 GHz band to be equipped with means to identify and avoid interference with Radar systems.

DFT

Discrete Fourier Transform. DFT converts discrete-time data sets into a discrete-frequency representation. See FFT.

DHCP

Dynamic Host Configuration Protocol. A network protocol that enables a server to automatically assign an IP address to an IP-enabled device from a defined range of numbers configured for a given network.

DHCP snooping

DHCP snooping enables the switch to monitor and control DHCP messages received from untrusted devices that are connected to the switch.

digital certificate

A digital certificate is an electronic document that uses a digital signature to bind a public key with an identity—information such as the name of a person or an organization, address, and so forth.

Digital wireless pulse

A wireless technology for transmitting large amounts of digital data over a wide spectrum of frequency bands with very low power for a short distance. Ultra Wideband radio can carry a huge amount of data over a distance up to 230 ft at very low power (less than 0.5 mW), and has the ability to carry signals through doors and other obstacles that tend to reflect signals at more limited bandwidths and a higher power.

Disconnect-Ack

Disconnect-Ack is a NAS response packet to a Disconnect-Request, which indicates that the session was disconnected.

Disconnect-Nak

Disconnect-Nak is NAS response packet to a Disconnect-Request, which indicates that the session was not disconnected.

Disconnect-Request

Disconnect-Request is a RADIUS packet type sent to a NAS requesting that a user or session be disconnected.

distribution certificate

Distribution certificate is used for digitally signing iOS mobile apps to enable enterprise app distribution. It verifies the identity of the app publisher.

DLNA

Digital Living Network Alliance. DLNA is a set of interoperability guidelines for sharing digital media among multimedia devices.

DMO

Dynamic Multicast Optimization. DMO is a process of converting multicast streams into unicast streams over a wireless link to enhance the quality and reliability of streaming videos, while preserving the bandwidth available to non-video clients.

DN

Distinguished Name. A series of fields in a digital certificate that, taken together, constitute the unique identity of the person or device that owns the digital certificate. Common fields in a DN include country, state, locality, organization, organizational unit, and the "common name", which is the primary name used to identify the certificate.

DNS

Domain Name System. A DNS server functions as a phone book for the intranet and Internet users. It converts human-readable computer host names into IP addresses and IP addresses into host names. It stores several records for a domain name such as an address 'A' record, name server (NS), and mail exchanger (MX) records. The Address 'A' record is the most important record that is stored in a DNS server, because it provides the required IP address for a network peripheral or element.

DOCSIS

Data over Cable Service Interface Specification. A telecommunication standard for Internet access through cable modem.

DoS

Denial of Service. DoS is any type of attack where the attackers send excessive messages to flood traffic and thereby preventing the legitimate users from accessing the service.

DPD

Dead Peer Detection. A method used by the network devices to detect the availability of the peer devices.

DPI

Deep Packet Inspection. DPI is an advanced method of network packet filtering that is used for inspecting data packets exchanged between the devices and systems over a network. DPI functions at the Application layer of the Open Systems Interconnection (OSI) reference model and enables users to identify, categorize, track, reroute, or stop packets passing through a network.

DRT

Downloadable Regulatory Table. The DRT feature allows new regulatory approvals to be distributed for APs without a software upgrade or patch.

DS

Differentiated Services. The DS specification aims to provide uninterrupted quality of service by managing and controlling the network traffic, so that certain types of traffic get precedence.

DSCP

Differentiated Services Code Point. DSCP is a 6-bit packet header value used for traffic classification and priority assignment.

DSL

Digital Subscriber Line. The DSL technology allows the transmission of digital data over telephone lines. A DSL modem is a device used for connecting a computer or router to a telephone line that offers connectivity to the Internet.

DSSS

Direct-Sequence Spread Spectrum. DSSS is a modulation technique used for reducing overall signal interference. This technique multiplies the original data signal with a pseudo random noise spreading code. Spreading of this signal makes the resulting wideband channel more noisy, thereby increasing the resistance to interference. See FHSS.

DST

Daylight Saving Time. DST is also known as summer time that refers to the practice of advancing clocks, so that evenings have more daylight and mornings have less. Typically clocks are adjusted forward one hour near the start of spring and are adjusted backward in autumn.

DTE

Data Terminal Equipment. DTE refers to a device that converts user information into signals or re-converts the received signals.

DTIM

Delivery Traffic Indication Message. DTIM is a kind of traffic indication map. A DTIM interval determines when the APs must deliver broadcast and multicast frames to their associated clients in power save mode.

DTLS

Datagram Transport Layer Security. DTLS communications protocol provides communications security for datagram protocols.

dynamic authorization

Dynamic authorization refers to the ability to make changes to a visitor account's session while it is in progress. This might include disconnecting a session or updating some aspect of the authorization for the session.

dynamic NAT

Dynamic Network Address Translation. Dynamic NAT maps multiple public IP addresses and uses these addresses with an internal or private IP address. Dynamic NAT helps to secure a network by masking the internal configuration of a private network.

EAP

Extensible Authentication Protocol. An authentication protocol for wireless networks that extends the methods used by the PPP, a protocol often used when connecting a computer to the Internet. EAP can support multiple authentication mechanisms, such as token cards, smart cards, certificates, one-time passwords, and public key encryption authentication.

EAP-FAST

EAP – Flexible Authentication Secure Tunnel (tunneled).

EAP-GTC

EAP – Generic Token Card. (non-tunneled).

EAP-MD5

EAP – Method Digest 5. (non-tunneled).

EAP-MSCHAP

EAP Microsoft Challenge Handshake Authentication Protocol.

EAP-MSCHAPv2

EAP Microsoft Challenge Handshake Authentication Protocol Version 2.

EAP-PEAP

EAP–Protected EAP. A widely used protocol for securely transporting authentication data across a network (tunneled).

EAP-PWD

EAP-Password. EAP-PWD is an EAP method that uses a shared password for authentication.

EAP-TLS

EAP–Transport Layer Security. EAP-TLS is a certificate-based authentication method supporting mutual authentication, integrity-protected ciphersuite negotiation and key exchange between two endpoints. See RFC 5216.

EAP-TTLS

EAP–Tunneled Transport Layer Security. EAP-TTLS is an EAP method that encapsulates a TLS session, consisting of a handshake phase and a data phase. See RFC 5281.

EAPoL

Extensible Authentication Protocol over LAN. A network port authentication protocol used in IEEE 802.1X standards to provide a generic network sign-on to access network resources.

ECC

Elliptical Curve Cryptography or Error correcting Code memory. Elliptical Curve Cryptography is a public-key encryption technique that is based on elliptic curve theory used for creating faster, smaller, and more efficient cryptographic keys. Error Correcting Code memory is a type of computer data storage that can detect and correct the most common kinds of internal data corruption. ECC memory is used in most computers where data corruption cannot be tolerated under any circumstances, such as for scientific or financial computing.

ECDSA

Elliptic Curve Digital Signature Algorithm. ECDSA is a cryptographic algorithm that supports the use of public or private key pairs for encrypting and decrypting information.

EDCA

Enhanced Distributed Channel Access. The EDCA function in the IEEE 802.11e Quality of Service standard supports differentiated and distributed access to wireless medium based on traffic priority and Access Category types. See WMM and WME.

