Following lists the updates to the ArubaOS CLI:

- [ArubaOS 8.11.1.0](#)
- [ArubaOS 8.11.0.0](#)
- [ArubaOS 8.10.0.0](#)
- [ArubaOS 8.9.0.0](#)
- [ArubaOS 8.8.0.0](#)
- [ArubaOS 8.7.0.0](#)
- [ArubaOS 8.6.0.0](#)
- [ArubaOS 8.5.0.0](#)
- [ArubaOS 8.4.0.0](#)
- [ArubaOS 8.3.0.0](#)
- [ArubaOS 8.2.2.0](#)
- [ArubaOS 8.2.1.0](#)
- [ArubaOS 8.2.0.0](#)
- [ArubaOS 8.1.0.0](#)
- [ArubaOS 8.0.1.0](#)

This guide describes the ArubaOS 8.x commands. The commands in this guide are listed alphabetically. The following information is provided for each command:

- **Command Syntax**—The complete syntax of the command.
- **Description**—A brief description of the command, including usage guidelines, prerequisites, prohibitions, and related commands.
- **Example**—An example of how to execute the command.
- **Command History**—The version of ArubaOS 8.x in which the command was first introduced, including the modification history.
- **Command Information**—This table describes any licensing requirements, command modes and platforms for which this command is applicable. For more information about available licenses, refer to the *Aruba Mobility Conductor Licensing Guide*.

Connecting to the Mobility Conductor or Managed Device

This section describes how to connect to the Mobility Conductor or Managed Device to use the CLI.

Serial Port Connection

The serial port is located on the front panel of the managed device. Connect a terminal or PC or workstation running a terminal emulation program to the serial port on the managed device to use the CLI. Configure your terminal or terminal emulation program to use the following communication settings.

Baud Rate	Data Bits	Parity	Stop Bits	Flow Control
9600	8	None	1	None

The Aruba 7200 Series controller supports baud rates between 9600 and 115200.

Telnet or SSH Connection

Telnet or SSH access requires that you configure an IP address and a default gateway on Mobility Conductor/Managed Device and connect the Mobility Conductor/Managed Device to your network. This is typically performed when you run the initial setup on the Mobility Conductor/Managed Device, as described in the *ArubaOS 8.x Quick Start Guide*. In certain deployments, you can also configure a loopback address for the Mobility Conductor/Managed Device; see [interface loopback on page 749](#) for more information.

Configuration changes on Mobility Conductor

Some commands can only be issued when connected to Mobility Conductor. If you make a configuration change on Mobility Conductor, all connected managed devices using that configuration will subsequently update their settings as well.

CLI Access

When you connect to the Mobility Conductor using the CLI, the system displays the login prompt. Log in using the admin user account and the password you entered during the initial setup on the Mobility Conductor . For example:

```
login as: admin
admin@192.0.2.1's password:
Last login: Sat Jun 25 01:17:11 2016 from 192.0.2.77
```

When you are logged in, the *enable* mode CLI prompt displays. For example:

```
(host) [mynode] #
```

All **show** commands and certain management functions are available in the enable (also called “privileged”) mode.

Configuration commands are available in *config* mode. Move from enable mode to config mode by entering **configure terminal** at the # prompt:

```
(host) [mynode]# configure terminal
Enter Configuration commands, one per line. End with CNTL/Z
```

When you are in basic config mode, (config) appears before the # prompt:

```
(host) [mynode] (config) #
```

There are several other sub-command modes that allow users to configure individual interfaces, sub-interfaces, loopback addresses, GRE tunnels and cellular profiles. For details on the prompts and the available commands for each of these modes, see [Command Modes on page 7](#).

Command Help

You can use the question mark (?) to view various types of command help.

When typed at the beginning of a line, the question mark lists all the commands available in your current mode or sub-mode. A brief explanation follows each command. For example:

```
(host) [mynode] #aaa ?
authentication      Authentication
inservice           Bring authentication server into service
ipv6                Internet Protocol Version 6
query-user          Query User
test-server         Test authentication server
user                User commands
```

When typed at the end of a possible command or abbreviation, the question mark lists the commands that match (if any). For example:

```
(host) [mynode] #c?  
ccm-debug          Centralized Configuration Module debug information  
cd                 Change current config node  
change-config-node Change current config node  
clear              Clear configuration  
clock              Append clock to cli output  
cluster-debug      Cluster Debug  
configure          Configuration Commands  
copy               Copy Files  
copy-provisioning-par.. Copy a provisioning-ap-list entry to provisioning-params  
crypto             Configure IPsec, IKE, and CA
```

If more than one item is shown, type more of the keyword characters to distinguish your choice. However, if only one item is listed, the keyword or abbreviation is valid and you can press tab or the spacebar to advance to the next keyword.

When typed in place of a parameter, the question mark lists the available options. For example:

```
(host) [mynode] #write ?  
erase              Erase and start from scratch  
memory             Write to memory  
terminal           Write to terminal  
<cr>
```

The <cr> indicates that the command can be entered without additional parameters. Any other parameters are optional.

Command Completion

To make command input easier, you can usually abbreviate each key word in the command. You need type only enough of each keyword to distinguish it from similar commands. For example:

```
(host) [mynode] #configure terminal
```

could also be entered as:

```
(host) [mynode] #con t
```

Three characters (**con**) represent the shortest abbreviation allowed for **configure**. Typing only **c** or **co** would not work because there are other commands (like **copy**) which also begin with those letters. The configure command is the only one that begins with **con**.

As you type, you can press the spacebar or tab to move to the next keyword. The system then attempts to expand the abbreviation for you. If there is only one command keyword that matches the abbreviation, it is filled in for you automatically. If the abbreviation is too vague (too few characters), the cursor does not advance and you must type more characters or use the help feature to list the matching commands.

Deleting Configuration Settings

Use the **no** command to delete or negate previously-entered configurations or parameters.

- To view a list of no commands, type **no** at the enable or config prompt followed by the question mark. For example:

```
(host) [mynode] (config) # no?
```

- To delete a configuration, use the **no** form of a configuration command. For example, the following command removes a configured user role:

```
(host) [mynode] (config) # no user-role <name>
```

- To negate a specific configured parameter, use the **no** parameter within the command. For example, the following commands delete the DSCP priority map for a priority map configuration:

```
(host) [mynode] (config) # priority-map <name>
(host) [mynode] (config-priority-map) # no dscp priority high
```

Command Modes

The ArubaOS CLI offers different levels of user access by differentiating between different command modes.

When you first log in to the CLI, you start your session in *User* mode, which provides only limited access for basic operational testing. You must enter an additional password to access *Enable* mode, which allows you to issue show commands run certain management functions. Configuration commands can only be issued in *Configuration* mode. You can access Config mode by entering **configure terminal** at the command prompt. You can exit your current command mode and return to a lower-level command mode at any time by entering **exit** at the command prompt.

The following sections describes how to access each command mode, the command prompt for each mode, and links to its available commands:

- [Enable Mode on page 7](#)
- [Config Mode on page 8](#)

Enable Mode

On logging onto the Mobility Conductor, the user mode is presented.

The command prompt for a CLI session in enable mode is a pound (**#**) symbol:

```
(host) [mynode] #
```

To view a list of commands available in enable mode, access the CLI in enable mode and enter a question mark (?):

```
(host) [mynode]#?
```

Some top-level commands have different sets of sub-commands available in Enable or Config mode. To view a list of available sub-commands in Enable mode, access the CLI in Enable mode, enter the top

level command, then enter a question mark (?). For example, the following example shows which aaa commands are available in Enable mode:

```
(host) [mynode]#aaa ?
authentication      Authentication
inservice           Bring authentication server into service
ipv6                Internet Protocol Version 6
query-user          Query User
test-server         Test authentication server
user                User commands
```

Config Mode

To move from enable mode to config mode, enter the command **config terminal**. Users in config mode may return to enable mode at any time by entering the command **exit**.

When you are in config mode, **(config)** appears before the # prompt:

```
(host) [mynode] (config) #
```

Some top-level commands have different sets of sub-commands available in the Enable or Config mode. To view a list of available sub-commands in the Config mode, access the CLI in the Config mode, enter the top level command, then enter a question mark (?). For example, the following example shows which **aaa** commands are available in the Config mode:

```
(host) [mynode] (config) #aaa ?
alias-group          Configure an Alias Group
auth-survivability   Configure Auth Survivability
auth-trace           Set parameters for debug tracing in AUTH (light weight
tracing)
authentication       Authentication
authentication-server Authentication Servers
bandwidth-contract   Configure bandwidth contract (256 Kbps - 2 Gbps)
derivation-rules     Configure rules to derive user role or vlan
dns-query-interval   Set DNS query interval
log                  Enable debugging on per-user basis
password-policy      Password policy for locally configured management users
profile              Configure an AAA Profile
radius-attributes    Configure RADIUS attribute
rfc-3576-server      Configure an RFC 3576 Server
server-group         Configure a Server Group
tacacs-accounting    Configure accounting
timers               Configure authentication timers
user                 User commands
xml-api              External XML API server
```

Configuration Sub-modes

Some Config mode commands can enter you into a sub-mode with a limited number of available commands specific to that mode. When you are in a configuration sub-mode, the (config) that appears before the command prompt will change to indicate your current mode; e.g (config-submode).

You can exit a sub-command mode and return to the basic configuration mode at any time by entering the [exit](#) command.

Saving Configuration Changes

Mobility Conductor has the running configuration images. The *running-config* holds the current controller configuration, including all pending changes which have yet to be saved. To view the running-config, use the following command:

```
(host) [mynode]# show running-config
```

When you make configuration changes via the CLI, those changes affect the current running configuration only. If the changes are not saved, they will be lost after the Mobility Conductor reboots. To save your configuration changes so they are retained after the Mobility Conductor reboots, use the following command in the enable or config mode:

```
(host) ^[mynode]# write memory
Saving Configuration...
Saved Configuration
```

The running configuration can also be saved to a file or sent to a TFTP server for backup or transfer to another system.

The ^ indicator appears between the (host) and [node] portions of the command prompt if the configuration contains unsaved changes. ArubaOS includes the following command prompts:

- (host) ^[mynode] – This indicates unsaved configuration.
- (host) *[mynode] – This indicates available crash information.
- (host) [mynode] – This indicates a saved configuration.

Commands That Reset the Mobility Conductor or AP

If you use the CLI to modify a currently provisioned and running radio profile, those changes take place immediately; you do not reboot the Mobility Conductor or the AP for the changes to affect the current running configuration. Certain commands, however, automatically force the Mobility Conductor or AP to reboot. You may want to consider current network loads and conditions before issuing these commands, as they may cause a momentary disruption in service as the unit resets. Note also that changing the **lms-ip** parameter in an AP system profile associated with an AP group will cause all APs in that AP group to reboot.

Table 1: *Reset Commands*

Commands that Reset an AP	Commands that Reset a Mobility Conductor
<ul style="list-style-type: none">▪ ap-regroup▪ ap-rename▪ apboot▪ provision-ap▪ ap wired-ap-profile {default <profile-name>} forward-mode {bridge split-tunnel tunnel}▪ wlan virtual-ap <profile-name> {aaa-profile <profile-name> forward-mode {tunnel bridge split-tunnel decrypt-tunnel} ssid-profile <profile-name> vlan <vlan>...}	<ul style="list-style-type: none">▪ reload

Commands that Reset an AP	Commands that Reset a Mobility Conductor
<ul style="list-style-type: none"> ▪ <code>ap system-profile <profile-name> {bootstrap-threshold <number> lms-ip <ipaddr> }</code> ▪ <code>wlan ssid-profile <profile-name> {battery-boost deny-bcast essid opmode strict-svp wepkey1 <key> wepkey2 <key> wepkey3 <key> wepkey4 <key> weptxkey <index> wmm wmm-be-dscp <best-effort> wmm-bk-dscp <background> wmm-ts-min-inact-int <milliseconds> wmm-vi-dscp <video> wmm-vo-dscp <voice> wpa-hexkey <psk> wpa-passphrase <string> }</code> ▪ <code>wlan dot11k <profile-name> {bcn-measurement-mode dot11k-enable force-dissasoc }</code> 	

Typographic Conventions

The following conventions are used throughout this manual to emphasize important concepts:

Table 2: Text Conventions

Type Style	Description
<i>Italics</i>	This style is used to emphasize important terms and to mark the titles of books.
Boldface	This style is used to emphasize command names and parameter options when mentioned in the text.
Commands	This fixed-width font depicts command syntax and examples of commands and command output.
<angle brackets>	In the command syntax, text within angle brackets represents items that you should replace with information appropriate to your specific situation. For example: ping <ipaddr> In this example, you would type “ping” at the system prompt exactly as shown, followed by the IP address of the system to which ICMP echo packets are to be sent. Do not type the angle brackets.
[square brackets]	In the command syntax, items enclosed in brackets are optional. Do not type the brackets.
{Item_A Item_B}	In the command examples, single items within curled braces and separated by a vertical bar represent the available choices. Enter only one choice. Do not type the braces or bars.

Type Style	Description
<code>{ap-name <ap-name>} {ipaddr <ip-addr>}</code>	Two items within curled braces indicate that both parameters must be entered together. If two or more sets of curled braces are separated by a vertical bar, like in the example to the left, enter only one choice Do not type the braces or bars.

Command Line Editing

The system records your most recently entered commands. You can review the history of your actions, or reissue a recent command easily, without having to retype it.

To view items in the command history, use the *up* arrow key to move back through the list and the *down* arrow key to move forward. To reissue a specific command, press **Enter** when the command appears in the command history. You can even use the command line editing feature to make changes to the command prior to entering it. The command line editing feature allows you to make corrections or changes to a command without retyping. [Table 3](#) lists the editing controls. To use key shortcuts, press and hold the **Ctrl** button while you press a letter key.

Table 3: Line Editing Keys

Key	Effect	Description
Ctrl A	Home	Move the cursor to the beginning of the line.
Ctrl B or the left arrow	Back	Move the cursor one character left.
Ctrl D	Delete Right	Delete the character to the right of the cursor.
Ctrl E	End	Move the cursor to the end of the line.
Ctrl F or the right arrow	Forward	Move the cursor one character right.
Ctrl K	Delete Right	Delete all characters to the right of the cursor.
Ctrl N or the down arrow	Next	Display the next command in the command history.
Ctrl P or up arrow	Previous	Display the previous command in the command history.
Ctrl T	Transpose	Swap the character to the left of the cursor with the character to the right of the cursor.
Ctrl U	Clear	Clear the line.
Ctrl W	Delete Word	Delete the characters from the cursor up to and including the first space encountered.
Ctrl X	Delete Left	Delete all characters to the left of the cursor.