EIGRP

Enhanced Interior Gateway Routing Protocol. EIGRP is a routing protocol used for automating routing decisions and configuration in a network.

EIRP

Effective Isotropic Radiated Power or Equivalent Isotropic Radiated Power. EIRP refers to the output power generated when a signal is concentrated into a smaller area by the Antenna.

ESI

External Services Interface. ESI provides an open interface for integrating security solutions that solve interior network problems such as viruses, worms, spyware, and corporate compliance.

ESS

Extended Service Set. An ESS is a set of one or more interconnected BSSs that form a single sub network.

ESSID

Extended Service Set Identifier. ESSID refers to the ID used for identifying an extended service set.

Ethernet

Ethernet is a network protocol for data transmission over LAN.

EULA

End User License Agreement. EULA is a legal contract between a software application publisher or author and the users of the application.

FCC

Federal Communications Commission. FCC is a regulatory body that defines standards for the interstate and international communications by radio, television, wire, satellite, and cable.

FFT

Fast Fourier Transform. FFT is a frequency analysis mechanism that aims at faster conversion of a discrete signal in time domain into a discrete frequency domain representation. See also DFT.

FHSS

Frequency Hopping Spread Spectrum. FHSS is transmission technique that allows modulation and transmission of a data signal by rapidly switching a carrier among many frequency channels in a random but predictable sequence. See also DSSS.

FIB

Forwarding Information Base. FIB is a forwarding table that maps MAC addresses to ports. FIB is used in network bridging, routing, and similar functions to identify the appropriate interface for forwarding packets.

FIPS

Federal Information Processing Standards. FIPS refers to a set of standards that describe document processing, encryption algorithms, and other information technology standards for use within non-military government agencies, and by government contractors and vendors who work with these agencies.

firewall

Firewall is a network security system used for preventing unauthorized access to or from a private network.

FQDN

Fully Qualified Domain Name. FQDN is a complete domain name that identifies a computer or host on the Internet.

FQLN

Fully Qualified Location Name. FQLN is a device location identifier in the format: APname.Floor.Building.Campus.

frequency allocation

Use of radio frequency spectrum as regulated by governments.

FSPL

Free Space Path Loss. FSPL refers to the loss in signal strength of an electromagnetic wave that would result from a line-of-sight path through free space (usually air), with no obstacles nearby to cause reflection or diffraction.

FTP

File Transfer Protocol. A standard network protocol used for transferring files between a client and server on a computer network.

GARP

Generic Attribute Registration Protocol. GARP is a LAN protocol that allows the network nodes to register and de-register attributes, such as network addresses, with each other.

GAS

Generic Advertisement Service. GAS is a request-response protocol, which provides Layer 2 transport mechanism between a wireless client and a server in the network prior to authentication. It helps in determining a wireless network infrastructure before associating clients, and allows clients to send queries to multiple 802.11 networks in parallel.

gateway

Gateway is a network node that allows traffic to flow in and out of the network.

Gbps

Gigabits per second.

GBps

Gigabytes per second.

GET

GET refers HTTP request method or an SNMP operation method. The GET HTTP request method submits data to be processed to a specified resource. The GET SNMP operation method obtains information from the Management Information Base (MIB).

GHz

Gigahertz.

GMT

Greenwich Mean Time. GMT refers to the mean solar time at the Royal Observatory in Greenwich, London. GMT is the same as Coordinated Universal Time (UTC) standard, written as an offset of UTC +/- 00:00.

goodput

Goodput is the application level throughput that refers to the ratio of the total bytes transmitted or received in the network to the total air time required for transmitting or receiving the bytes.

GPS

Global Positioning System. A satellite-based global navigation system.

GRE

Generic Routing Encapsulation. GRE is an IP encapsulation protocol that is used to transport packets over a network.

GTC

Generic Token Card. GTC is a protocol that can be used as an alternative to MSCHAPv2 protocol. GTC allows authentication to various authentication databases even in cases where MSCHAPv2 is not supported by the database.

GVRP

GARP VLAN Registration Protocol or Generic VLAN Registration Protocol. GARP is an IEEE 802.1Q-compliant protocol that facilitates VLAN registration and controls VLANs within a larger network.

H2QP

Hotspot 2.0 Query Protocol.

hot zone

Wireless access area created by multiple hotspots that are located in close proximity to one another. Hot zones usually combine public safety APs with public hotspots.

hotspot

Hotspot refers to a WLAN node that provides Internet connection and virtual private network (VPN) access from a given location. A business traveler, for example, with a laptop equipped for Wi-Fi can look up a local hotspot, contact it, and get connected through its network to reach the Internet.

HSPA

High-Speed Packet Access.

HT

High Throughput. IEEE 802.11n is an HT WLAN standard that aims to achieve physical data rates of close to 600 Mbps on the 2.4 GHz and 5 GHz bands.

HTTP

Hypertext Transfer Protocol. The HTTP is an application protocol to transfer data over the web. The HTTP protocol defines how messages are formatted and transmitted, and the actions that the w servers and browsers should take in response to various commands.

HTTPS

Hypertext Transfer Protocol Secure. HTTPS is a variant of the HTTP that adds a layer of security on the data in transit through a secure socket layer or transport layer security protocol connection.

IAS

Internet Authentication Service. IAS is a component of Windows Server operating systems that provides centralized user authentication, authorization, and accounting.

ICMP

Internet Control Message Protocol. ICMP is an error reporting protocol. It is used by network devices such as routers, to send error messages and operational information to the source IP address when network problems prevent delivery of IP packets.

IDS

Intrusion Detection System. IDS monitors a network or systems for malicious activity or policy violations and reports its findings to the management system deployed in the network.

IEEE

Institute of Electrical and Electronics Engineers.

IGMP

Internet Group Management Protocol. Communications protocol used by hosts and adjacent routers on IP networks to establish multicast group memberships.

IGMP snooping

IGMP snooping prevents multicast flooding on Layer 2 network by treating multicast traffic as broadcast traffic. Without IGMP snooping, all streams could be flooded to all ports on that VLAN. When multicast flooding occurs, end-hosts that happen to be in the same VLAN would receive all the streams only to be discarded without snooping.

IGP

Interior Gateway Protocol. IGP is used for exchanging routing information between gateways within an autonomous system (for example, a system of corporate local area networks).

IGRP

Interior Gateway Routing Protocol. IGRP is a distance vector interior routing protocol used by routers to exchange routing data within an autonomous system.

IKE

Internet Key Exchange. IKE is a key management protocol used with IPsec protocol to establish a secure communication channel. IKE provides additional feature, flexibility, and ease of configuration for IPsec standard.

IKEv1

Internet Key Exchange version 1. IKEv1 establishes a secure authenticated communication channel by using either the pre-shared key (shared secret), digital signatures, or public key encryption. IKEv1 operates in Main and Aggressive modes. See RFC 2409.

IKEv2

Internet Key Exchange version 2. IKEv2 uses the secure channel established in Phase 1 to negotiate Security Associations on behalf of services such as IPsec. IKEv2 uses pre-shared key and Digital Signature for authentication. See RFC 4306.

IoT

Internet of Things. IoT refers to the internetworking of devices that are embedded with electronics, software, sensors, and network connectivity features allowing data exchange over the Internet.

IPM

Intelligent Power Monitoring. IPM is a feature supported on certain APs that actively measures the power utilization of an AP and dynamically adapts to the power resources.

IPS

Intrusion Prevention System. The IPS monitors a network for malicious activities such as security threats or policy violations. The main function of an IPS is to identify suspicious activity, log the information, attempt to block the activity, and report it.

IPsec

Internet Protocol security. IPsec is a protocol suite for secure IP communications that authenticates and encrypts each IP packet in a communication session.

IPSG

Internet Protocol Source Guard. IPSG restricts IP address from untrusted interface by filtering traffic based on list of addresses in the DHCP binding database or manually configured IP source bindings. It prevents IP spoofing attacks.

IrDA

An industry-sponsored organization set up in 1993 to create international standards for the hardware and software used in infrared communication links. In this special form of radio transmission, a focused ray of light in the infrared frequency spectrum, measured in terahertz (THz), or trillions of hertz (cycles per second), is modulated with information and sent from a transmitter to a receiver over a relatively short distance.

ISAKMP

Internet Security Association and Key Management Protocol. ISAKMP is used for establishing Security Associations and cryptographic keys in an Internet environment.

ISP

Internet Service Provider. An ISP is an organization that provides services for accessing and using the Internet.

JSON

JavaScript Object Notation. JSON is an open-standard, language-independent, lightweight data-interchange format used to transmit data objects consisting of attribute–value pairs. JSON uses a "self-describing" text format that is easy for humans to read and write, and that can be used as a data format by any programming language.

Kbps

Kilobits per second.

KBps

Kilobytes per second.

keepalive

Signal sent at periodic intervals from one device to another to verify that the link between the two devices is working. If no reply is received, data will be sent by a different path until the link is restored. A keepalive can also be used to indicate that the connection should be preserved so that the receiving device does not consider it timed out and drop it.

L2TP

Layer-2 Tunneling Protocol. L2TP is a networking protocol used by the ISPs to enable VPN operations.

LACP

Link Aggregation Control Protocol. LACP is used for the collective handling of multiple physical ports that can be seen as a single channel for network traffic purposes.

LAG

Link Aggregation Group . A LAG combines a number of physical ports together to make a single high-bandwidth data path. LAGs can connect two switches to provide a higher-bandwidth connection to a public network.

LAN

Local Area Network. A LAN is a network of connected devices within a distinct geographic area such as an office or a commercial establishment and share a common communications line or wireless link to a server.

LCD

Liquid Crystal Display. LCD is the technology used for displays in notebook and other smaller computers. Like LED and gas-plasma technologies, LCDs allow displays to be much thinner than the cathode ray tube technology.

LDAP

Lightweight Directory Access Protocol. LDAP is a communication protocol that provides the ability to access and maintain distributed directory information services over a network.

LDPC

Low-Density Parity-Check. LDPC is a method of transmitting a message over a noisy transmission channel using a linear error correcting code. An LDPC is constructed using a sparse bipartite graph.

LEAP

Lightweight Extensible Authentication Protocol. LEAP is a Cisco proprietary version of EAP used in wireless networks and Point-to-Point connections.

LED

Light Emitting Diode. LED is a semiconductor light source that emits light when an electric current passes through it.

LEEF

Log Event Extended Format. LEEF is a type of customizable syslog event format. An extended log file contains a sequence of lines containing ASCII characters terminated by either the sequence LF or CRLF.

LI

Lawful Interception. LI refers to the procedure of obtaining communications network data by the Law Enforcement Agencies for the purpose of analysis or evidence.

LLDP

Link Layer Discovery Protocol. LLDP is a vendor-neutral link layer protocol in the Internet Protocol suite used by network devices for advertising their identity, capabilities, and neighbors on an IEEE 802 local area network, which is principally a wired Ethernet.

LLDP-MED

LLDP-Media Endpoint Discovery. LLDP-MED facilitates information sharing between endpoints and network infrastructure devices.

LMS

Local Management Switch. In multi-controller networks, each controller acts as an LMS and terminates user traffic from the APs, processes, and forwards the traffic to the wired network.

LNS

L2TP Network Server. LNS is an equipment that connects to a carrier and handles the sessions from broadband lines. It is also used for dial-up and mobile links. LNS handles authentication and routing of the IP addresses. It also handles the negotiation of the link with the equipment and establishes a session.

LTE

Long Term Evolution. LTE is a 4G wireless communication standard that provides high-speed wireless communication for mobile phones and data terminals. See 4G.

MAB

MAC Authentication Bypass. Endpoints such as network printers, Ethernet-based sensors, cameras, and wireless phones do not support 802.1X authentication. For such endpoints, MAC Authentication Bypass mechanism is used. In this method, the MAC address of the endpoint is used to authenticate the endpoint.

MAC

Media Access Control. A MAC address is a unique identifier assigned to network interfaces for communications on a network.

MAM

Mobile Application Management. MAM refers to software and services used to secure, manage, and distribute mobile applications used in enterprise settings on mobile devices like smartphones and tablet computers. Mobile Application Management can apply to company-owned mobile devices as well as BYOD.

Mbps

Megabits per second

MBps

Megabytes per second

MCS

Modulation and Coding Scheme. MCS is used as a parameter to determine the data rate of a wireless connection for high throughput.

MD4

Message Digest 4. MD4 is an earlier version of MD5 and is an algorithm used to verify data integrity through the creation of a 128-bit message digest from data input.

MD5

Message Digest 5. The MD5 algorithm is a widely used hash function producing a 128-bit hash value from the data input.

MDAC

Microsoft Data Access Components. MDAC is a framework of interrelated Microsoft technologies that provides a standard database for Windows OS.

MDM

Mobile Device Management. MDM is an administrative software to manage, monitor, and secure mobile devices of the employees in a network.

mDNS

Multicast Domain Name System. mDNS provides the ability to perform DNS-like operations on the local link in the absence of any conventional unicast DNS server. The mDNS protocol uses IP multicast User Datagram Protocol (UDP) packets, and is implemented by the Apple Bonjour and Linux NSS-mDNS services. mDNS works in conjunction with DNS Service Discovery (DNS-SD), a companion zero-configuration technique specified. See RFC 6763.

MFA

Multi-factor Authentication. MFA lets you require multiple factors, or proofs of identity, when authenticating a user. Policy configurations define how often multi-factor authentication will be required, or conditions that will trigger it.

MHz

Megahertz

MIB

Management Information Base. A hierarchical database used by SNMP to manage the devices being monitored.

microwave

Electromagnetic energy with a frequency higher than 1 GHz, corresponding to wavelength shorter than 30 centimeters.

MIMO

Multiple Input Multiple Output. An antenna technology for wireless communications in which multiple antennas are used at both source (transmitter) and destination (receiver). The antennas at each end of the communications circuit are combined to minimize errors and optimize data speed.

MISO

Multiple Input Single Output. An antenna technology for wireless communications in which multiple antennas are used at the source (transmitter). The antennas are combined to minimize errors and optimize data speed. The destination (receiver) has only one antenna.

MLD

Multicast Listener Discovery. A component of the IPv6 suite. It is used by IPv6 routers for discovering multicast listeners on a directly attached link.