Specifying Addresses and Identifiers in Commands

This section describes addresses and other identifiers that you can reference in CLI commands.

Table 4: *Addresses and Identifiers*

Address or Identifier	Description
IP address	For any command that requires an IP address to specify a network entity, use IPv4 network address format in the conventional dotted decimal notation (for example, 10.4.1.258).
Netmask address	For subnet addresses, specify a netmask in dotted decimal notation (for example, 255.255.255.0).
MAC address	For any command that requires a device's hardware address, use the hexadecimal format (for example, 00:05:4e:50:14:aa).
SSID	A unique character string (sometimes referred to as a network name), consisting of not more than 32 characters. The SSID is case-sensitive (for example, WLAN-01).
BSSID	This entry is the unique hard-wireless MAC address of the AP. A unique BSSID applies to each frequency— 802.11a and 802.11g— used from the AP. Use the same format as that of a MAC address.
ESSID	The unique logical name of a wireless network. If the ESSID includes spaces, you must enclose the name in quotation marks.
Fast Ethernet or Gigabit Ethernet interface	Any command that references a Fast Ethernet or Gigabit Ethernet interface requires that you specify the corresponding port on the managed device in the format <slot>/<module>/<port>: Use the show port status command to obtain the interface information currently available from a managed device.

Terminology Change

As part of advancing HPE's commitment to racial justice, we are taking a much-needed step in overhauling HPE engineering terminology to reflect our belief system of diversity and inclusion. Some legacy products and publications may continue to include terminology that seemingly evokes bias against specific groups of people. Such content is not representative of our HPE culture and moving forward, Aruba will replace racially insensitive terms and instead use the following new language:

Usage	Old Language	New Language
Campus Access Points + Controllers	Master-Slave	Conductor-Member
Instant Access Points	Master-Slave	Conductor-Member
Switch Stack	Master-Slave	Conductor-Member
Wireless LAN Controller	Mobility Master	Mobility Conductor
Firewall Configuration	Blacklist, Whitelist	Denylist, Allowlist
Types of Hackers	Black Hat, White Hat	Unethical, Ethical

aaa alias-group

```
aaa alias-group <ag-name>
  clone <group>
  no ...
  set
    vlan
      condition {ssid | location} equals <operand> set-value <set-value-string>
```

Description

This command configures a AAA alias with set of VLAN derivation rules that could speed up user rule derivation processing for deployments with a very large number of UDRs.

Parameter	Description
<ag-name>	Name of the alias group.
clone <group>	Copy data from another alias group.
no	Delete command.
set	Configure rules to derive role or VLAN.
vlan	Configure rule to set VLAN.
condition	Select one of the following condition to be matched: <ul style="list-style-type: none">▪ ssid : ESSID of the access point.▪ location : user location (ap name)
equals <operand>	Check if condition set equals the operand value.
set-value <set-value-string>	Specify the value that the role or VLAN should be set to.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa authentication captive-portal

```
aaa authentication captive-portal <profile>
  apple-cna-bypass
  ap-mac-in-redirectation-url
  auth-protocol mschapv2|pap|chap
  black-list/deny-list <black-list>/<deny-list>
  clone <source-profile>
  default-guest-role <role>
  default-role <role>
  enable-welcome-page
  guest-logon
  ip-addr-in-redirectation <ipaddr>
  login-page <url>
  logon-wait {cpu-threshold <percent>}|{maximum-delay <seconds>}|{minimum-delay
  <seconds>}
  logout-popup-window
  max-authentication-failures <number>
  no ...
  protocol-http
  proxy <ipaddr> port <port>
  redirect-pause <seconds>
  redirect-url <url>
  server-group <group-name>
  show-acceptable-use-policy
  show-fqdn
  single-session
  switchip-in-redirectation-url
  url-hash-key <key>
  user-idle-timeout
  user-logon
  user-vlan-in-redirectation-url
  welcome-page <url>
  white-list/allow-list <white-list>/<allow-list>
```

Description

This command configures the Captive Portal authentication profile in the base operating system or with the PEFNG license installed. When you configure the profile in the base operating system, the name of the profile must be entered for the initial role in the AAA profile. Also, when you configure the profile in the base operating system, you cannot define the default-role.

Starting from ArubaOS 8.7.0.0, captive portal authentication is supported for VAPs in the bridge forwarding mode. Only the following parameters of the `aaa authentication captive-portal` command will be supported in the bridge forwarding mode:

- `ap-mac-in-redirectation-url`
- `ip-addr-in-redirectation-url`
- `login-page`
- `switchip-in-redirectation-url`
- `url-hash-key`
- `user-vlan-in-redirectation-url`

Parameter	Description
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters. default
apple-cna-bypass	Enable this knob to bypass Apple CNA on iOS devices such as iPad, iPhone, and iPod. You need to perform Captive Portal authentication from browser.
authentication-protocol chap mschapv2 pap	This parameter specifies the type of authentication required by this profile, PAP is the default authentication type. mschapv2, pap, chap pap
ap-mac-in-redirection-url	This parameter adds the AP's MAC address in the redirection URL. disabled
black-list/deny-list	Name of an existing blacklist/denylist on an IPv4 or IPv6 network destination. The blacklist/denylist contains websites (unauthenticated) that a guest cannot access. Specify a netdestination host or subnet to add that netdestination to the captive portal blacklist/denylist. If you have not yet defined a netdestination, use the netdestination command to define a destination host or subnet before you add it to the blacklist/denylist.
clone	Name of an existing Captive Portal profile from which parameter values are copied.
default-guest-role	Role assigned to guest. guest
default-role <role>	Role assigned to the Captive Portal user when that user logs in. When both user and guest logons are enabled, the default role applies to the user logon; users logging in using the guest interface are assigned the guest role. guest
enable-welcome-page	Displays the configured welcome page before the user is redirected to their original URL. If this option is disabled, redirection to the web URL happens immediately after the user logs in. enabled
guest-logon	Enables Captive Portal logon without authentication. disabled
ipaddr-in-redirection-url	Sends the interface IP address of the managed device in the redirection URL when external captive portal servers are used. An external captive portal server can determine the managed device from which a request originated by parsing the switchip variable in the URL.
login-page <url>	URL of the page that appears for the user logon. This can be set to any URL.

Parameter	Description
logon-wait	Configure parameters for the logon wait interval. 1-100 60
cpu-threshold <percent>	CPU utilization percentage above which the logon wait interval is applied when presenting the user with the logon page. 1-100 60
maximum-delay <seconds>	Maximum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high. This works in conjunction with the Logon wait CPU utilization threshold parameter. 1-10 10
minimum-delay <seconds>	Minimum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high. This works in conjunction with the Logon wait CPU utilization threshold parameter. 1-10 5
logout-popup-window	Enables a pop-up window with the Logout link that allows the user to log out. If this option is disabled, the user remains logged in until the user timeout period has elapsed or the station reloads. enabled
max-authentication-failures <number>	Maximum number of authentication failures before the user is blacklisted/denylisted. 0-10 0
no	Negates any configured parameter.
protocol-http	Use HTTP protocol on redirection to the Captive Portal page. If you use this option, modify the captive portal policy to allow HTTP traffic. disabled
proxy	Update IP address of the proxy host.
redirect-pause <secs>	Time, in seconds, that the system remains in the initial welcome page before redirecting the user to the final web URL. If set to 0, the welcome page displays until the user clicks on the indicated link. 1-60 10
redirect-url <url>	URL to which an authenticated user will be directed. This parameter must be an absolute URL that begins with either http:// or https:// .

Parameter	Description
<code>server-group <group-name></code>	Name of the group of servers used to authenticate Captive Portal users.
<code>show-fqdn</code>	Allows the user to see and select the FQDN on the login page. The FQDNs shown are specified when configuring individual servers for the server group used with captive portal authentication. disabled
<code>single-session</code>	Allows only one active user session at a time. disabled
<code>show-acceptable-use-policy</code>	Show the acceptable use policy page before the login page. disabled
<code>switchip-in-redirectation-url</code>	Sends the IP address of the managed device in the redirection URL when external captive portal servers are used. An external captive portal server can determine the managed device from which a request originated by parsing the switchip variable in the URL. disabled
<code>url-hash-key <key></code>	Issue this command to hash the redirection URL using the specified key. disabled
<code>user-idle-timeout</code>	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. Valid range is 30-43200 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used. disabled
<code>user-logon</code>	Enables Captive Portal with authentication of user credentials. enabled
<code>user-vlan-in-redirectation-url</code>	Add the user VLAN in the redirection URL. disabled
<code>welcome-page <url></code>	URL of the page that appears after logon and before redirection to the web URL. This can be set to any URL.
<code>white-list/allow-list</code>	Name of an existing whitelist/allowlist on an IPv4 or IPv6 network destination. The whitelist/allowlist contains authenticated websites that a guest can access. If you have not yet defined a netdestination, use the netdestination command to define a destination host or subnet before you add it to the whitelist/allowlist.

Example

The following example configures a Captive Portal authentication profile that authenticates users against the internal database. Users who are successfully authenticated are assigned the auth-guest role.

To create the auth-guest user role shown in this example, the PEFNG license must be installed in the Mobility Conductor.

```
(host)^[md] (config) #aaa authentication captive-portal guestnet
(host) ^[md] (Captive Portal Authentication Profile "guestnet") #default-role
auth-guest
(host) ^[md] (Captive Portal Authentication Profile "guestnet") #user-logon
(host) ^[md] (Captive Portal Authentication Profile "guestnet") #no guest-logon

```

Description

This command configures the 802.1X authentication profile and allows you to enable and configure machine authentication and 802.1X termination on the managed device (also called AAA FastConnect). In the AAA profile, specify the 802.1X authentication profile, the default role for authenticated users, and the server group for the authentication.

Parameter	Description
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters. default
clear	Clear the Cached PMK, Role and VLAN entries. This command is available in enable mode only.
countermeasures	Scans for message integrity code failures in traffic received from clients. If there are more than 2 message integrity code failures within 60 seconds, the AP is shut down for 60 seconds. This option is intended to slow down an attacker who is making a large number of forgery attempts in a short time. disabled
ca-cert <certificate>	CA certificate for client authentication. The CA certificate needs to be loaded in the Mobility Conductor.
ca-cert-name	Name of the CA certificate.
cert-cn-lookup	If you use client certificates for user authentication, enable this option to verify that the CN of the certificate exists in the server. This parameter is disabled by default.
delete-keycache	Delete the key cache entry when the user entry is deleted. disabled
eapol-logoff	Enables handling of EAPOL-LOGOFF messages. disabled
enforce-suite-b-128	Configure Suite-B 128 bit or more security level authentication enforcement. disabled
enforce-suite-b-192	Configure Suite-B 192 bit or more security level authentication enforcement disabled
framed-mtu <MTU>	Sets the framed MTU attribute sent to the authentication server. 500-1500 1100

Parameter	Description
heldstate-bypass-counter <number>	This parameter is applicable when 802.1X authentication is terminated on the Mobility Conductor, also known as AAA FastConnect. Number of consecutive authentication failures which, when reached, causes the Mobility Conductor to not respond to authentication requests from a client while the Mobility Conductor is in a held state after the authentication failure. Until this number is reached, the Mobility Conductor responds to authentication requests from the client even while the Mobility Conductor is in its held state. 0-3 0
ignore-eap-id-match	Ignore EAP ID during negotiation. disabled
ignore-eapol-start-afterauthentication	Ignores EAPOL-START messages after authentication. disabled
key-cache clear	Clears the Cached PMK, Role and VLAN.
machine-authentication	This parameter is applicable in Windows environments only. These parameters set machine authentication. This parameter requires the PEFNG license.
blacklist-on-failure / denylist-on-failure	Blocks the client if machine authentication fails. disabled
cache-timeout <hours>	The timeout, in hours, for machine authentication. 1-1000 24
enable	Select this option to enforce machine authentication before user authentication. If selected, either the machine-default-role or the user-default-role is assigned to the user, depending on which authentication is successful. disabled
machine-default-role <role>	Default role assigned to the user after completing only machine authentication. guest
user-default-role <role>	Default role assigned to the user after 802.1X authentication. guest

Parameter	Description
<code>max-authentication-failures <number></code>	<p>Number of times a user can try to login with wrong credentials after which the user is blocked as a security threat. Set to 0 to disable denylisting, otherwise enter a non-zero integer to block the user after the specified number of failures.</p> <p>0-5 0</p>
<code>max-requests <number></code>	<p>Maximum number of times ID requests are sent to the client.</p> <p>1-10 5</p>
<code>multicast-key rotation</code>	<p>Enables multicast key rotation</p> <p>disabled</p>
<code>no</code>	<p>Negates any configured parameter.</p>
<code>opp-key-caching</code>	<p>Enables a cached PMK derived with a client and an associated AP to be used when the client roams to a new AP. This allows clients faster roaming without a full 802.1X authentication. Make sure that the wireless client (the 802.1X supplicant) supports this feature. If the client does not support this feature, the client will attempt to renegotiate the key whenever it roams to a new AP. As a result, the key cached on the managed device can be out of sync with the key used by the client.</p> <p>enabled</p>
<code>reauth-max <number></code>	<p>Maximum number of reauthentication attempts.</p> <p>1-10 3</p>
<code>reauth-server-termination-action</code>	<p>Specifies the termination-action attribute from the server.</p>
<code>reauthentication</code>	<p>Select this option to force the client to do a 802.1X reauthentication after the expiration of the default timer for reauthentication. (The default value of the timer is 24 hours.) If the user fails to reauthenticate with valid credentials, the state of the user is cleared.</p> <p>If derivation rules are used to classify 802.1X-authenticated users, then the reauthentication timer per role overrides this setting.</p> <p>disabled</p>
<code>reload-cert</code>	<p>Reload certificate for 802.1X termination. This command is available in enable mode only.</p>

Parameter	Description
server	Sets options for sending authentication requests to the authentication server group.
server-retry <number>	Maximum number of authentication requests that are sent to server group. 0-5 3
server-retry-period <seconds>	Server group retry interval, in seconds. 2-65535 5
server-cert <certificate>	Server certificate used by the managed device to authenticate itself to the client.
termination	Sets options for terminating 802.1X authentication on the managed device.
eap-type <type>	The EAP method, either EAP-PEAP or EAP-TLS. eap-peap, eap-tls eap-peap
enable	Enables 802.1X termination on the managed device. disabled
enable-token -caching	If you select EAP-GTC as the inner EAP method, you can enable the Mobility Conductor to cache the username and password of each authenticated user. The Mobility Conductor continues to reauthenticate users with the remote authentication server, however, if the authentication server is not available, the Mobility Conductor will inspect its cached credentials to reauthenticate users. disabled
inner-eap-type eap-gtc eap-mschapv2	When EAP-PEAP is the EAP method, one of the following inner EAP types is used: EAP-GTC: Described in RFC 2284, this EAP method permits the transfer of unencrypted usernames and passwords from client to server. The main uses for EAP-GTC are one-time token cards such as SecureID and the use of LDAP or RADIUS as the user authentication server. You can also enable caching of user credentials on the Mobility Conductor as a backup to an external authentication server. EAP-MSCHAPv2: Described in RFC 2759, this EAP method is widely supported by Microsoft clients. eap-gtc, eap- mschapv2 eap-mschapv2

Parameter	Description
token-caching-period <hours>	If you select EAP-GTC as the inner EAP method, you can specify the timeout period, in hours, for the cached information. 24
timer	Sets timer options for 802.1X authentication:
idrequest-period <seconds>	Interval, in seconds, between identity request retries. 1-65535 5
keycache-tmout	Set the per BSSID PMKSA cache interval. Cache is deleted within 2 hours of the interval. 1-2000 8
mkey-rotation-period <seconds>	Interval, in seconds, between multicast key rotation. 60-864000 1800
quiet-period <seconds>	Interval, in seconds, following failed authentication. 1-65535 30
reauth-period <seconds>	Interval, in seconds, between reauthentication attempts, or specify server to use the server-provided reauthentication period. 60-864000 86400
ukey-rotation-period <seconds>	Interval, in seconds, between unicast key rotation. 60-86400 900
wpa-groupkey-delay <milliseconds>	Interval, in milliseconds, between unicast and multicast key exchanges. 0-2000 0
wpa-key-period <milliseconds>	Interval, in milliseconds, between each WPA key exchange. 10-5000 1000
wpa2-key-delay <milliseconds>	Set the delay between EAP-Success and unicast key exchange.