MPDU

MAC Protocol Data Unit. MPDU is a message exchanged between MAC entities in a communication system based on the layered OSI model.

MPLS

Multiprotocol Label Switching. The MPLS protocol speeds up and shapes network traffic flows.

MPPE

Microsoft Point-to-Point Encryption. A method of encrypting data transferred across PPP-based dial-up connections or PPTP-based VPN connections.

MS-CHAP

Microsoft Challenge Handshake Authentication Protocol. MS-CHAP is Password-based, challenge-response, mutual authentication protocol that uses MD4 and DES encryption.

MS-CHAPv1

Microsoft Challenge Handshake Authentication Protocol version 1. MS-CHAPv1 extends the user authentication functionality provided on Windows networks to remote workstations. MS-CHAPv1 supports only one-way authentication.

MS-CHAPv2

Microsoft Challenge Handshake Authentication Protocol version 2. MS-CHAPv2 is an enhanced version of the MS-CHAP protocol that supports mutual authentication.

MSS

Maximum Segment Size. MSS is a parameter of the options field in the TCP header that specifies the largest amount of data, specified in bytes, that a computer or communications device can receive in a single TCP segment.

MSSID

Mesh Service Set Identifier. MSSID is the SSID used by the client to access a wireless mesh network.

MSTP

Multiple Spanning Tree Protocol. MSTP configures a separate Spanning Tree for each VLAN group and blocks all but one of the possible alternate paths within each spanning tree.

MTU

Maximum Transmission Unit. MTU is the largest size packet or frame specified in octets (eight-bit bytes) that can be sent in networks such as the Internet.

MU-MIMO

Multi-User Multiple-Input Multiple-Output. MU-MIMO is a set of multiple-input and multiple-output technologies for wireless communication, in which users or wireless terminals with one or more antennas communicate with each other.

MVRP

Multiple VLAN Registration Protocol. MVRP is a Layer 2 network protocol used for automatic configuration of VLAN information on switches.

mW

milliWatts. mW is 1/1000 of a Watt. It is a linear measurement (always positive) that is generally used to represent transmission.

NAC

Network Access Control. NAC is a computer networking solution that uses a set of protocols to define and implement a policy that describes how devices can secure access to network nodes when they initially attempt to connect to a network.

NAD

Network Access Device. NAD is a device that automatically connects the user to the preferred network, for example, an AP or an Ethernet switch.

NAK

Negative Acknowledgement. NAK is a response indicating that a transmitted message was received with errors or it was corrupted, or that the receiving end is not ready to accept transmissions.

NAP

Network Access Protection. The NAP feature in the Windows Server allows network administrators to define specific levels of network access based on identity, groups, and policy compliance. The NAP Agent is a service that collects and manages health information for NAP client computers. If a client is not compliant, NAP provides a mechanism to automatically bring the client back into compliance and then dynamically increase its level of network access.

NAS

Network Access Server. NAS provides network access to users, such as a wireless AP, network switch, or dial-in terminal server.

NAT

Network Address Translation. NAT is a method of remapping one IP address space into another by modifying network address information in Internet Protocol (IP) datagram packet headers while they are in transit across a traffic routing device.

NetBIOS

Network Basic Input/Output System. A program that lets applications on different computers communicate within a LAN.

netmask

Netmask is a 32-bit mask used for segregating IP address into subnets. Netmask defines the class and range of IP addresses.

NFC

Near-Field Communication. NFC is a short-range wireless connectivity standard (ECMA-340, ISO/IEC 18092) that uses magnetic field induction to enable communication between devices when they touch or are brought closer (within a few centimeters of distance). The standard specifies a way for the devices to establish a peer-to-peer (P2P) network to exchange data.

NIC

Network Interface Card. NIC is a hardware component that allows a device to connect to the network.

Nmap

Network Mapper. Nmap is an open-source utility for network discovery and security auditing. Nmap uses IP packets to determine such things as the hosts available on a network and their services, operating systems and versions, types of packet filters/firewalls, and so on.

NMI

Non-Maskable Interrupt. NMI is a hardware interrupt that standard interrupt-masking techniques in the system cannot ignore. It typically occurs to signal attention for non-recoverable hardware errors.

NMS

Network Management System. NMS is a set of hardware and/or software tools that allow an IT professional to supervise the individual components of a network within a larger network management framework.

NOE

New Office Environment. NOE is a proprietary VoIP protocol designed by Alcatel-Lucent Enterprise.

NTP

Network Time Protocol. NTP is a protocol for synchronizing the clocks of computers over a network.

OAuth

Open Standard for Authorization. OAuth is a token-based authorization standard that allows websites or third-party applications to access user information, without exposing the user credentials.

OCSP

Online Certificate Status Protocol. OCSP is used for determining the current status of a digital certificate without requiring a CRL.

OFDM

Orthogonal Frequency Division Multiplexing. OFDM is a scheme for encoding digital data on multiple carrier frequencies.

OID

Object Identifier. An OID is an identifier used to name an object. The OIDs represent nodes or managed objects in a MIB hierarchy. The OIDs are designated by text strings and integer sequences and are formally defined as per the ASN.1 standard.

OKC

Opportunistic Key Caching. OKC is a technique available for authentication between multiple APs in a network where those APs are under common administrative control. Using OKC, a station roaming to any AP in the network will not have to complete a full authentication exchange, but will instead just perform the 4-way handshake to establish transient encryption keys.

onboarding

The process of preparing a device for use on an enterprise network, by creating the appropriate access credentials and setting up the network connection parameters.

OpenFlow

OpenFlow is an open communications interface between control plane and the forwarding layers of a network.

OpenFlow agent

OpenFlow agent. OpenFlow is a software module in Software-Defined Networking (SDN) that allows the abstraction of any legacy network element, so that it can be integrated and managed by the SDN controller. OpenFlow runs on network devices such as switches, routers, wireless controllers, and APs.

Optical wireless

Optical wireless is combined use of conventional radio frequency wireless and optical fiber for telecommunication. Long-range links are provided by using optical fibers; the links from the long-range endpoints to end users are accomplished by RF wireless or laser systems. RF wireless at Ultra High Frequencies and microwave frequencies can carry broadband signals to individual computers at substantial data speeds.

OSI

Open Systems Interconnection. OSI is a reference model that defines a framework for communication between the applications in a network.

OSPF

Open Shortest Path First. OSPF is a link-state routing protocol for IP networks. It uses a link-state routing algorithm and falls into the group of interior routing protocols that operates within a single Autonomous System (AS).

OSPFv2

Open Shortest Path First version 2. OSPFv2 is the version 2 of the link-state routing protocol, OSPF. See RFC 2328.

OUI

Organizationally Unique Identifier. Synonymous with company ID or vendor ID, an OUI is a 24-bit, globally unique assigned number, referenced by various standards. The first half of a MAC address is OUI.

OVA

Open Virtualization Archive. OVA contains a compressed installable version of a virtual machine.

OVF

Open Virtualization Format. OVF is a specification that describes an open-standard, secure, efficient, portable and extensible format for packaging and distributing software for virtual machines.

PAC

Protected Access Credential. PAC is distributed to clients for optimized network authentication. These credentials are used for establishing an authentication tunnel between the client and the authentication server.

PAP

Password Authentication Protocol. PAP validates users by password. PAP does not encrypt passwords for transmission and is thus considered insecure.

PAPI

Process Application Programming Interface. PAPI controls channels for ARM and Wireless Intrusion Detection System (WIDS) communication to the master controller. A separate PAPI control channel connects to the local controller where the SSID tunnels terminate.

PBR

Policy-based Routing. PBR provides a flexible mechanism for forwarding data packets based on polices configured by a network administrator.

PDU

Power Distribution Unit or Protocol Data Unit. Power Distribution Unit is a device that distributes electric power to the networking equipment located within a data center. Protocol Data Unit contains protocol control Information that is delivered as a unit among peer entities of a network.

PEAP

Protected Extensible Authentication Protocol. PEAP is a type of EAP communication that addresses security issues associated with clear text EAP transmissions by creating a secure channel encrypted and protected by TLS.

PEF

Policy Enforcement Firewall. PEF also known as PEFNG provides context-based controls to enforce application-layer security and prioritization. The customers using Aruba mobility controllers can avail PEF features and services by obtaining a PEF license. PEF for VPN users—Customers with PEF for VPN license can apply firewall policies to the user traffic routed to a controller through a VPN tunnel.

PEFNG

Policy Enforcement Firewall. PEF also known as PEFNG provides context-based controls to enforce application-layer security and prioritization. The customers using Aruba mobility controllers can avail PEF features and services by obtaining a PEF license. PEF for VPN users—Customers with PEF for VPN license can apply firewall policies to the user traffic routed to a controller through a VPN tunnel.

PEFV

Policy Enforcement Firewall. PEF also known as PEFNG provides context-based controls to enforce application-layer security and prioritization. The customers using Aruba mobility controllers can avail PEF features and services by obtaining a PEF license. PEF for VPN users—Customers with PEF for VPN license can apply firewall policies to the user traffic routed to a controller through a VPN tunnel.

PFS

Perfect Forward Secrecy. PFS refers to the condition in which a current session key or long-term private key does not compromise the past or subsequent keys.

PHB

Per-hop behavior. PHB is a term used in DS or MPLS. It defines the policy and priority applied to a packet when traversing a hop (such as a router) in a DiffServ network.

PIM

Protocol-Independent Multicast. PIM refers to a family of multicast routing protocols for IP networks that provide one-to-many and many-to-many distribution of data over a LAN, WAN, or the Internet.

PIN

Personal Identification Number. PIN is a numeric password used to authenticate a user to a system.

PKCS#n

Public-key cryptography standard n. PKCS#n refers to a numbered standard related to topics in cryptography, including private keys (PKCS#1), digital certificates (PKCS#7), certificate signing requests (PKCS#10), and secure storage of keys and certificates (PKCS#12).

PKI

Public Key Infrastructure. PKI is a security technology based on digital certificates and the assurances provided by strong cryptography. See also certificate authority, digital certificate, public key, private key.

PLMN

Public Land Mobile Network. PLMS is a network established and operated by an administration or by a Recognized Operating Agency for the specific purpose of providing land mobile telecommunications services to the public.

PMK

Pairwise Master Key. PMK is a shared secret key that is generated after PSK or 802.1X authentication.

PoE

Power over Ethernet. PoE is a technology for wired Ethernet LANs to carry electric power required for the device in the data cables. The IEEE 802.3af PoE standard provides up to 15.4 W of power on each port.

PoE+

Power over Ethernet+. PoE+ is an IEEE 802.3at standard that provides 25.5W power on each port.

POST

Power On Self Test. An HTTP request method that requests data from a specified resource.

PPP

Point-to-Point Protocol. PPP is a data link (layer 2) protocol used to establish a direct connection between two nodes. It can provide connection authentication, transmission encryption, and compression.

PPPoE

Point-to-Point Protocol over Ethernet. PPPoE is a method of connecting to the Internet, typically used with DSL services, where the client connects to the DSL modem.

PPTP

Point-to-Point Tunneling Protocol. PPTP is a method for implementing virtual private networks. It uses a control channel over TCP and a GRE tunnel operating to encapsulate PPP packets.

private key

The part of a public-private key pair that is always kept private. The private key encrypts the signature of a message to authenticate the sender. The private key also decrypts a message that was encrypted with the public key of the sender.

PRNG

Pseudo-Random Number Generator. PRNG is an algorithm for generating a sequence of numbers whose properties approximate the properties of sequences of random numbers.

PSK

Pre-shared key. A unique shared secret that was previously shared between two parties by using a secure channel. This is used with WPA security, which requires the owner of a network to provide a passphrase to users for network access.

PSU

Power Supply Unit. PSU is a unit that supplies power to an equipment by converting mains AC to low-voltage regulated DC power.

public key

The part of a public-private key pair that is made public. The public key encrypts a message and the message is decrypted with the private key of the recipient.

PVST

Per-VLAN Spanning Tree. PVST provides load balancing of VLANs across multiple ports resulting in optimal usage of network resources.

PVST+

Per-VLAN Spanning Tree+. PVST+ is an extension of the PVST standard that uses the 802.1Q trunking technology.

QoS

Quality of Service. It refers to the capability of a network to provide better service and performance to a specific network traffic over various technologies.

RA

Router Advertisement. The RA messages are sent by the routers in the network when the hosts send multicast router solicitation to the multicast address of all routers.

Radar

Radio Detection and Ranging. Radar is an object-detection system that uses radio waves to determine the range, angle, or velocity of objects.

RADIUS

Remote Authentication Dial-In User Service. An Industry-standard network access protocol for remote authentication. It allows authentication, authorization, and accounting of remote users who want to access network resources.

RAM

Random Access Memory.

RAPIDS

Rogue Access Point identification and Detection System. An AMP module that is designed to identify and locate wireless threats by making use of all of the information available from your existing infrastructure.

RARP

Reverse Address Resolution Protocol. RARP is a protocol used by a physical machine in a local area network for determining the IP address from the ARP table or cache of the gateway server.

Regex

Regular Expression. Regex refers to a sequence of symbols and characters defining a search pattern.

Registration Authority

Type of Certificate Authority that processes certificate requests. The Registration Authority verifies that requests are valid and comply with certificate policy, and authenticates the user's identity. The Registration Authority then forwards the request to the Certificate Authority to sign and issue the certificate.

Remote AP

Remote APs extend corporate network to the users working from home or at temporary work sites. Remote APs are deployed at branch office sites and are connected to the central network on a WAN

link.

REST

Representational State Transfer. REST is a simple and stateless architecture that the web services use for providing interoperability between computer systems on the Internet. In a RESTful web service, requests made to the URI of a resource will elicit a response that may be in XML, HTML, JSON or some other defined format.

RF

Radio Frequency. RF refers to the electromagnetic wave frequencies within a range of 3 kHz to 300 GHz, including the frequencies used for communications or Radar signals.

RFC

Request For Comments. RFC is a commonly used format for the Internet standards documents.

RFID

Radio Frequency Identification. RFID uses radio waves to automatically identify and track the information stored on a tag attached to an object.

RIP

Routing Information Protocol. RIP prevents the routing loops by limiting the number of hops allowed in a path from source to destination.

RJ45

Registered Jack 45. RJ45 is a physical connector for network cables.