Parameter	Description
	1-2000 0
<code>tls-guest-access</code>	Enables guest access for EAP-TLS users with valid certificates. disabled
<code>tls-guest-role <role></code>	User role assigned to EAP-TLS guest. This parameter requires the PEFNG license. guest
<code>unicast-keyrotation</code>	Enables unicast key rotation. disabled
<code>use-session-key</code>	Use RADIUS session key as the unicast WEP key. disabled
<code>use-static-key</code>	Use static key as the unicast or multicast WEP key. disabled
<code>validate-pmkid</code>	This parameter instructs the Mobility Conductor to check the PMK ID sent by the client. When this option is enabled, the client must send a PMK ID in the associate or reassociate frame to indicate that it supports OKC or PMK caching; otherwise, full 802.1X authentication takes place. (This feature is optional, since most clients that support OKC and PMK caching do not send the PMKID in their association request.) disabled
<code>wep-key-retries <number></code>	Number of times WPA or WPA2 key messages are retried. 1-3 2
<code>wep-key-size</code>	Dynamic WEP key size, either 40 or 128 bits. 128
<code>wpa-fast-handover</code>	Enables WPA-fast-handover. This is only applicable for phones that support WPA and fast handover. disabled
<code>wpa-key-retries</code>	Set the number of times WPA or WPA2 Key Messages are retried. The supported range is 1-10 retries, and the default value is 3.
<code>xSec-mtu <mtu></code>	Sets the size of the MTU for xSec. 1024-1500 1300

Examples

The following example enables authentication of the user's client device before user authentication. If machine authentication fails but user authentication succeeds, the user is assigned the restricted guest role:

```
(host) ^[md] (config) #aaa authentication dot1x dot1x
(host) ^[md] (802.1X Authentication Profile "dot1x") machine-authentication enable
(host) ^[md] (802.1X Authentication Profile "dot1x") machine-authentication
machine-default-role computer
(host) ^[md] (802.1X Authentication Profile "dot1x") machine-authentication user-
default-role guest
```

The following example configures an 802.1X profile that terminates authentication on the managed device, where the user authentication is performed with the internal database of the managed device or to a "backend" non-802.1X server:

```
(host) ^[md] (config) #aaa authentication dot1x dot1x
(host) ^[md] (802.1X Authentication Profile "dot1x") #termination enable
```

Command History

ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system. The voice-aware parameter requires the PEFNG license.	Config mode on Mobility Conductor.

aaa authentication mac

```
aaa authentication mac <profile>
  case upper|lower
  clone <profile>
  delimiter {colon|dash|none}
  max-authentication-failures <number>
  no ...
  reauthentication
  timer reauth period {<ra-period>|server}
```

Description

This command configures the MAC authentication profile, which configures authentication of devices based on their physical MAC address. MAC-based authentication is often used to authenticate and allow network access through certain devices while denying access to all other devices. Users may be required to authenticate themselves using other methods, depending on the network privileges.

Parameter	Description
<profile>	Name that identifies an instance of the profile. The name must be 1-63 characters.
case	The case (upper or lower) used in the MAC string sent in the authentication request. If there is no delimiter configured, the MAC address in lower case is sent in the format xxxxxxxxxxxx, while the MAC address in upper case is sent in the format XXXXXXXXXXXX. upper, lower lower
clone <profile>	Name of an existing MAC profile from which parameter values are copied.
delimiter	Delimiter (colon, dash, none, oui-nic) used in the MAC string. colon, dash, none, oui-nic none
max-authentication-failures <number>	Number of times a client can fail to authenticate before it is blocked. A value of 0 disables blacklisting/denylisting. 0-10 0
no	Negates any configured parameter.
reauthentication	Use this parameter to enable or disable reauthentication. disabled
timer reauth period <ra-period> server	<ra-period> specifies the period between reauthentication attempts in seconds. The server parameter specifies the server-provided reauthentication interval. 60-86400 86400

Example

The following example configures a MAC authentication profile to block client devices that fail to authenticate.

```
(host) ^[md] (config) #aaa authentication mac mac-denylist
(host) ^[md] (MAC Authentication Profile "mac-denylist") #max-authentication-
failures 3
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

aaa authentication mgmt

```
aaa authentication mgmt
  default-role {ap-provisioning|guest-provisioning|location-api-mgmt|nbapi-mgmt|network-
  operations|no-access|read-only|root|standard}
  enable
  mchapv2
  no ...
  server-group <group>
```

Description

This command configures authentication for administrative users. If you enable authentication with this command, users configured with the `mgmt-user` command must be authenticated using the specified `server-group`.

You can configure the management authentication profile in the base operating system or with the PEFNG license installed.

Syntax

Parameter	Description
<code>default-role</code>	Select a predefined management role to assign to authenticated administrative users:
<code>ap-provisioning</code>	AP provisioning role.
<code>guest-provisioning</code>	Guest provisioning role.
<code>location-api-mgmt</code>	Location API management role.
<code>nbapi-mgmt</code>	NBAPI management role.
<code>network-operations</code>	Network operator role.
<code>read-only</code>	Read-only role.
<code>root</code>	Default role or superuser role.
<code>standard</code>	Standard role
<code>enable</code>	Enables authentication for administrative users. disabled
<code>mchapv2</code>	Enable MSCHAPv2. disabled
<code>no</code>	Negates any configured parameter.
<code>server-group <group></code>	Name of the group of servers used to authenticate administrative users.

Example

The following example configures a management authentication profile that authenticates users against the internal database of the Mobility Conductor. Users who are successfully authenticated are assigned the read-only role.

```
(host) [mynode] (config) aaa authentication mgmt
default-role read-only
server-group internal
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The standard parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa authentication-server internal

```
aaa authentication-server internal
  use-local-switch
```

Description

This command specifies that the internal database on a managed device must be used for authenticating clients.

Parameter	Description
use-local-switch	Use the internal database on the local managed device. By default, the internal database on the Mobility Conductor is used for authentication.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor executed on the managed device node.

aaa auth-survivability

```
aaa auth-survivability
  cache-lifetime
  enable
  server-cert
```

Description

This command configures authentication survivability on a managed device.

Parameter	Description
cache-lifetime <hrs>	<p>This parameter specifies the lifetime in hours for the cached access credential in the local Survival Server. When the specified cache-lifetime expires, the cached access credential is deleted from the managed device.</p> <p>1-72 1</p>
enable	<p>This parameter controls whether to use the Survival Server when no other servers in the server group are in-service. This parameter also controls whether to store the user access credential in the Survival Server when it is authenticated by an external RADIUS or LDAP server in the server group. Authentication Survivability is enabled or disabled on each managed device. Authentication survivability will not activate if the Authentication Server Dead Time is configured as 0</p> <p>Disabled</p>
server-cert	<p>This parameter allows you to view the name of the server certificate used by the local Survival Server. The local Survival Server is provided with a default server certificate from AOS. The customer server certificate must be imported into the managed device first, and then you can assign the server certificate to the local Survival Server.</p> <p>NOTE: In the deployment environment, it is recommended that you switch to a customer server certificate.</p>

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa authentication-server ldap

```
aaa authentication-server ldap <server>
  admin-dn <name>
  admin-passwd <string>
  allow-clear-text
  authport <port>
  base-dn <name>
  chase-referrals
  clone <server>
  enable
  filter <filter>
  host <ipaddr>
  key-attribute <string>
  max-connection <number>
  no ...
  preferred-conn-type ldap-s|start-tls|clear-text
  timeout <seconds>
```

Description

This command configures an LDAP server. You configure a server before you can add it to one or more server groups. You create a server group for a specific type of authentication (see [aaa server-group on page 103](#)).

A maximum of 128 LDAP servers can be configured on the Mobility Conductor.

Parameter	Description
<server>	Name that identifies the server.
admin-dn <name>	DN for the admin user who has read or search privileges across all of the entries in the LDAP database (the user does not need write privileges but should be able to search the database and read attributes of other users in the database).
admin-passwd <string>	Password for the admin user.
allow-clear-text	Allows clear-text (unencrypted) communication with the LDAP server. Disabled
authport <port>	Port number used for authentication. Port 636 will be attempted for LDAP over SSL-LDAP, while port 389 will be attempted for SSL over LDAP, Start TLS operation and clear text. 1-65535 389
base-dn <name>	DN name of the node which contains the entire user database to use.
chase-referrals	Chase referrals anonymously.

Parameter	Description
<code>clone <server></code>	Name of an existing LDAP server configuration from which parameter values are copied.
<code>enable</code>	Enables the LDAP server.
<code>filter <filter></code>	Filter that should be applied to search of the user in the LDAP database. (objectclass=*)
<code>host <ip-addr></code>	IP address of the LDAP server, in dotted-decimal format.
<code>key-attribute <string></code>	Attribute that should be used as a key in search for the LDAP server. For PAP, the value is sAMAccountName. For EAP-TLS termination the value is userPrincipalName. sAMAccountName
<code>max-connection</code>	Maximum number of simultaneous non-admin connections to an LDAP server.
<code>no</code>	Negates any configured parameter.
<code>preferred-conn-type</code>	Preferred connection type. The default order of connection type is: 1. ldap-s 2. start-tls 3. clear-text The Mobility Conductor will first try to contact the LDAP server using the preferred connection type, and will only attempt to use a lower-priority connection type if the first attempt is not successful. You enable the allow-cleartext option before you select clear-text as the preferred connection type. If you set clear-text as the preferred connection type but do not allow clear-text, the Mobility Conductor will only use ldap-s or start-tls to contact the LDAP server. ldap-s, start-tls, clear-text ldap-s
<code>timeout <seconds></code>	Timeout period of a LDAP request, in seconds. 1-30 20

Example

The following command configures and enables an LDAP server:

```
(host) ^[md] (config) #aaa authentication-server ldap ldap1
(host) ^[md] (LDAP Server "ldap1") #host 10.1.1.243
(host) ^[md] (LDAP Server "ldap1") #base-dn cn=Users,dc=lm,dc=corp,dc=com
(host) ^[md] (LDAP Server "ldap1") #admin-dn cn=corp,cn=Users,dc=lm,dc=corp,dc=com
(host) ^[md] (LDAP Server "ldap1") #admin-passwd abc10
(host) ^[md] (LDAP Server "ldap1") #key-attribute sAMAccountName
(host) ^[md] (LDAP Server "ldap1") #filter (objectclass=*)
(host) ^[md] (LDAP Server "ldap1") #enable
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa authentication-server radius