RMA

Return Merchandise Authorization. RMA is a part of the product returning process that authorizes users to return a product to the manufacturer or distributor for a refund, replacement, or repair. The customers who want to return a product within its Warranty period contact the manufacturer to initiate the product returning process. The manufacturer or the seller generates an authorization number for the RMA, which is used by the customers, when returning a product to the warehouse.

RMON

Remote Monitoring. RMON provides standard information that a network administrator can use to monitor, analyze, and troubleshoot a group of distributed LANs.

RoW

Rest of World. RoW or RW is an operating country code of a device.

RSA

Rivest, Shamir, Adleman. RSA is a cryptosystem for public-key encryption, and is widely used for securing sensitive data, particularly when being sent over an insecure network such as the Internet.

RSSI

Received Signal Strength Indicator. RSSI is a mechanism by which RF energy is measured by the circuitry on a wireless NIC (0-255). The RSSI is not standard across vendors. Each vendor determines its own RSSI scale/values.

RSTP

Rapid Spanning Tree Protocol. RSTP provides significantly faster spanning tree convergence after a topology change, introducing new convergence behaviors and bridge port roles to do this.

RTCP

RTP Control Protocol. RTCP provides out-of-band statistics and control information for an Real-Time Transport Protocol session.

RTLS

Real-Time Location Systems. RTLS automatically identifies and tracks the location of objects or people in real time, usually within a building or other contained area.

RTP

Real-Time Transport Protocol. RTP is a network protocol used for delivering audio and video over IP networks.

RTS

Request to Send. RTS refers to the data transmission and protection mechanism used by the 802.11 wireless networking protocol to prevent frame collision occurrences. See CTS.

RTSP

Real Time Streaming Protocol. RTSP is a network control protocol designed for use in entertainment and communications systems to control streaming media servers.

RVI

Routed VLAN Interface. RVI is a switch interface that forwards packets between VLANs.

RW

Rest of World. RoW or RW is an operating country code of a device.

SA

Security Association. SA is the establishment of shared security attributes between two network entities to support secure communication.

SAML

Security Assertion Markup Language. SAML is an XML-based framework for communicating user authentication, entitlement, and attribute information. SAML enables single sign-on by allowing users to authenticate at an identity provider and then access service providers without additional authentication.

SCEP

Simple Certificate Enrollment Protocol. SCEP is a protocol for requesting and managing digital certificates.

SCP

Secure Copy Protocol. SCP is a network protocol that supports file transfers between hosts on a network.

SCSI

Small Computer System Interface. SCSI refers to a set of interface standards for physical connection and data transfer between a computer and the peripheral devices such as printers, disk drives, CD-ROM, and so on.

SD-WAN

Software-Defined Wide Area Network. SD-WAN is an application for applying SDN technology to WAN connections that connect enterprise networks across disparate geographical locations.

SDN

Software-Defined Networking. SDN is an umbrella term encompassing several kinds of network technology aimed at making the network as agile and flexible as the virtualized server and storage infrastructure of the modern data center.

SDR

Server Derivation Rule. An SDR refers to a role assignment model used by the controllers running ArubaOS to assign roles and VLANs to the WLAN users based on the rules defined under a server group. The SDRs override the default authentication roles and VLANs defined in the AAA and Virtual AP profiles.

SDU

Service Data Unit. SDU is a unit of data that has been passed down from an OSI layer to a lower layer and that has not yet been encapsulated into a PDU by the lower layer.

SFP

The Small Form-factor Pluggable. SFP is a compact, hot-pluggable transceiver that is used for both telecommunication and data communications applications.

SFP+

Small Form-factor Pluggable+. SFP+ supports up to data rates up to 16 Gbps.

SFTP

Secure File Transfer Protocol. SFTP is a network protocol that allows file access, file transfer, and file management functions over a secure connection.

SHA

Secure Hash Algorithm. SHA is a family of cryptographic hash functions. The SHA algorithm includes the SHA, SHA-1, SHA-2 and SHA-3 variants.

SIM

Subscriber Identity Module. SIM is an integrated circuit that is intended to securely store the International Mobile Subscriber Identity (IMSI) number and its related key, which are used for identifying and authenticating subscribers on mobile telephony devices.

SIP

Session Initiation Protocol. SIP is used for signaling and controlling multimedia communication session such as voice and video calls.

SIRT

Security Incident Response Team. SIRT is responsible for reviewing as well as responding to computer security incident reports and activity.

SKU

Stock Keeping Unit. SKU refers to the product and service identification code for the products in the inventory.

SLAAC

Stateless Address Autoconfiguration. SLAAC provides the ability to address a host based on a network prefix that is advertised from a local network router through router advertisements.

SMB

Server Message Block or Small and Medium Business. Server Message Block operates as an application-layer network protocol mainly used for providing shared access to files, printers, serial ports, and for miscellaneous communications between the nodes on a network.

SMS

Short Message Service. SMS refers to short text messages (up to 140 characters) sent and received through mobile phones.

SMTP

Simple Mail Transfer Protocol. SMTP is an Internet standard protocol for electronic mail transmission.

SNIR

Signal-to-Noise-Plus-Interference Ratio. SNIR refers to the power of a central signal of interest divided by the sum of the interference power and the power of the background noise. SINR is defined as the power of a certain signal of interest divided by the sum of the interference power (from all the other interfering signals) and the power of some background noise.

SNMP

Simple Network Management Protocol. SNMP is a TCP/IP standard protocol for managing devices on IP networks. Devices that typically support SNMP include routers, switches, servers, workstations, printers, modem racks, and more. It is used mostly in network management systems to monitor network-attached devices for conditions that warrant administrative attention.

SNMPv1

Simple Network Management Protocol version 1. SNMPv1 is a widely used network management protocol.

SNMPv2

Simple Network Management Protocol version 2. SNMPv2 is an enhanced version of SNMPv1, which includes improvements in the areas of performance, security, confidentiality, and manager-to-manager communications.

SNMPv2c

Community-Based Simple Network Management Protocol version 2. SNMPv2C uses the community-based security scheme of SNMPv1 and does not include the SNMPv2 security model.

SNMPv3

Simple Network Management Protocol version 3. SNMPv3 is an enhanced version of SNMP that includes security and remote configuration features.

SNR

Signal-to-Noise Ratio. SNR is used for comparing the level of a desired signal with the level of background noise.

SNTP

Simple Network Time Protocol. SNTP is a less complex implementation of NTP. It uses the same , but does not require the storage of state over extended periods of time.

SOAP

Simple Object Access Protocol. SOAP enables communication between the applications running on different operating systems, with different technologies and programming languages. SOAP is an XML-based messaging protocol for exchanging structured information between the systems that support web services.

SoC

System on a Chip. SoC is an Integrated Circuit that integrates all components of a computer or other electronic system into a single chip.

source NAT

Source NAT changes the source address of the packets passing through the router. Source NAT is typically used when an internal (private) host initiates a session to an external (public) host.

SSH

Secure Shell. SSH is a network protocol that provides secure access to a remote device.

SSID

Service Set Identifier. SSID is a name given to a WLAN and is used by the client to access a WLAN network.

SSL

Secure Sockets Layer. SSL is a computer networking protocol for securing connections between network application clients and servers over the Internet.

SSO

Single Sign-On. SSO is an access-control property that allows the users to log in once to access multiple related, but independent applications or systems to which they have privileges. The process authenticates the user across all allowed resources during their session, eliminating additional login prompts.

STBC

Space-Time Block Coding. STBC is a technique used in wireless communications to transmit multiple copies of a data stream across a number of antennas and to exploit the various received versions of the data to improve the reliability of data transfer.

STM

Station Management. STM is a process that handles AP management and user association.

STP

Spanning Tree Protocol. STP is a network protocol that builds a logical loop-free topology for Ethernet networks.

SU-MIMO

Single-User Multiple-Input Multiple-Output. SU-MIMO allocates the full bandwidth of the AP to a single high-speed device during the allotted time slice.

subnet

Subnet is the logical division of an IP network.

subscription

A business model where a customer pays a certain amount as subscription price to obtain access to a product or service.

SVP

SpectraLink Voice Priority. SVP is an open, straightforward QoS approach that has been adopted by most leading vendors of WLAN APs. SVP favors isochronous voice packets over asynchronous data packets when contending for the wireless medium and when transmitting packets onto the wired LAN.

SWAN

Structured Wireless-Aware Network. A technology that incorporates a Wireless Local Area Network (WLAN) into a wired Wide Area Network (WAN). SWAN technology can enable an existing wired network to serve hundreds of users, organizations, corporations, or agencies over a large geographic area. SWAN is said to be scalable, secure, and reliable.

TAC

Technical Assistance Center.

TACACS

Terminal Access Controller Access Control System. TACACS is a family of protocols that handles remote authentication and related services for network access control through a centralized server.

TACACS+

Terminal Access Controller Access Control System+. TACACS+ provides separate authentication, authorization, and accounting services. It is derived from, but not backward compatible with, TACACS.

TCP

Transmission Control Protocol. TCP is a communication protocol that defines the standards for establishing and maintaining network connection for applications to exchange data.

TCP/IP

Transmission Control Protocol/ Internet Protocol. TCP/IP is the basic communication language or protocol of the Internet.

TFTP

Trivial File Transfer Protocol. The TFTP is a software utility for transferring files from or to a remote host.

TIM

Traffic Indication Map. TIM is an information element that advertises if any associated stations have buffered unicast frames. APs periodically send the TIM within a beacon to identify the stations that are using power saving mode and the stations that have undelivered data buffered on the AP.

TKIP

Temporal Key Integrity Protocol. A part of the WPA encryption standard for wireless networks. TKIP is the next-generation Wired Equivalent Privacy (WEP) that provides per-packet key mixing to address the flaws encountered in the WEP standard.

TLS

Transport Layer Security. TLS is a cryptographic protocol that provides communication security over the Internet. TLS encrypts the segments of network connections above the Transport Layer by using asymmetric cryptography for key exchange, symmetric encryption for privacy, and message authentication codes for message integrity.

TLV

Type-length-value or Tag-Length-Value. TLV is an encoding format. It refers to the type of data being processed, the length of the value, and the value for the type of data being processed.

ToS

Type of Service. The ToS field is part of the IPv4 header, which specifies datagrams priority and requests a route for low-delay, high-throughput, or a highly reliable service.

TPC

Transmit Power Control. TPC is a part of the 802.11h amendment. It is used to regulate the power levels used by 802.11a radio cards.

TPM

Trusted Platform Module. TPM is an international standard for a secure cryptoprocessor, which is a dedicated microcontroller designed to secure hardware by integrating cryptographic keys into devices.

TSF

Timing Synchronization Function. TSF is a WLAN function that is used for synchronizing the timers for all the stations in a BSS.

TSPEC

Traffic Specification. TSPEC allows an 802.11e client or a QoS-capable wireless client to signal its traffic requirements to the AP.

TSV

Tab-Separated Values. TSV is a file format that allows the exchange of tabular data between applications that use different internal data formats.

TTL

Time to Live. TTL or hop limit is a mechanism that sets limits for data expiry in a computer or network.

TTY

TeleTypeWriter. TTY-enabled devices allow telephones to transmit text communications for people who are deaf or hard of hearing as well as transmit voice communication.

TXOP

Transmission Opportunity. TXOP is used in wireless networks supporting the IEEE 802.11e Quality of Service (QoS) standard. Used in both EDCA and HCF Controlled Channel Access modes of operation, TXOP is a bounded time interval in which stations supporting QoS are permitted to transfer a series of frames. TXOP is defined by a start time and a maximum duration.

U-APSD

Unscheduled Automatic Power Save Delivery. U-APSD is a part of 802.11e and helps considerably in increasing the battery life of VoWLAN terminals.

UAM

Universal Access Method. UAM allows subscribers to access a wireless network after they successfully log in from a web browser.

UCC

Unified Communications and Collaboration. UCC is a term used to describe the integration of various communications methods with collaboration tools such as virtual whiteboards, real-time audio and video conferencing, and enhanced call control capabilities.

UDID

Unique Device Identifier. UDID is used to identify an iOS device.

UDP

User Datagram Protocol. UDP is a part of the TCP/IP family of protocols used for data transfer. UDP is typically used for streaming media. UDP is a stateless protocol, which means it does not acknowledge that the packets being sent have been received.

UDR

User Derivation Rule. UDR is a role assignment model used by the controllers running ArubaOS to assign roles and VLANs to the WLAN users based on MAC address, BSSID, DHCP-Option, encryption type, SSID, and the location of a user. For example, for an SSID with captive portal in the initial role, a UDR can be configured for scanners to provide a role based on their MAC OUI.

UHF

Ultra high frequency. UHF refers to radio frequencies between the range of 300 MHz and 3 GHz. UHF is also known as the decimeter band as the wavelengths range from one meter to one decimeter.

UI

User Interface.

UMTS

Universal Mobile Telecommunication System. UMTS is a third generation mobile cellular system for networks. See 3G.

UPnP

Universal Plug and Play. UPnP is a set of networking protocols that permits networked devices, such as personal computers, printers, Internet gateways, Wi-Fi APs, and mobile devices to seamlessly discover each other's presence on the network and establish functional network services for data sharing, communications, and entertainment.

URI

Uniform Resource Identifier. URI identifies the name and the location of a resource in a uniform format.

URL

Uniform Resource Locator. URL is a global address used for locating web resources on the Internet.

USB

Universal Serial Bus. USB is a connection standard that offers a common interface for communication between the external devices and a computer. USB is the most common port used in the client devices.

UTC

Coordinated Universal Time. UTC is the primary time standard by which the world regulates clocks and time.

UWB

Ultra-Wideband. UWB is a wireless technology for transmitting large amounts of digital data over a wide spectrum of frequency bands with very low power for a short distance.

VA

Virtual Appliance. VA is a pre-configured virtual machine image, ready to run on a hypervisor.

VBR

Virtual Beacon Report. VBR displays a report with the MAC address details and RSSI information of an AP.

VHT

Very High Throughput. IEEE 802.11ac is an emerging VHT WLAN standard that could achieve physical data rates of close to 7 Gbps for the 5 GHz band.

VIA

Virtual Intranet Access. VIA provides secure remote network connectivity for Android, Apple iOS, Mac OS X, and Windows mobile devices and laptops. It automatically scans and selects the best secure connection to the corporate network.