```
aaa authentication-server radius <rad_server_name>
  acct-modifier <profile_name>
  acctport <port>
  authport <port>
  auth-modifier <profile_name>
  called-station-id type
    {ap-group | ap-macaddr | ap-name | ipaddr | macaddr | vlan-id}
    [delimiter {colon | dash | none}] [include-ssid {enable |disable}]
  clone <server>
  cppm username <username> password <password>
  enable
  enable-ipv6
  enable-radsec
  host <ipaddr>|<FQDN>
  key <psk>
  mac-delimiter [colon | dash | none | oui-nic]
  mac-lowercase
  nas-identifier <string>
  nas-ip <ipaddr>
  nas-ip6 <ipv6-address>
  no
  radsec-client-cert-name <name>
  radsec-port <radsec-port>
  radsec-trusted-cacert-name <radsec-trusted-ca>
  radsec-trusted-servercert-name <name>
  retransmit <number>
  service-type-framed-user
  source-interface vlan <vlan> ip6addr <ipv6addr>
  timeout <seconds>
  use-ip-for-calling-station
  use-md5
```

Description

This command configures a RADIUS server. You can configure a server before you can add it to one or more server groups. You can create a server group for a specific type of authentication (see [aaa server-group on page 103](#)).

Parameter	Description
<rad_server_name>	Name that identifies the server.
acct-modifier <profile_name>	Attributes modifier for accounting-request.
acctport <port>	Accounting port on the server. 1-65535 1813
authport <port>	Authentication port on the server. 1-65535 1812

Parameter	Description
<code>auth-modifier</code>	Attributes modifier for access-request.
<code>called-station-id type</code> { <code>ap-group</code> <code>ap-macaddr</code> <code>ap-name</code> <code>ipaddr</code> <code>macaddr</code> <code>vlan-id</code> }	Configure this parameter to be sent with the RADIUS attribute Called Station ID for authentication and accounting requests. The <code>called-station-id</code> parameter can be configured to include AP group, AP MAC address, AP name, Mobility Conductor IP, Mobility Conductor MAC address, or user vlan. The default value is Mobility Conductor MAC address. <code>macaddr</code>
<code>clone <server></code>	Name of an existing RADIUS server configuration from which parameter values are copied.
<code>c ppm username <username></code> <code>password <password></code>	Configure the ClearPass Policy Manager username and password. The Mobility Conductor authenticating to ClearPass Policy Manager is enhanced to use configurable username and password instead of support password. The support password is vulnerable to attacks as the server certificate presented by ClearPass Policy Manager server is not validated.
<code>enable</code>	Enables the RADIUS server.
<code>enable-ipv6</code>	Enables the RADIUS server in IPv6 mode.
<code>enable-radsec</code>	Enables RadSec for RADIUS data transport over TCP and TLS.
<code>host</code>	Identify the RADIUS server either by its IP address or FQDN.
<code><ipaddr></code>	IPv4 or IPv6 address of the RADIUS server.
<code><FQDN></code>	FQDN of the RADIUS server. The maximum supported length is 63 characters.
<code>key <psk></code>	Shared secret between the Mobility Conductor and the authentication server. The maximum length is 128 characters.
<code>mac-delimiter</code> [<code>colon</code> <code>dash</code> <code>none</code> <code>oui-nic</code>]	Send MAC address with user-defined delimiter. <code>none</code>
<code>mac-lowercase</code>	Send MAC addresses as lowercase.
<code>nas-identifier <string></code>	NAS identifier to use in RADIUS packets.
<code>nas-ip <ip-addr></code>	The NAS IP address to be sent in RADIUS packets from that server. If you define a local NAS IP setting using this command and also define a global NAS IP using the command <code>ip radius nas-ip <ip-addr></code> , the global NAS IP address takes precedence.
<code>nas-ip6 <ipv6-address></code>	NAS IPv6 address to send in RADIUS packets. You can configure a global NAS IPv6 address that the Mobility Conductor uses for communications with all RADIUS servers. If you do not configure a server-specific NAS IPv6, the global NAS IPv6 is used. To set the global NAS IPv6, enter the <code>ipv6 radius nas-ip6 <ipv6-address></code> command.

Parameter	Description
no	Negates any configured parameter.
radsec-client-cert <radsec-client-cert>	Configures a RadSec client certificate on the RADIUS server to identify and authenticate clients.
radsec-port <radsec-port>	Designates a RadSec port for RADIUS data transport. 1-65535 2083
radsec-trusted-cacert-name <radsec-trusted-ca>	Designates a CA to sign RadSec certificates.
radsec-trusted-servercert-name <radsec-trusted-ca>	Designates a trusted RadSec server certificate.
retransmit <number>	Maximum number of retries sent to the server by the Mobility Conductor before the server is marked as down. 0-3 3
service-type-framed-user	Send the service-type as FRAMED-USER instead of LOGIN-USER. This option is disabled by default. disabled
source-interface vlan <vlan> ip6addr <ip6addr>	This option associates a VLAN interface with the RADIUS server to allow the server-specific source interface to override the global configuration. <ul style="list-style-type: none"> ■ If you associate a Source Interface (by entering a VLAN number) with a configured server, then the source IP address of the packet will be that interface's IP address. ■ If you do not associate the Source Interface with a configured server (leave the field blank), then the IP address of the global Source Interface will be used. ■ If you want to configure an IPv6 address for the Source Interface, specify the IPv6 address for the <code>ip6addr</code> parameter.
timeout <seconds>	Maximum time, in seconds, that the Mobility Conductor waits before timing out the request and resending it. 1-30 5 Starting from ArubaOS 8.10.0.0, the range of the RADIUS server authentication timeout value is increased from 1-30 seconds to 1-120 seconds.
use-ip-for-calling-station	Use an IP address instead of a MAC address for calling station IDs. This option is disabled by default. disabled
use-md5	Use MD5 hash of cleartext password. disabled

Example

The following command configures and enables a RADIUS server:

```
(host) [md] (config) #aaa authentication-server radius radius
(host) [md] (RADIUS Server "radius") #host 10.1.1.244
(host) [md] (RADIUS Server "radius") #key qwERTyuIop
(host) [md] (RADIUS Server "radius") #enable
```

Command History

Release	Modification
ArubaOS 8.10.0.0	The range of the RADIUS server authentication timeout value was increased from 1-30 seconds to 1-120 seconds.
ArubaOS 8.1.0.0	The following parameters were added: <ul style="list-style-type: none">■ acct-modifier■ auth-modifier
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa authentication-server tacacs

```
aaa authentication-server tacacs <server>
  clone <source>
  enable
  host <host>
  key <psk>
  no ...
  retransmit <number>
  session-authorization
  source-interface
  tcp-port <port>
  timeout <seconds>
```

Description

This command configures a TACACS+ server. You can configure a server before you can add it to one or more server groups. You can create a server group for a specific type of authentication (see [aaa server-group on page 103](#)).

A maximum of 128 TACACS servers can be configured on the Mobility Conductor.

Parameter	Description
<server>	Name that identifies the server.
clone <source>	Name of an existing TACACS server configuration from which parameter values are copied.
enable	Enables the TACACS server.
host <host>	IPv4 or IPv6 address of the TACACS server.
key	Shared secret to authenticate communication between the TACACS client and server.
no	Negates any configured parameter.
retransmit <number>	Maximum number of times a request is retried. 0-3 3
session-authorization	Enables TACACS+ authorization. Session-authorization turns on the optional authorization session for admin users. disabled
source-interface	Select source address of outgoing TACACS requests to the server.
vlan <vlan_id>	Select VLAN of outgoing TACACS requests to the server. 1-4094
tcp-port <port>	TCP port used by the server. 1-65535 49

Parameter	Description
timeout <timeout>	Timeout period of a TACACS request, in seconds. 1-30 20

Example

The following command configures, enables a TACACS+ server and enables session authorization:

```
(host) ^[md] (config) #aaa authentication-server tacacs tacacs1
(host) ^[md] (TACACS Server "tacacs1")clone default
(host) ^[md] (TACACS Server "tacacs1")host 10.1.1.245
(host) ^[md] (TACACS Server "tacacs1")key qwERtyuIOp
(host) ^[md] (TACACS Server "tacacs1")enable
(host) ^[md] (TACACS Server "tacacs1")session-authorization
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>source-interface</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

aaa authentication-server windows

```
aaa authentication-server windows <windows_server_name>
  clone <source>
  domain <domain>
  enable
  host <ipaddr>
  no
```

Description

This command configures a windows server for stateful-NTLM authentication. You must define a Windows server before you can add it to one or more server groups. You create a server group for a specific type of authentication (see [aaa server-group on page 103](#)). Windows servers are used for stateful-NTLM authentication.

Parameter	Description
<windows_server_name>	Name of the windows server. You will use this name when you add the windows server to a server group.
clone <source>	Name of a Windows Server from which you want to make a copy.
domain <domain>	The Windows domain for the authentication server.
enable	Enables the Windows server.
host <ipaddr>	IP address of the Windows server.
no	Delete command.

Example

The following command configures and enables a windows server:

```
(host) ^[md] (config) #aaa authentication-server windows IAS_1
(host) ^[md] (Windows Server "IAS_1") #host 10.1.1.245
(host) ^[md] (Windows Server "IAS_1") #enable
```

aaa authentication stateful-dot1x

```
aaa authentication stateful-dot1x
  default-role <role>
  enable
  no ...
  server-group <group>
  timeout <seconds>
```

Description

This command configures 802.1X authentication for clients on non-Aruba APs. This command configures 802.1X authentication for clients on non-Aruba APs. The Mobility Conductor maintains user session state information for these clients.

Parameter	Description
default-role <role>	Role assigned to the 802.1X user upon login. The PEFNG license must be installed. guest
enable	Enables 802.1X authentication for clients on non-Aruba APs. Use <code>no enable</code> to disable stateful 802.1X authentication. enabled
no	Negates any configured parameter.
server-group <group>	Name of the group of RADIUS servers used to authenticate the 802.1X users.
timeout <seconds>	Timeout period, in seconds. 1-20 10

Example

The following command assigns the employee user role to clients who successfully authenticate with the server group corp-rad:

```
(host) ^[md] (config) aaa authentication stateful-dot1x
default-role employee
server-group corp-rad
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

aaa authentication stateful-dot1x clear

aaa authentication stateful-dot1x clear

Description

This command clears automatically-created control path entries for 802.1X users on non-Aruba APs. Run this command after changing the configuration of a RADIUS server in the server group configured with the `aaa authentication stateful-dot1x` command. This causes entries for the users to be created in the control path with the updated configuration information.

aaa authentication stateful-kerberos

```
aaa authentication stateful-kerberos <profile-name>
  clone
  default-role <role>
  no
  server-group <server-group>
  timeout <timeout>
```

Description

This command configures stateful Kerberos authentication.

Parameter	Description
clone <source>	Create a copy of an existing stateful Kerberos profile
default-role	Select an existing role to assign to authenticated users. guest
no	Negates any configured parameter.
server-group <server-group>	Name of a server group. default
timeout <timeout>	Amount of time, in seconds, before the request times out. 1-20 seconds 10 seconds

Example

```
(host) ^[md] (config) #aaa authentication stateful-kerberos default
(host) ^[md] (Stateful Kerberos Authentication Profile "default") #default-role
guest
(host) ^[md] (Stateful Kerberos Authentication Profile "default") #timeout 10
(host) ^[md] (Stateful Kerberos Authentication Profile "default") #server-group
internal
```

aaa authentication stateful-ntlm

```
aaa authentication stateful-ntlm <profile-name>
  clone
  default-role <role>
  enable
  no
  server-group <server-group>
  timeout <timeout>
```

Description

NTLM is a suite of Microsoft authentication and session security protocols. You can use a stateful NTLM authentication profile to configure a managed device to monitor the NTLM authentication messages between clients and an authentication server. The managed device can then use the information in the SMB headers to determine the username and IP address of the client, the server IP address and the current authentication status client. If the client successfully authenticates via an NTLM authentication server, the managed device can recognize that the client has been authenticated and assign that client a specified user role. When the user logs off or shuts down the client machine, the user will remain in the authenticated role until the user's authentication is aged out.

The stateful NTLM Authentication profile requires that you specify a server group which includes the servers performing NTLM authentication, and a default role to be assigned to authenticated users. For details on defining a windows server used for NTLM authentication, see [aaa authentication-server windows](#).

Parameter	Description
clone	Create a copy of an existing stateful NTLM profile
default-role	Select an existing role to assign to authenticated users. guest
enable	Enables stateful ntlm authentication profile for clients. Use <code>no enable</code> to disable stateful ntlm authentication. enabled
no	Negates any configured parameter.
server-group <server-group>	Name of a server group. default
timeout <timeout>	Amount of time, in seconds, before the request times out. 1-20 seconds 10 seconds

Example

The following example configures a stateful NTLM authentication profile that authenticates clients via the server group "Windows1." Users who are successfully authenticated are assigned the "guest2" role.

```
(host) ^[md] (config) #aaa authentication stateful-ntlm ntlm1
(host) ^[md] (Stateful NTLM Authentication Profile "ntlm1") #default-role guest2
(host) ^[md] (Stateful NTLM Authentication Profile "ntlm1") #server-group Windows1
```

aaa auth-trace

```
aaa auth-trace
  loglevel
```

Description

This command sets parameters for debug tracing in AUTH (light weight tracing).

Parameter	Description
loglevel	Specify the loglevel of syslogs that will be included in the trace.
alert	Trace all logs equal or higher than LOG_ALERT.
critical	Trace all logs equal or higher than LOG_CRIT.
debug	Trace all logs equal or higher than LOG_DEBUG.
emergency	Trace all logs equal or higher than LOG_EMERG.
error	Trace all logs equal or higher than LOG_ERR.
info	Trace all logs equal or higher than LOG_INFO.
notice	Trace all logs equal or higher than LOG_NOTICE.
warn	Trace all logs equal or higher than LOG_WARN.

aaa authentication via auth-profile

```
aaa authentication via auth-profile <profile>
  auth-protocol {mschapv2|pap}
  cert-cn-lookup
  client-cert-enable
  clone <source>
  default-role <default-role>
  desc <description>
  download-role
  encoding-format
  max-authentication-failures <max-authentication-failures>
  no
  pan-integration
  radius-accounting <server_group_name>
  rfc-3576-server <rfc-server>
  server-group <server-group>
```

Description

This command configures the VIA authentication profile and associates user roles to the authentication profile.

Parameter	Description
auth-protocol {mschapv2 pap}	Authentication protocol support for VIA authentication; MSCHAPv2 or PAP PAP
cert-cn-lookup	Check certificate CN against AAA server. Enabled
client-cert-enable	If selected, this option enables client certificate-based authentication for VPN profile download. Disabled
clone <source>	Name of an existing profile from which configuration values are copied.
default-role <default-role>	Name of the default VIA authentication profile.
desc <description>	Description of this profile for reference.
download-role	Name of the authentication profile to be downloaded from CPPM.
encoding-format	Specify one of the following encoding format type for the user credentials: <ul style="list-style-type: none">■ ANSI■ UTF-16■ UTF-8 The default type is UTF-8.

Parameter	Description
max-authentication-failures <max-authentication-failures>	Number of times VIA will prompt user to login due to incorrect credentials. After the maximum authentication attempts failures VIA will exit. 0
pan-integration	Requires IP mapping at Palo Alto Network.
radius-accounting <server_group_name>	Server group for RADIUS accounting.
rfc-3576-server <rfc-server>	Configures the RFC 3576 server.
server-group <server-group>	Server group against which the user is authenticated.

Example