VLAN

Virtual Local Area Network. In computer networking, a single Layer 2 network may be partitioned to create multiple distinct broadcast domains, which are mutually isolated so that packets can only

pass between them through one or more routers; such a domain is referred to as a Virtual Local Area Network, Virtual LAN, or VLAN.

VM

Virtual Machine. A VM is an emulation of a computer system. VMs are based on computer architectures and provide functionality of a physical computer.

VoIP

Voice over IP. VoIP allows transmission of voice and multimedia content over an IP network.

VoWLAN

Voice over WLAN. VoWLAN is a method of routing telephone calls for mobile users over the Internet using the technology specified in IEEE 802.11b. Routing mobile calls over the Internet makes them free, or at least much less expensive than they would be otherwise.

VPN

Virtual Private Network. VPN enables secure access to a corporate network when located remotely. It enables a computer to send and receive data across shared or public networks as if it were directly connected to the private network, while benefiting from the functionality, security, and management policies of the private network. This is done by establishing a virtual point-to-point connection through the use of dedicated connections, encryption, or a combination of the two.

VRD

Validated Reference Design. VRDs are guides that capture the best practices for a particular technology in field.

VRF

VisualRF. VRF is an AirWave Management Platform (AMP) module that provides a real-time, network-wide views of your entire Radio Frequency environment along with floor plan editing capabilities. VRF also includes overlays on client health to help diagnose issues related to clients, floor plan, or a specific location.

VRF Plan

VisualRF Plan. A stand-alone Windows client used for basic planning procedures such as adding a floor plan, provisioning APs, and generating a Bill of Materials report.

VRRP

Virtual Router Redundancy Protocol. VRRP is an election protocol that dynamically assigns responsibility for a virtual router to one of the VRRP routers on a LAN.

VSA

Vendor-Specific Attribute. VSA is a method for communicating vendor-specific information between NASs and RADIUS servers.

VTP

VLAN Trunking Protocol. VTP is a Cisco proprietary protocol for propagating VLANs on a LAN.

W-CDMA

Wideband Code-Division Multiple Access. W-CDMA is a third-generation (3G) mobile wireless technology that promises much higher data speeds to mobile and portable wireless devices.

walled garden

Walled garden is a feature that allows blocking of unauthorized users from accessing network resources.

WAN

Wide Area Network. WAN is a telecommunications network or computer network that extends over a large geographical distance.

WASP

Wireless Application Service Provider. WASP provides a web-based access to applications and services that would otherwise have to be stored locally and makes it possible for customers to access the service from a variety of wireless devices, such as a smartphone or Personal Digital Assistant (PDA).

WAX

Wireless abstract XML. WAX is an abstract markup language and a set of tools that is designed to help wireless application development as well as portability. Its tags perform at a higher level of abstraction than that of other wireless markup languages such as HTML, HDML, WML, XSL, and more.

web service

Web services allow businesses to share and process data programmatically. Developers who want to provide integrated applications can use the API to programmatically perform actions that would otherwise require manual operation of the user interface.

WEP

Wired Equivalent Privacy. WEP is a security protocol that is specified in 802.11b and is designed to provide a WLAN with a level of security and privacy comparable to what is usually expected of a wired LAN.

WFA

Wi-Fi Alliance. WFA is a non-profit organization that promotes Wi-Fi technology and certifies Wi-Fi products if they conform to certain standards of interoperability.

Wi-Fi

Wi-Fi is a technology that allows electronic devices to connect to a WLAN network, mainly using the 2.4 GHz and 5 GHz radio bands. Wi-Fi can apply to products that use any 802.11 standard.

WIDS

Wireless Intrusion Detection System. WIDS is an application that detects the attacks on a wireless network or wireless system.

WiMAX

Worldwide Interoperability for Microwave Access. WiMAX refers to the implementation of IEEE 802.16 family of wireless networks standards set by the WiMAX forum.

WIP

Wireless Intrusion Protection. The WIP module provides wired and wireless AP detection, classification, and containment. It detects Denial of Service (DoS) and impersonation attacks, and prevents client and network intrusions.

WIPS

Wireless Intrusion Prevention System. WIPS is a dedicated security device or integrated software application that monitors the radio spectrum of WLAN network for rogue APs and other wireless threats.

WISP

Wireless Internet Service Provider. WISP allows subscribers to connect to a server at designated hotspots using a wireless connection such as Wi-Fi. This type of ISP offers broadband service and allows subscriber computers called stations, to access the Internet and the web from anywhere within the zone of coverage provided by the server antenna, usually a region with a radius of several kilometers.

WISPr

Wireless Internet Service Provider Roaming. The WISPr framework enables the client devices to roam between the wireless hotspots using different ISPs.

WLAN

Wireless Local Area Network. WLAN is a 802.11 standards-based LAN that the users access through a wireless connection.

WME

Wireless Multimedia Extension. WME is a Wi-Fi Alliance interoperability certification, based on the IEEE 802.11e standard. It provides basic QoS features to IEEE 802.11 networks. WMM prioritizes traffic according to four ACs: voice (AC_VO), video (AC_VI), best effort (AC_BE) and background (AC_BK). See WMM.

WMI

Windows Management Instrumentation. WMI consists of a set of extensions to the Windows Driver Model that provides an operating system interface through which instrumented components provide information and notification.

WMM

Wi-Fi Multimedia. WMM is also known as WME. It refers to a Wi-Fi Alliance interoperability certification, based on the IEEE 802.11e standard. It provides basic QoS features to IEEE 802.11 networks. WMM prioritizes traffic according to four ACs: voice (AC_VO), video (AC_VI), best effort (AC_BE), and background (AC_BK).

WPA

Wi-Fi Protected Access. WPA is an interoperable wireless security specification subset of the IEEE 802.11 standard. This standard provides authentication capabilities and uses TKIP for data encryption.

WPA2

Wi-Fi Protected Access 2. WPA2 is a certification program maintained by IEEE that oversees standards for security over wireless networks. WPA2 supports IEEE 802.1X/EAP authentication or PSK technology, but includes advanced encryption mechanism using CCMP that is referred to as AES.

WSDL

Web Service Description Language. WSDL is an XML-based interface definition language used to describe the functionality provided by a web service.

WSP

Wireless Service Provider. The service provider company that offers transmission services to users of wireless devices through Radio Frequency (RF) signals rather than through end-to-end wire communication.

WWW

World Wide Web.

X.509

X.509 is a standard for a public key infrastructure for managing digital certificates and public-key encryption. It is an essential part of the Transport Layer Security protocol used to secure web and email communication.

XAuth

Extended Authentication. XAuth provides a mechanism for requesting individual authentication information from the user, and a local user database or an external authentication server. It provides a method for storing the authentication information centrally in the local network.

XML

Extensible Markup Language. XML is a markup language that defines a set of rules for encoding documents in a format that is both human-readable and machine-readable.

XML-RPC

XML Remote Procedure Call. XML-RPC is a protocol that uses XML to encode its calls and HTTP as a transport mechanism. Developers who want to provide integrated applications can use the API to programmatically perform actions that would otherwise require manual operation of the user interface.

ZTP

Zero Touch Provisioning. ZTP is a device provisioning mechanism that allows automatic and quick provisioning of devices with a minimal or at times no manual intervention.