```
(host) [md] (config) #aaa authentication via auth-profile default
(host) [md] (VIA Authentication Profile "default") #auth-protocol mschapv2
(host) [md] (VIA Authentication Profile "default") #default-role example-via-role

  whitelist/allowlist
  windows-credentials
```

Description

This command configures the VIA connection profile. A VIA connection profile contains settings required by VIA to establish a secure connection to the managed device. You can configure multiple VIA connection profiles. A VIA connection profile is always associated to a user role and all users belonging to that role will use the configured settings. If you do not assign a VIA connection profile to a user role, the default connection profile is used.

Parameter	Description
<code>admin-logoff-script</code>	Enables VIA logoff script. Disabled
<code>admin-logon-script</code>	Enables VIA logon script. Disabled
<code>allow-user-disconnect</code>	Enable or disable users to disconnect their VIA sessions. Enabled
<code>allow-whitelist-traffic / allow-allowlist-traffic</code>	If enabled, this feature will block network access until the VIA VPN connection is established. Disabled
<code>auth-profile <auth-profile></code>	This is the list of VIA authentication profiles that will be displayed to users in the VIA client.
<code>auth_domain_suffix</code>	Enables a domain suffix on VIA Authentication, so client credentials are sent as <i>domainname\username</i> instead of just <i>username</i> .
<code>auto-launch-supPLICANT</code>	Allows you to connect automatically to a configured WLAN network. Disabled
<code>auto-login</code>	Enable or disable VIA client to auto login and establish a secure connection to the managed device. Enabled
<code>auto-upgrade</code>	Enable or disable VIA client to automatically upgrade when an updated version of the client is available on the managed device. Enabled
<code>banner-message-reappear- timeout</code>	Timeout value, in minutes, after which the user session will end and the VIA Login banner message reappears. 1440
<code>block-destination-traffic- selector-ON</code>	Turn ON feature to block Destination Traffic .
<code>block-dest-traffic-address</code>	Destination Traffic selector.
<code>certificate-criteria</code>	Allows admin users to filter the certificates that can be used to establish the IPsec connection when a user certificate or EAP-TLS is used as the authentication method. Use the following certificate attributes or OIDs to set the certificate criteria:

Parameter	Description
	<ul style="list-style-type: none"> ■ commonName (OID 2.5.4.3) ■ organizationalUnitName (OID 2.5.4.11) ■ organizationName (OID 2.5.4.10) ■ subjectAltName (OID 2.5.29.17) ■ certificateIssuer (OID 2.5.29.29) ■ userPrincipalName (OID 1.3.6.1.4.1.311.20.2.3) ■ emailAddress (OID 1.2.840.113549.1.9.1) ■ friendlyName (OID 1.2.840.113549.1.9.20) <p>The maximum length is 256 characters. Each attribute or OID must be separated by a semicolon. If an attribute or OID contains any spaces, the entire string must be enclosed in quotation marks.</p>
client-logging	<p>Enable or disable VIA client to auto login and establish a secure connection to the managed device.</p> <p>Enabled</p>
client-netmask <client-netmask>	<p>The network mask that has to be set on the client after the VPN connection is established.</p> <p>255.255.255.255</p>
client-wlan-profile <client-wlan-profile>	<p>A list of VIA client WLAN profiles that needs to be pushed to the client machines that use Windows Zero Config to configure or manage their wireless networks.</p>
clone <source>	<p>Create a copy of connection profile from an another VIA connection profile.</p>
controllers-load-balance	<p>Enable this option to allow the VIA client to failover to the next available selected randomly from the list as configured in the VIA Servers option. If disabled, VIA will failover to the next in the sequence of ordered list of VIA servers.</p> <p>Disabled</p>
csec-gateway-url	<p>Specify the content security service providers URL here. You must provide a FQDN.</p>
csec-http-ports	<p>Specify the ports (separated by comma) that will be monitored by the content security service provider. Do not add space before or after the comma.</p>
dn-profile CN ORG OU Country	<p>Configure VIA dn profile.</p> <p>NOTE: If a hyphen is entered as an input after a parameter, the controller and VIA will then ignore that parameter. The following example ignores the OU parameter,</p> <pre>(host) [md] (config) #aaa authentication via connection-profile "via" (host) [md] (VIA Connection Profile "via") #dn-profile CN VIA-EXAMPLE.ACME.COM ORG IT OU - Country USA</pre>
dns-suffix-list <dns-suffix-list>	<p>The DNS suffix list (comma separated) that has be set on the client once the VPN connection is established.</p> <p>None</p>

Parameter	Description
<code>domain-preconnect</code>	Enable this option to allow users with lost or expired passwords to establish a VIA connection to corporate network. This option authenticates the user's device and establishes a VIA connection that allows users to reset credentials and continue with corporate access. Enabled
<code>dpc-generate-profile</code>	Optionally enable generating common profile in DPC is enabled.
<code>enable-csec</code>	Use this option to enable the content security service.
<code>enable-fips</code>	Enable the VIA FIPS module so VIA checks for FIPS compliance during startup. Disabled
<code>enable-supPLICant</code>	If enabled, VIA starts in bSec mode using L2 suite-b cryptography. This option is disabled by default. Disabled
<code>ext-download-url <ext-download-url></code>	End users will use this URL to download VIA on their computers.
<code>ike-policy <ike-policy></code>	List of IKE policies that the VIA Client has to use to connect to the managed device.
<code>ikev2-policy</code>	List of IKE V2 policies that the VIA Client has to use to connect to the managed device.
<code>ikev2-PROTO</code>	Enable this to use IKEv2 protocol to establish VIA sessions. Disabled
<code>ikev2auth</code>	Use this option to set the IKEv2 authentication method. By default user certificate is used for authentication. The other supported methods are EAP-MSCHAPv2, EAP-TLS. The EAP authentication is done on an external RADIUS server. User Certificates
<code>ipsec-cryptomap</code>	List of IPsec crypto maps that the VIA client uses to connect to the managed device. These IPsec Crypto Maps are configured in the CLI using the <code>crypto-local ipsec-map <ipsec-map-name></code> command.
<code>ipsecv2-cryptomap</code>	List of IPsec V2 crypto maps that the VIA client uses to connect to the managed device.
<code>l2-forwarding</code>	Enable this option to forward Layer-2 GRE tunnel.
<code>lockdown-all-settings</code>	Allows you to lock down all user-configured settings. Disabled
<code>max-reconnect-attempts <max-reconnect-attempts></code>	The maximum number of re-connection attempts by the VIA client due to authentication failures. 3
<code>max-timeout value <value></code>	The maximum time (minutes) allowed before the VIA session is disconnected.

Parameter	Description
	1440
minimized	Use this option to keep the VIA client on a Microsoft Windows operating system minimized to system tray.
mtu	MTU value in bytes for the VIA client. 576-5120 1452
ocsp-responder	OCSP Cert Verification.
enable	Enable or disable OCSP Cert verification.
fallback	Action taken when OCSP Cert verification result is unknown.
save-passwords	Enable or disable users to save passwords entered in VIA. Enabled
server	Configure VIA servers.
addr <addr>	This is the public IPv4 or IPv6 address or the DNS hostname of the managed device connected to VIA. Users connect to remote server using this IP address or the host name.
<internal-ip <internal-ip>	This is the IPv4 address of any of the VLAN interface IPv4 addresses that belongs to this managed device.
desc <description>	This is a human-readable description of the managed device.
split-tunneling	Enable or disable split tunneling. <ul style="list-style-type: none"> ■ If enabled, all traffic to the VIA tunneled networks will go through the managed device and the rest is just bridged directly on the client. ■ If disabled, all traffic will flow through the managed device. Off
suiteb-crypto	Use this option to enable Suite-B cryptography. See RFC 4869 for more information about Suite-B cryptography. Disabled
support-email	The support e-mail address to which VIA users will send client logs. None
tos-dscp {0-63}	Use this to mark IPsec packets with higher QoS/DSCP than Best Effort. The range is 0-63. 0
tunnel address <address>	A list of network destination (IP address and netmask) that the VIA client will tunnel through the managed device. All other network destinations will be reachable directly by the VIA client. Enter tunneled IP address and its netmask.
address <address>	
netmask <netmask>	

Parameter	Description
user-idle-timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used. Disabled
validate-server-cert	Enable or disable VIA from validating the server certificate presented by the managed device. Enabled
vis_cc_log_enable	Enable VIA CC compliance packet level logging.
whitelist addr /allowlist addr	Specify a hostname or IP address and network mask to define a whitelist/allowlist of users allowed to access the network if the allow-whitelist-traffic / allow-allowlist-traffic option is enabled. The maximum number of entries allowed is 16.
addr <addr>	Host name of IP address of a client
netmask <netmask>	Netmask, in dotted decimal format
description <description>	(Optional) description of the client
windows-credentials	Enable or disable the use of the Windows credentials to login to VIA. If enabled, the SSO feature can be utilized by remote users to connect to internal resources. Enabled

Example

The following example shows a simple VIA connection profile:

```
(host) [md] (config) #aaa authentication via connection-profile "via"
(host) [md] (VIA Connection Profile "via") #server addr 202.100.10.100 internal-ip
10.11.12.13 desc "VIA Primary" position 0
(host) [md] (VIA Connection Profile "via") #auth-profile "default" position 0
(host) [md] (VIA Connection Profile "via") #tunnel address 10.0.0.0 netmask
255.255.255.0
(host) [md] (VIA Connection Profile "via") #split-tunneling
(host) [md] (VIA Connection Profile "via") #windows-credentials
(host) [md] (VIA Connection Profile "via") #client-netmask 255.0.0.0
(host) [md] (VIA Connection Profile "via") #dns-suffix-list mycorp.com
(host) [md] (VIA Connection Profile "via") #dns-suffix-list example.com
(host) [md] (VIA Connection Profile "via") #support-email via-support@example.com
(host) [md] (VIA Connection Profile "via") #certificate-criteria
certificateIssuer="HPE Root CA"; 2.5.4.10=SmartCard;
emailAddress=support@example.com
```

The following CLI commands configure the **tos-dscp** parameter:

```
(host) [mynode] (config) #aaa authentication via connection-profile <profile-name>
(host) [mynode] (VIA Connection Profile "<profile-name>") #tos-dscp <0-63>
```

The following CLI commands configure IPv6 address of the managed device:

```
(host) [mynode] (config) #aaa authentication via connection-profile test
(host) [mynode] (VIA Connection Profile "test") #server addr 2001:1:2:2020::1
internal-ip 10.11.12.13 desc "VIA Primary" position 0
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The following terminologies are updated: <ul style="list-style-type: none">▪ All instances of <code>blacklist</code> have been replaced with <code>denylist</code>.▪ All instances of <code>whitelist</code> have been replaced with <code>allowlist</code>.
ArubaOS 8.7.0.0	The <code>addr</code> sub-parameter was modified to include IPv6 address.
ArubaOS 8.4.0.0	The <code>l2-forwarding</code> parameter was added.
ArubaOS 8.3.0.0	The <code>tos-dscp</code> parameter was added.
ArubaOS 8.1.0.0	The <code>certificate-criteria</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

aaa authentication via global-config

```
aaa authentication via global-config
no
ssl-fallback-enable
max-via-vpn-sessions
no max-via-vpn-sessions
```

Description

The global config option allows you to enable SSL fallback mode. If the SSL fallback mode is enabled, the VIA client will use SSL to create a secure connection.

Parameter	Description
no	Disables SSL fallback option.
ssl-fallback-enable	Use this option to enable an SSL fallback connection.
max-via-vpn-sessions	Sets the value of maximum concurrent VIA VPN sessions per user. Range: 1-32. Default: 0
no max-via-vpn-sessions	Resets the value of maximum concurrent VIA VPN sessions per user to 0.

Example

```
(host) [md] (config) #aaa authentication via global-config
(host) [md] (VIA Global Configuration) #max-via-vpn-sessions
<max-via-vpn-sessions> Maximum Concurrent VIA VPN Sessions Per User. Range: 1-32.
Default: 0 (Disabled).
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The max-via-vpn-sessions parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

aaa authentication via web-auth

```
aaa authentication via web-auth default
  auth-profile <auth-profile> position <position>
  clone <source>
  no
```

Description

A VIA web authentication profile contains an ordered list of VIA authentication profiles. The web authentication profile is used by end users to login to the VIA download page (<https://<server-IP-address>/via>) for downloading the VIA client. Only one VIA web authentication profile is available. If more than one VIA authentication profile is configured, users can view this list and select one during the client login.

Parameter	Description
auth-profile <auth-profile>	The name of the VIA authentication profile
position <position>	The position of the profile to specify the order of selection.
clone <source>	Duplicate an existing authentication profile.

Example

```
(host) [md] (config) #aaa authentication via web-auth default
(host) [md] (VIA Web Authentication "default") #auth-profile default position 0
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

aaa authentication vpn

```
aaa authentication vpn <profile-name>
  cert-cn-lookup
  clone <source>
  default-role <guest>
  export-route
  max-authentication-failures <number>
  no ...
  pan-integration
  radius-accounting
  server-group <group>
  user-idle-timeout
```

Description

This command configures VPN authentication settings.

Parameter	Description
<profile-name>	There are three VPN profiles: default , default-rap or default-cap . This allows users to use different AAA servers for VPN, Remote AP and Campus AP clients. The default and default-rap profiles are configurable. The default-cap profile is not configurable and is predefined with the default settings.
cert-cn-lookup	If you use client certificates for user authentication, enable this option to verify that the CN of the certificate exists in the server. This parameter is enabled by default in the default-cap and default-rap VPN profiles, and disabled by default on all other VPN profiles.
clone <source>	Copies data from another VPN authentication profile. Source is the profile name from which the data is copied.
default-role <role>	Role assigned to the VPN user upon login. This parameter requires PEF for VPN Users license. guest
export-route	Exports a VPN IP address as a route to the external world. enabled
max-authentication-failures <number>	Maximum number of authentication failures before the user is blacklisted/denylister. The supported range is 1-10 failures. A value of 0 disables blacklisting/denylister. This parameter requires the RFProtect license. 0
no	Negates any configured parameter.
pan-integration	Require IP mapping at Palo Alto Networks firewalls. disabled

Parameter	Description
radius-accounting	Configure server group for RADIUS accounting
server-group <group>	Name of the group of servers used to authenticate VPN users. internal
user-idle-timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.

Usage Guidelines

This command configures VPN authentication settings for VPN, Remote AP and Campus AP clients. Use the `vpdn group` command to configure L2TP or IPsec or a PPTP VPN connection.

Example

The following command configures VPN authentication settings for the default-rap profile:

```
(host) ^[md] (config) #aaa authentication vpn default-rap
(host) ^[md] (VPN Authentication Profile "default-rap")default-role guest
(host) ^[md] (VPN Authentication Profile "default-rap")clone default
(host) ^[md] (VPN Authentication Profile "default-rap")max-authentication-failures
0
(host) ^[md] (VPN Authentication Profile "default-rap")server-group vpn-server-
group
```

The following message appears when a user tries to configure the non-configurable default-cap profile:

```
(host) ^[md] (config) #aaa authentication vpn default-cap
Predefined VPN Authentication Profile "default-cap" is not editable
```

The following example describes the steps to use the CLI to configure a VPN for Cisco Smart Card Clients using certificate authentication and IKEv1, where the client is authenticated against user entries added to the internal database:

```
(host) ^[md] (config) #aaa authentication vpn default
server-group internal
(host) ^[md] (config) #no crypto-local isakmp xauth
(host) ^[md] (config) #vpdn group l2tp
enable
client dns 101.1.1.245
(host) ^[md] (config) #ip local pool sc-clients 10.1.1.1 10.1.1.250
(host) ^[md] (config) #crypto-local isakmp server-certificate MyServerCert
(host) ^[md] (config) #crypto-local isakmp ca-certificate TrustedCA
(host) ^[md] (config) #crypto isakmp policy 1
authentication rsa-sig
```

The following command configures client entries in the internal database:

```
(host) [mynode] #local-userdb add username <name> password <password>
```

The following example configures a VPN for XAuth IKEv1 clients in config mode using a username and password:

```
(host) ^[md] (config) #aaa authentication vpn default
server-group internal
crypto-local isakmp xauth
(host) ^[md] (config) #vpdn group l2tp
enable
client dns 101.1.1.245
(host) ^[md] (config) #ip local pool pw-clients 10.1.1.1 10.1.1.250
(host) ^[md] (config) #crypto isakmp key 0987654 address 0.0.0.0 netmask 0.0.0.0
(host) ^[md] (config) #crypto isakmp policy 1
authentication pre-share
```

Enter the following command to configure client entries in the internal database:

```
(host) [mynode] #local-userdb add username <name> password <password>
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters. The default-role parameter requires PEF for VPN Users license.	Config mode on Mobility Conductor.

aaa authentication wired

```
aaa authentication wired
  blacklist-time / denylist-time <timer>
  no ...
  profile <aaa-profile>
```

Description

This command configures authentication for a client device that is directly connected to a port on the managed device. It also references an AAA profile that is configured for MAC or 802.1X authentication. The port on the managed device to which the device is connected must be configured as untrusted.

Parameter	Description
<code>blacklist-time / denylist-time <timer></code>	Sets the time to block the user. Range: 1-65535 seconds. Default: 3600 seconds.
<code>no</code>	Negates any configured parameter.
<code>profile <aaa-profile></code>	Name of the AAA profile that applies to wired authentication. This profile must be configured for a Layer-2 authentication, either 802.1X or MAC.

Example

The following commands configure an AAA profile for 802.1X authentication and a wired profile that references the AAA profile:

```
(host) ^[md] (config) aaa profile sec-wired
dot1x-default-role employee
dot1x-server-group sec-svrs
(host) ^[md] (config) aaa authentication wired
profile sec-wired
```

Related Commands

Command	Description
vlan	Assign an AAA profile to an individual VLAN to enable role-based access for wired clients connected to an untrusted VLAN or port on the managed device.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.2.0.0	The <code>blacklist-time</code> parameter was added.

aaa authentication wispr

```
aaa authentication wispr
  agent string
  clone <source>
  default-role <role>
  logon-wait {cpu-threshold <cpu-threshold>}|{maximum-delay <maximum-delay>}|{minimum-
delay <minimum-delay>}
  no ...
  max-authentication-failures
  server-group <server-group>
  wispr-location-id-ac <wispr-location-id-ac>
  wispr-location-id-cc <wispr-location-id-cc>
  wispr-location-id-isocc <wispr-location-id-isocc>
  wispr-location-id-network <wispr-location-id-network>
  wispr-location-name-location <wispr-location-name-location>
  wispr-location-name-operator-name <wispr-location-name-operator>
```

Description

This command configures WISPr authentication with the WISPr RADIUS server of an ISP.

WISPr authentication allows a smart client to remain authenticated on the network when they roam between WISPs, even if the wireless hotspot uses an ISP for which the client may not have an account.

If you are hotspot operator using WISPr authentication, and a client that has an account with your ISP attempts to access the Internet at your hotspot, then your ISP's WISPr AAA server authenticates that client directly, and allows the client access on the network. If, however, the client only has an account with a partner ISP, then your ISP's WISPr AAA server will forward that client's credentials to the partner ISP's WISPr AAA server for authentication. Once the client has been authenticated on the partner ISP, it will be authenticated on your hotspot's own ISP, as per their service agreements. Once your ISP sends an authentication message to the managed device, the managed device assigns the default WISPr user role to that client.

ArubaOS supports the following smart clients, which enable client authentication and roaming between hotspots by embedding iPass Generic Interface Specification redirect, proxy, authentication and logoff messages within HTML messages to the managed device.

- iPass
- Boingo
- Rustive
- eRoam
- T&T

A WISPr authentication profile includes parameters to define RADIUS attributes, the default role for authenticated WISPr users, maximum numbers of authenticated failures and logon wait times. The WISPr-Location-ID sent from the managed device to the WISPr RADIUS server will be the concatenation of the ISO Country Code, E.164 Country Code, E.164 Area Code and SSID or Zone parameters configured in this profile.

The parameters to define WISPr RADIUS attributes are specific to the RADIUS server your ISP uses for WISPr authentication; contact your ISP to determine these values. You can find a list of ISO and ITU country and area codes at the ISO and ITU websites www.iso.org and www.itu.int.

A Boingo smart client uses a NAS identifier in the format <CarrierID>_<VenueID> for location identification. To support Boingo clients, you must also configure the **NAS identifier** parameter in the RADIUS server profile for the WISPr server

Parameter	Description
<code>agent string</code>	User Agent String to be registered for use in WISPR Profile. Max User Agent String len: 32 characters. Max number of User Agent string: 32.
<code>clone <source></code>	Copy data from another WISPr Authentication Profile.
<code>default-role</code>	Default role assigned to users that complete WISPr authentication.
<code>logon-wait</code>	Configure the CPU utilization threshold that will trigger logon wait maximum and minimum times.
<code>CPU-threshold <cpu-threshold></code>	Percentage of CPU utilization at which the maximum and minimum login wait times are enforced. Range: 1-100%. Default: 60%.
<code>max-authentication-failures</code>	Maximum auth failures before user is blacklisted/denylister. Range: 0-10. Default: 0.
<code>maximum-delay <maximum-delay></code>	If the CPU utilization of a managed device has surpassed the CPU-threshold value, the <code>maximum-delay</code> parameter defines the minimum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 10 seconds.
<code>minimum-delay <minimum-delay></code>	If the CPU utilization of a managed device has surpassed the CPU-threshold value, the <code>minimum-delay</code> parameter defines the minimum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 5 seconds.
<code>wispr-location-id-ac <wispr-location-id-ac></code>	The E.164 Area Code in the WISPr Location ID.
<code>wispr-location-id-cc <wispr-location-id-cc></code>	The 1-3 digit E.164 Country Code in the WISPr Location ID.
<code>wispr-location-id-isocc <wispr-location-id-isocc></code>	The ISO Country Code in the WISPr Location ID.
<code>wispr-location-id-network <wispr-location-id-network></code>	The SSID or network name in the WISPr Location ID.
<code>wispr-location-name-location <wispr-location-name-location></code>	A name identifying the hotspot location. If no name is defined, the default ap-name is used.
<code>wispr-location-name-operator-name <wispr-location-name-operator></code>	A name identifying the hotspot operator.

Example

The following commands configure an WISPr authentication profile:

```
(host) ^[md] (config) aaa authentication wispr
default-role authuser
max-authentication-failures 5
server-group wisprl
```

```
wispr-location-id-ac 408
wispr-location-id-cc 1
wispr-location-id-isoccc us
wispr-location-id-network <wispr-location-id-network>
wispr-location-name-location <wispr-location-name-location>
wispr-location-name-operator-name <wispr-location-name-location>
```

aaa bandwidth-contract

```
aaa bandwidth-contract <name> {kbits <kbits>}|{mbits <mbits>}|{percentage <percentage>}
```

Description

This command configures a bandwidth contract. You can apply a configured bandwidth contract to a user role or to a VLAN. When you apply a bandwidth contract to a user role (see [user-role on page 4060](#)), you specify whether the contract applies to upstream traffic (from the client to the managed device) or downstream traffic (from the managed device to the client). You can also specify whether the contract applies to all users in a specified user role or per-user in a user role.

When you apply a bandwidth contract to a VLAN (see [interface vlan on page 776](#)), the contract limits multicast traffic and does not affect other data. This is useful because an AP can only send multicast traffic at the rate of the slowest associated client. Thus excessive multicast traffic will fill the buffers of the AP, causing frame loss and poor voice quality. Generally, every system should have a bandwidth contract of 1 Mbps or even 700 Kbps and it should be applied to all VLANs with which users are associated, especially those VLANs that pass through the upstream router. The exception are VLANs that are used for high speed multicasts, where the SSID is configured without low data rates.

Parameter	Description
<name>	Name that identifies this bandwidth contract.
kbits <kbwm>	Limit the traffic rate for this bandwidth contract to a specified number of Kbps. 256-2000000
mbits <mbwm>	Limit the traffic rate for this bandwidth contract to a specified number of Mbps. 1-2000
percentage <pbwm>	Specify bandwidth as percentage of link capacity. 1-100

Example

The following commands configure a set of bandwidth contracts, then apply those contracts to all upstream and downstream traffic except for the echo, icmp, iperf, icmp6, and synflood applications, and the web, streaming, peer-to-peer, unified-communication, and tunneling application categories.

```
(host) ^[md] (config) #aaa bandwidth-contract up-256k-1 kbits 256
(host) ^[md] (config) #aaa bandwidth-contract up-512k-1 kbits 512
(host) ^[md] (config) #aaa bandwidth-contract up-1m-1 mbits 1
(host) ^[md] (config) #aaa bandwidth-contract up-5m-1 mbits 5
(host) ^[md] (config) #aaa bandwidth-contract up-10m-1 mbits 10
(host) ^[md] (config) #aaa bandwidth-contract up-20m-1 mbits 20
(host) ^[md] (config) #aaa bandwidth-contract up-50m-1 mbits 50
(host) ^[md] (config) #aaa bandwidth-contract up-100m-1 mbits 100
(host) ^[md] (config) #aaa bandwidth-contract up-500m-1 mbits 500
(host) ^[md] (config) #aaa bandwidth-contract up-1000m-1 mbits 1000
```

```
(host) ^[md] (config) #aaa bandwidth-contract dw-256k-1 kbits 256
(host) ^[md] (config) #aaa bandwidth-contract dw-512k-1 kbits 512
(host) ^[md] (config) #aaa bandwidth-contract dw-1m-1 mbits 1
(host) ^[md] (config) #aaa bandwidth-contract dw-5m-1 mbits 5
(host) ^[md] (config) #aaa bandwidth-contract dw-10m-1 mbits 10
(host) ^[md] (config) #aaa bandwidth-contract dw-20m-1 mbits 20
(host) ^[md] (config) #aaa bandwidth-contract dw-50m-1 mbits 50
(host) ^[md] (config) #aaa bandwidth-contract dw-100m-1 mbits 100
(host) ^[md] (config) #aaa bandwidth-contract dw-500m-1 mbits 500
(host) ^[md] (config) #aaa bandwidth-contract dw-1000m-1 mbits 1000
(host) ^[md] (config) #interface gigabitethernet 0/0/1
```

Related Commands

aaa dns-query-interval

```
aaa dns-query-interval <minutes>
```

Description

Configure how often the managed device should generate a DNS request to cache the IP address for a RADIUS server identified via its FQDN.

If you define a RADIUS server using the FQDN of the server rather than its IP address, the managed device will periodically generate a DNS request and cache the IP address returned in the DNS response. Issue this command to configure the frequency of these requests.

Parameter	Description
<minutes>	Specify, in minutes, the interval between DNS requests sent from the managed device to the DNS server. 1-1440 minutes 1 minute

Example

This command configures a DNS query interval of 30 minutes.

```
(host) ^[md] (config)# aaa dns-query-interval 30
```

Related Commands

Command	Description
show aaa dns-query-interval	This command is used to view the current DNS query interval.

aaa derivation-rules

```
aaa derivation-rules user <name>
  no ...
  set {role|vlan} condition <rule-type> <attribute> <value> set-value {<role>|<vlan>}
  [description <rule description>][position <number>]
```

Description

This command configures rules which assigns a AAA profile, user role or VLAN to a client based upon the client's association with an AP.

A user role cannot be assigned by an AAA derivation rule unless the managed device has a PEFNG license.

Parameter	Description
<name>	Name that identifies this set of UDRs.
no	Negates a configured rule.
set {role vlan}	Specify whether the action of the rule is to set the role or the VLAN.
condition	Condition that should be checked to derive role or VLAN.
<rule-type>	For a rule that sets an AAA profile, use the user-vlan rule type. For a role or VLAN UDR, select one of the following rules: <ul style="list-style-type: none">■ ssid: BSSID of access point.■ dhcp-option: Use DHCP signature matching to assign a role or VLAN.■ dhcp-option-77: Enable DHCP packet processing.■ encryption-type: Encryption method used by station.■ ssid: ESSID of access point.■ location: user location (AP name).■ macaddr: MAC address of user. If you use the dhcp-option rule type, best practices are to enable the enforce-dhcp option in the AAA profile referenced by Virtual AP profile of the AP group.
<attribute><value>	Specify one of the following conditions: <ul style="list-style-type: none">■ contains: Check if attribute <i>contains</i> the string in the <value> parameter.■ ends-with: Check if attribute <i>ends with</i> the string in the <value> parameter.■ equals: Check if attribute <i>equals</i> the string in the <value> parameter.■ not-equals: Check if attribute <i>is not equal</i> to the string in the <value> parameter.■ starts-with: Check if attribute <i>starts with</i> the string in the <value> parameter.
set-value <role> <vlan>	Specify the user role or VLAN ID to be assigned to the client if the above condition is met.

Parameter	Description
description	Describes the UDR. This parameter is optional and has a 128 character maximum.
position	Position of this rule relative to other rules that are configured.

The user role can be derived from attributes from the client's association with an AP. UDRs are executed before the client is authenticated.

You configure the user role to be derived by specifying condition rules; when a condition is met, the specified user role is assigned to the client. You can specify more than one condition rule; the order of rules is important as the first matching condition is applied. You can also add a description of the rule.

The table below describes the conditions for which you can specify a user role or VLAN.

Rule Type	Condition	Value
bssid: Assign client to a role or VLAN based upon the BSSID of AP to which client is associating.	One of the following: <ul style="list-style-type: none"> contains ends with equals does not equal starts with 	MAC address (xx:xx:xx:xx:xx:xx)
dhcp-option: Assign client to a role or VLAN based upon the DHCP signature ID.	One of the following: <ul style="list-style-type: none"> equals starts with 	DHCP signature ID. This string is <i>not</i> case sensitive.
dhcp-option-77: Assign client to a role or VLAN based upon the user class identifier returned by DHCP server.	equals	string
encryption-type: Assign client to a role or VLAN based upon the encryption type used by the client.	One of the following: <ul style="list-style-type: none"> equals does not equal 	<ul style="list-style-type: none"> Open (no encryption) WPA or WPA2 AES WPA-TKIP (static or dynamic) Dynamic WEP WPA or WPA2 AES PSK Static WEP xSec
essid: Assign client to a role or VLAN based upon the ESSID to which the client is associated.	One of the following: <ul style="list-style-type: none"> contains ends with equals does not equal starts with value of (does not take <i>string</i>; attribute value is used as role) 	string

Rule Type	Condition	Value
location: Assign client to a role or VLAN based upon the AP name to which the client is associated.	One of the following: <ul style="list-style-type: none"> ■ equals ■ does not equal 	string
macaddr: MAC address of the client.	One of the following: <ul style="list-style-type: none"> ■ contains ■ ends with ■ equals ■ does not equal ■ starts with 	MAC address (xx:xx:xx:xx:xx:xx)

The device identification feature allows you to assign a user role or VLAN to a specific device type by identifying a DHCP option and signature for that device. If you create a user rule with the **DHCP-Option** rule type, the first two characters in the **Value** field must represent the hexadecimal value of the DHCP option that this rule should match, while the rest of the characters in the **Value** field indicate the DHCP signature the rule should match. To create a rule that matches DHCP option 12 (host name), the first two characters of the in the **Value** field must be the hexadecimal value of 12, which is 0C. To create a rule that matches DHCP option 55, the first two characters in the **Value** field must be the hexadecimal value of 55, which is 37.

The following table describes some of the DHCP options that are useful for assigning a user role or VLAN.

DHCP Option	Description	Hexadecimal Equivalent
12	Host name	0C
55	Parameter Request List	37
60	Vendor Class Identifier	3C
81	Client FQDN	51

To identify DHCP strings used by an individual device, access the CLI in config mode and issue the following command to include DHCP option values for DHCP-DISCOVER and DHCP-REQUEST frames in the log file of the managed device:

```
logging level debugging network process dhcpd
```

Now, connect the device you want to identify to the network, and issue the CLI command `show log network`. The sample below is an example of the output that may be generated by this command.

Be aware that each device type may not have a unique DHCP fingerprint signature. For example, devices from different manufacturers may use vendor class identifiers that begin with similar strings. If you create a DHCP-Option rule that uses the starts-with condition instead of the equals condition, the rule may assign a role or VLAN to more than one device type.

```

Examples

The following command sets the client's user role to "guest" if the client associates to the "Guest" ESSID. The rule description indicates that it was created for special customers.

```
(host) ^[md] (config) aaa derivation-rules user derive1
set role condition essid equals Guest set-value guest description
createdforspecialcustomers
```

The example rule shown below sets a user role for clients whose host name (DHCP option 12) has a value of 6C6170746F70, which is the hexadecimal equivalent of the ASCII string "laptop". The first two digits in the Value field are the hexadecimal value of 12 (which is 0C), followed by the specific signature to be matched.

```
(host) ^[md] (config) aaa derivation-rules user device-role
set role condition dhcp-option equals 0C6C6170746F70 set-value laptop_role
```

Command Information

Platform	License	Command Mode
All platforms	Base operating system. The PEFNG license must be installed for a user role to be assigned.	Config mode on Mobility Conductor.

aaa inservice

```
aaa inservice <server-group> <server>
```

Description

This command designates an out of service authentication server to be in service.

By default, Mobility Conductor marks an unresponsive authentication server as “out of service” for a period of 10 minutes (you can set a different time limit with the `aaa timers dead-time` command). The `aaa inservice` command is useful when you become aware that an “out of service” authentication server is again available before the dead-time period has elapsed. You can use the `aaa test-server` command to test the availability and response of a configured authentication server.

Parameter	Description
<server-group>	Server group to which this server is assigned.
<server>	Name of the configured authentication server.

Example

The following command sets an authentication server to be in service:

```
aaa inservice corp-rad rad1
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

aaa ipv6 user add

```
aaa ipv6 user add <ipv6addr>
  authentication-method {dot1x|stateful-dot1x}
  mac <macaddr>
  name <username>
  profile <aaa-profile>
  role <role>
```

Description

This command should only be used for troubleshooting issues with a specific IPv6 client. This command manually assigns a user role or other values to a specified IPv6 client. For example, you can create a role debugging that includes a policy to mirror session packets to a specified destination for further examination, then use this command to assign the debugging role to a specific client. Use the `aaa ipv6 user delete` command to remove the client or device from the role.

Issuing this command does not affect ongoing sessions that the client may already have. For example, if a client is in the “employee” role when you assign them to the “debugging” role, the client continues any sessions allowed with the “employee” role. Use the `aaa ipv6 user clear-sessions` command to clear ongoing sessions.

Parameter	Description
<ipv6addr>	IPv6 address of the user to be added.
authentication-method	Authentication method for the client.
dot1x	802.1X authentication.
stateful-dot1x	Stateful 802.1X authentication.
mac <macaddr>	MAC address of the client.
name <username>	Name of the client.
profile <aaa-profile>	AAA profile for the client.
role <role>	User role for the client.

Example

The following commands create a role that logs HTTPS traffic, then assign the role to a specific IPv6 client:

```
(host) [\md] (config) #ip access-list session ipv6-log-https
(host) [\md] (config-submode) #any any svc-https permit log
(host) [\md] (config) #user-role ipv6-web-debug
(host) [\md] (config-submode) #session-acl ipv6-log-https
(host) [\md] (config) #aaa ipv6 user add 2002:d81f:f9f0:1000:e409:9331:1d27:ef44 role
ipv6-web-debug
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

aaa ipv6 user clear-sessions

```
aaa ipv6 user clear-sessions <ipaddr>
```

Description

This command clears any ongoing sessions that the client already had before being assigned a role with the `aaa ipv6 user add` command.

Parameter	Description
<ipv6addr>	IPv6 address of the client.

Example

The following command clears ongoing sessions for an IPv6 client:

```
(host) [/md] (config) #aaa user clear-sessions  
2002:d81f:f9f0:1000:e409:9331:1d27:ef44
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

aaa ipv6 user delete

```
aaa ipv6 user delete {<ipv6addr>|all|mac <macaddr>|name <username>|role <role>}
```

Description

This command allows you to manually delete clients, users, or roles. For example, if you used the `aaa ipv6 user add` command to assign a user role to an IPv6 client, you can use this command to remove the role assignment.

Parameter	Description
<ipv6addr>	IPv6 address of the client to be deleted.
all	Deletes all connected IPv6 clients.
mac <macaddr>	MAC address of the IPv6 client to be deleted.
name <username>	Name of the IPv6 client to be deleted.
role <role>	Role of the IPv6 client to be deleted.

Example

The following command a role:

```
(host) [/md] (config) #aaa ipv6 user delete role web-debug
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

aaa ipv6 user logout

```
aaa ipv6 user logout <ipv6addr>
```

Description

This command logs out an authenticated IPv6 client. The client must reauthenticate.

Parameter	Description
<ipv6addr>	IPv6 address of the client to be logged out.

Example

The following command logs out an IPv6 client:

```
(host) [/md] (config) #aaa user logout 2002:d81f:f9f0:1000:e409:9331:1d27:ef44
```

Command History

Release	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

aaa log

[no] aaa log

Description

Enable per-user log files for AAA events.

By default, logging is always enabled. Issue the `no aaa log` command to disable per-user logging and re-enable it again using the command `aaa log`.

Example

The example below enables per-user AAA log files.

```
(host) ^[md] (config) #aaa log
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

aaa profile

```
aaa profile <profile>
  ageout-bridge-user
  authentication-dot1x <dot1x-profile>
  authentication-mac <mac-profile>
  clone <profile>
  devtype-classification
  dh-groups
  dot1x-default-role <role>
  dot1x-server-group <group>
  download-role
  enforce-dhcp
  initial-role <role>
  l2-auth-fail-through
  mac-default-role <role>
  mac-server-group <group>
  max-ip ipv4 wireless <max_ipv4_users>
  multiple-server-accounting
  no ...
  open ssid radius accounting
  pan-integration
  radius-accounting <group>
  radius-acct-session-id-in-access
  radius-interim-accounting
  radius-roam-accounting
  reauth-wired-user-vlan-change
  rfc-3576-server <ipaddr>
  user-derivation-rules <profile>
  user-idle-timeout
  username-from-dhcp-opt12
  wired-to-wireless-roam
  xml-api-server <ipaddr>
```

Description

This command configures the authentication for a WLAN.

Parameter	Description
<profile>	Name that identifies this instance of the profile. The name must be 1-63 characters. default
ageout-bridge-user	Enables ageout mechanism for wireless clients in bridge mode.
authentication-dot1x <dot1x-profile>	Name of the 802.1X authentication profile associated with the WLAN.
authentication-mac <mac-profile>	Name of the MAC authentication profile associated with the WLAN.
clone <profile>	Name of an existing AAA profile configuration from which parameter values are copied.

Parameter	Description
<code>devtype-classification</code>	The device identification feature can automatically identify different client device types and operating systems by parsing the User-Agent strings in a client's HTTP packets. When the <code>devtype-classification</code> parameter is enabled, the output of the <code>show user</code> and <code>show user-table</code> commands shows each client's device type, if that client device can be identified. enabled
<code>dh-groups</code>	Set supported D-H groups for EnhancedOpen
<code>dot1x-default-role <role></code>	Configured role assigned to the client after 802.1X authentication. If derivation rules are present, the role assigned to the client through these rules take precedence over the default role. This parameter requires the PEFNG license. guest
<code>dot1x-server-group <group></code>	Name of the server group used for 802.1X authentication.
<code>download-role</code>	Enables role download from ClearPass Policy Manager if not defined. 2
<code>enforce-dhcp</code>	When you enable this option, clients must complete a DHCP exchange to obtain an IP address. disabled
<code>initial-role <role></code>	Role for unauthenticated users. logon
<code>l2-auth-fail-through</code>	To select different authentication method if one fails. disabled
<code>mac-default-role <role></code>	Configured role assigned to the user when the device is MAC authenticated. If derivation rules are present, the role assigned to the client through these rules take precedence over the default role. This parameter requires the PEFNG license. guest
<code>mac-server-group group</code>	Name of the server group used for MAC authentication.
<code>max-ip ipv4 wireless <max_ipv4_users></code>	Control the number of IPv4 addresses that can be associated to single wireless user. Increasing the max-ip limit may prevent the system from scaling to maximum users on all Mobility Conductor or managed devices. Range: 1-32 2
<code>multiple-server-accounting</code>	If enabled, the Mobility Conductor sends RADIUS accounting to all servers in RADIUS accounting server group. disabled

Parameter	Description
no	Negates any configured parameter.
open ssid radius accounting	Initiates RADIUS accounting as soon as the user associates to an Open SSID without any authentication. Do not enable this parameter for wired users. If enabled, the Mobility Conductor sends RADIUS accounting packets for unauthenticated wired users. disabled
pan-integration	The profile requires mapping at a Palo Alto Networks (PAN) firewall. disabled
radius-accounting <group>	Name of the server group used for RADIUS accounting.
radius-acct-session-id-in-access	Use this to include Acct-Session-Id in RADIUS Access-Request.
radius-interim-accounting	By default, the RADIUS accounting feature sends only start and stop messages to the RADIUS accounting server. Issue the interim-radius-accounting command to allow the managed device to send Interim-Update messages with current user statistics to the server at regular intervals. disabled
rfc-3576-server <ip-addr>	IPv4 or IPv6 address of a RADIUS server that can send user disconnect, session timeout and CoA messages, as described in RFC 3576, Dynamic Authorization Extensions to RADIUS. This parameter requires the PEFNG license.
radius-roam-accounting	Enable the managed device to send Interim-Update messages (without user statistics) to the server, when a client roams to a different AP.
reauth-wired-user-vlan-change	When a wired user moves across VLANs, a trigger is created to reauthenticate this user. Enabled
user-derivation-rules <profile>	User attribute profile from which the user role or VLAN is derived.
user-idle-timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. A value of 0, deletes the user immediately after disassociation from the wireless network. Valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used. disabled
username-from-dhcp-opt12	Enter a username from dhcp option 12 for non-802.1X users.
wired-to-wireless-roam	Keeps user authenticated when roaming from the wired side of the network. enabled

Parameter	Description
<code>xml-api-server <ip-addr></code>	IP address of a configured XML API server. This parameter requires the PEFNG license.

The AAA profile defines the user role for unauthenticated users, the default user role for MAC or 802.1X authentication, and UDRs. The AAA profile contains the authentication profile and authentication server group.

There are predefined AAA profiles available, `default-dot1x`, `default-mac-auth`, and `default-open`. These profiles have the parameter values shown in the following table.

Parameter	<code>default-dot1x</code>	<code>default-mac-auth</code>	<code>default-open</code>
<code>authentication-dot1x</code>	default	N/A	N/A
<code>authentication-mac</code>	N/A	default	N/A
<code>dot1x-default-role</code>	authenticated	guest	guest
<code>dot1x-server-group</code>	N/A	N/A	N/A
<code>initial-role</code>	logon	logon	logon
<code>mac-default-role</code>	guest	authenticated	guest
<code>mac-server-group</code>	default	default	default
<code>radius-accounting</code>	N/A	N/A	N/A
<code>rfc-3576-server</code>	N/A	N/A	N/A
<code>user-derivation-rules</code>	N/A	N/A	N/A
<code>wired-to-wireless roam</code>	enabled	enabled	enabled

Changing the `max-ip ipv4 wireless` parameter from the default value is recommended for special deployments. If your WLAN has multiple device IP associated to single MAC address, you can increase the this value from the default value of 2.

The default value is 2 IPv4 users per wireless user. Total number of IPv4 users created can be a maximum of two times the license. If you configure 32 `max-ip IPv4 users` , total number of IPv4 users is 32 times the license. This can prevent the managed device from scaling to the maximum limit of IP users. Total number of IPv4 users should be scaled down to offset this issue.

Increasing the value of the `max-ip ipv4 wireless` parameter may increase the look-up time due to an increase in the creation and deletion of IPv4 users on the managed device. In a deployment where there is Captive Portal and 802.1X authentication implemented, increasing the number of IPv4 users can further deplete performance.

Example

The following command configures an AAA profile that assigns the employee role to clients after they are authenticated using the 802.1X server group `radiusnet`.

```
(host) ^[md] (config) #aaa profile corpnet
(host) ^[md] (AAA Profile "corpnet")dot1x-default-role employee
(host) ^[md] (AAA Profile "corpnet")dot1x-server-group radiusnet
```

Command History

Release	Modification
ArubaOS 8.7.0.0	The <code>ageout-bridge-user</code> parameter was introduced.
ArubaOS 8.5.0.0	The <code>rfc-3576-server <ipaddr></code> parameter was updated to also support IPv6 address of the server.
ArubaOS 8.3.0.0	The <code>reauth-wired-user-vlan-change</code> parameter was added.
ArubaOS 8.1.0.0	The <code>radius-roam-accounting</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

aaa password-policy mgmt

```
aaa password-policy mgmt
  certificate-lock-out
  certificate-lock-out-time
  enable
  min-char-difference
  no
  password-lock-out
  password-lock-out-time
  password-max-character-repeat.
  password-min-digit
  password-min-length
  password-min-lowercase-characters
  password-min-special-character
  password-min-uppercase-characters
  password-not-username
```

Description

Defines a policy for creating management user passwords. By default, the password for a management user has no requirements other than a minimum length of 6 alphanumeric or special characters. You do not need to configure a different management user password policy unless your company enforces a best practices password policy for management users with root access to network equipment.

Parameter	Description
certificate-lock-out	Configure the number of failed attempts within 3 minute window to lockout the user. Provides ability to reduce the number of login attempts that can be made in a short time. Automatically clears the lockout at the end of configured lock-out period. Range: 0-10 attempts. Default: 0 (By default, the user lockout feature is disabled)
certificate-lock-out-time	Configure the number of minutes for which the user is locked out. The lockout is cleared without administrator intervention. Range: 1 min to 1440 min (24 hrs). Default: 3 min.
enable	Enable the password management policy.
password-lock-out	The number of failed attempts within a 3 minute window that causes the user to be locked out for the period of time specified by the password-lock-out-time parameter. Range: 0-10 attempts. By default, the password lockout feature is disabled, and the default value of this parameter is 0 attempts.
password-lock-out-time	The number of minutes a user who has exceeded the maximum number of failed password attempts is locked out of the network. After this period has passed, the lockout is cleared without administrator intervention.

Parameter	Description
	<p>When a management user gets locked out, that event is logged in the managed device log file. The management user lockout warning message can have any one of the following warning IDs.</p> <ul style="list-style-type: none"> ■ 125060 = Password policy locked out a management user created via the <code>mgmt-user</code> command in the serial console CLI. ■ 125061 = Password policy locked out a management user created via the WebUI or the <code>mgmt-user</code> command in the Telnet or SSH CLI. ■ 133109 = Password policy locked out a management user created via the <code>local-userdb</code> command in the CLI. <p>Range: 1-1440 3</p>
<code>password-max-character-repeat</code>	<p>The maximum number of consecutive repeating characters allowed in a management user password.</p> <p>Range: 0-10 characters. By default, there is no limitation on the numbers of character that can repeat within a password, and the parameter has a default value of 0 characters.</p>
<code>password-min-digit</code>	<p>The minimum number of numeric digits required in a management user password.</p> <p>Range: 0-10 digits. By default, there is no requirement for numerical digits in a password, and the parameter has a default value of 0.</p>
<code>password-min-length</code>	<p>The minimum number of characters required for a management user password</p> <p>Range: 6-64 characters. Default: 6.</p> <p>Starting from ArubaOS 8.10.0.0, the range of characters in the management user password is increased from 6-64 to 6-128.</p>
<code>password-min-lowercase-characters</code>	<p>The minimum number of lowercase characters required in a management user password.</p> <p>Range: 0-10 characters. By default, there is no requirement for lowercase letters in a password, and the parameter has a default value of 0.</p>
<code>password-min-special-characters</code>	<p>The minimum number of special characters (!, @, #, \$, %, ^, &, *, <, >, {, }, [,], :, ., comma, , +, ~, `) in password. Range: 0-10 special characters.</p> <p>Default: 0 (minimum number of special character required is disabled by default, The following ('), ' (; , - , space, =, /, ?) are dis-allowed).</p>
<code>password-min-special-character</code>	<p>The minimum number of special characters required in a management user password.</p> <p>Range: 0-10 characters. By default, there is no requirement for special characters in a password, and the parameter has a default value of 0. See Usage Guidelines below for a list of allowed and disallowed special characters</p>
<code>password-min-uppercase-characters</code>	<p>The minimum number of uppercase characters required in a management user password.</p>

Parameter	Description
	Range: 0-10 characters. By default, there is no requirement for uppercase letters in a password, and the parameter has a default value of 0.
password-not-username	Password cannot be the current username or the username spelled backwards of the management user.

Example

The following command sets a management password policy that requires the password to have a minimum of nine characters, including one numerical digit and one special character:

```
(host) ^[md] (config) aaa password-policy mgmt
enable
password-min-digit 1
password-min-length 9
password-min-special-characters 1
```

Related Commands

Command	Description
show aaa password-policy mgmt	This command displays the current management password policy.

Command History

Release	Modification
ArubaOS 8.10.0.0	The range of characters in the management user password is increased from 6-64 to 6-128.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa query-user

```
aaa query-user <auth-server> <user-name> <mac-address>
```

Description

Troubleshoot an authentication failure by verifying that the user exists in the authentication server database. If the Admin-DN binds successfully but the wireless user fails to authenticate, issue this command to troubleshoot whether the problem is with the wireless network, the managed device, or the authentication server. The `aaa query-user <auth_server> <username> <mac-address>` command to make the managed device sends a search query to find the user. If that search fails in spite of the user being in the server database, it is most probable that the base DN where the search was started was not correct. In such case, it is advisable to make the base DN at the root of the authentication server tree.

Parameter	Description
<auth-server>	Name of a configured authentication server.
<user-name>	Name of a user whose authentication record you want to view.
<mac-address>	MAC address of the client.

Example

The example below shows part of the output for an LDAP record for the username JDOE.

```
(host) [mynode] #aaa query-user eng JDOE
(host) [mynode] #objectClass: top
(host) [mynode] #objectClass: person
(host) [mynode] #objectClass: organizationalPerson

aaa radius-attributes

```
aaa radius-attributes add <attribute> <attribute-id> {date|integer|ipaddr|string} [vendor <name> <vendor-id>]
```

Description

This command configures RADIUS attributes to statically configure values to be included in RADIUS Access-Requests and Accounting-Requests. Add RADIUS attributes for use in SDRs. Use the `show aaa radius-attributes` command to display a list of the current RADIUS attributes recognized by the Mobility Conductor. To add a RADIUS attribute to the list, use the `aaa radius-attributes` command.

Parameter	Description
<code>add <attribute> <attribute-id></code>	Adds the specified attribute name (alphanumeric string), associated attribute ID (integer), and type (date, integer, IP address, or string).
<code>date</code>	Adds a date attribute.
<code>integer</code>	Adds an <code>integer</code> attribute.
<code>ipaddr</code>	Adds an IP address attribute.
<code>string</code>	Adds a string attribute.
<code>vendor</code>	(Optional) Display attributes for a specific vendor name and vendor ID.

Example

The following command adds the VSA Aruba-User-Role:

```
(host) ^[md] (config) aaa radius-attributes add Aruba-User-Role 1 string vendor Arubas 14823
```

Command History

Release	Modification

aaa radius modifier

```
aaa radius modifier <rad_modifier_name>
  clone <source>
  exclude <name>
  include <name> {[static <static_val>]}[dynamic <ap-group1>|<ap-macaddr1>|<ap-
name1>|<ssid1>|<user-vlan1>|<with>|<ap-group2>|<ap-macaddr2>|<ap-
name2>|<ssid2>|<user-vlan2>]<delimiter>}
no..
```

Description

This command configures the RADIUS modifier profile to customize the attributes that are included, excluded and modified in the RADIUS request before it is sent to the authentication server.

Use the `show aaa radius modifier` command to display a list of RADIUS modifier profiles. To create a RADIUS modifier profile with customized attributes, use the `aaa radius-attributes` command.

Parameter	Description
<rad_modifier_name>	The specified RADIUS modifier profile name
clone <source>	Copy data from another Radius Modifier Profile
exclude <name>	Attribute to be excluded in RADIUS request
include <name>	Attribute/Value to be included in RADIUS request
static <static_val>	Static data. (1-128 bytes string in length)
dynamic	First dynamic field. Use the following parameters: <ul style="list-style-type: none">▪ ap-group1: Use AP group as the first dynamic field.▪ ap-macaddr1: Use AP mac address as the first dynamic field.▪ ap-name1: Use AP name as the first dynamic field.▪ ssid1: Use ssid as the first dynamic field.▪ user-vlan1: Use the current VLAN-ID of user as the first dynamic field.
with	(Optional) Connect to the second dynamic field. Use the following parameters: <ul style="list-style-type: none">▪ ap-group2: Use AP group as the second dynamic field.▪ ap-macaddr2: Use AP mac address as the second dynamic field.▪ ap-name2: Use AP name as the second dynamic field.▪ ssid2: Use ssid as the second dynamic field.▪ user-vlan2: Use the current VLAN-ID of user as the second dynamic field.
delimiter	Delimiter (at, colon, dash, dollar, hash, none, percent, semicolon, slash, space) used in the string.
no	Delete Command.

Example

Example for Included attribute

```
(host) [md](config) #aaa radius-attributes add BW-Area-Code 18 integer vendor
Boingo 22472
(host) [md](Radius Modifier Profile "radmodifier1") # include BW-Area-Code static
"212"
(host) [md](Radius Modifier Profile "radmodifier1") # no include BW-Area-Code
```

Example for excluded attribute

```
(host) [md](config) #aaa radius-attributes add BW-Area-Code 18 integer vendor
Boingo 22472
(host) [md](Radius Modifier Profile "radmodifier1") # exclude BW-Area-Code
(host) [md](Radius Modifier Profile "radmodifier1") # no exclude BW-Area-Code
```

Example for modified attribute

Default attributes to carry to radius server can be modified with include option.

```
(host) [md](Radius Modifier Profile "radmodifier1") # include "Aruba-location-id"
static "Shim-office"
```

Command History

Version	Modification
ArubaOS 8.2.0.0	The exclude and include parameters were added.
ArubaOS 8.1.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa rfc-3576-server

```
aaa rfc-3576-server <ipaddr>
  clone <source>
  enable-radsec
  event-timestamp-requi..
  key <psk>
  no ...
  replay-protection
  window-duration
```

Description

This command configures a RADIUS server that can send user disconnect, session timeout, and CoA messages, as described in RFC 3576, Dynamic Authorization Extensions to RADIUS.

The disconnect, session timeout and change-of-authorization messages sent from the server to managed device contains information to identify the user for which the message is sent. Starting from ArubaOS 8.5.0.0, the managed device also accepts disconnect, session timeout, and CoA message requests from IPv6 address based DAC, and identifies user sessions based on the user's IPv6 address. Managed Device supports the following attributes for identifying the users who authenticate with an RFC 3576 server:

- **user-name:** name of the user to be authenticated
- **framed-ip-address:** user IPv4 address
- **framed-ipv6-address:** user IPv6 address
- **calling-station-id:** phone number of a station that originated a call
- **accounting-session-id:** unique accounting ID for the user session.

If the authentication server sends both supported and unsupported attributes to managed device, the unknown or unsupported attributes will be ignored. If no matching user is found managed device will send a 503: Session Not Found error message back to the RFC 3576 server.

Parameter	Description
<ipaddr>	IPv4 or IPv6 address of the server.
clone <source>	Name of an existing RFC 3576 server configuration from which parameter values are copied.
enable-radsec	Enable RADSEC for the server.
event-timestamp-required	To enable discard of DAC request, if Event-Timestamp is not present in DAC request. This option will only come into the effect, if replay-protection is enabled.
key <psk>	Shared secret to authenticate communication between the RADIUS client and server.
no	Negates any configured parameter.
replay-protection	Enable replay protection for DAC requests.
window-duration	Number in seconds. Default value is 300. This parameter is used:

Parameter	Description
	<ul style="list-style-type: none"> - To check stale DAC requests. - To specify the minimum time-span in seconds between two valid requests with same identifiers, to check replay protection and identify duplicates.

Example

The following command configures an RFC 3576 server:

```
(host) ^[md] (config) aaa rfc-3576-server 10.1.1.245
clone default
key P@$$w0rD;
```

Related Commands

Command	Description
show aaa state user	View information for a user whose session timeout is altered by a RFC 3576 server.

Command History

Release	Modification
ArubaOS 8.5.0.0	The <ipaddr> sub-parameter was updated to also support IPv6 address of the server.
ArubaOS 8.2.0.0	Event-timestamp-required, replay-protection, and window-duration parameters were added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

aaa server-group

```
aaa server-group <group>
  allow-fail-through
  auth-server <name> [match-authstring contains|equals|starts-with <string>] [match-fqdn
<string>] [position <number>] [trim-fqdn]
  clone <source>
  load-balance
  no ...
  set role|vlan condition <attribute> contains|ends-with|equals|not-equals|starts-with
<string> set-value <set-value-str> [position <number>]
```

Description

This command allows you to add a configured authentication server to an ordered list in a server group, and configure server rules to derive a user role, VLAN ID or VLAN name from attributes returned by the server during authentication.

You create a server group for a specific type of authentication or for accounting. The list of servers in a server group is an ordered list, which means that the first server in the group is always used unless it is unavailable (in which case, the next server in the list is used). You can configure servers of different types in a server group, for example, you can include the internal database as a backup to a RADIUS server. You can add the same server to multiple server groups. There is a predefined server group internal that contains the internal database.

Parameter	Description
<group>	Name that identifies the server group. The name must be 32 characters or less.
allow-fail-through	When this option is configured, an authentication failure with the first server in the group causes the Mobility Conductor to attempt authentication with the next server in the list. The Mobility Conductor attempts authentication with each server in the ordered list until either there is a successful authentication or the list of servers in the group is exhausted.
auth-server <name>	Name of a configured authentication server.
match-authstring	This option associates the authentication server with a match rule that the Mobility Conductor can compare with the user or client information in the authentication request. With this option, the user or client information in the authentication request can be in any of the following formats: <domain>\<user> <user>@<domain> host/<pc-name>.<domain> An authentication request is sent to the server only if there is a match between the specified match rule and the user or client information. You can configure multiple match rules for an authentication server.
contains	The rule matches if the user or client information contains the specified string.

Parameter	Description
<code>equals</code>	The rule matches if the user or client information exactly matches the specified string.
<code>starts-with</code>	The rule matches if the user or client information starts with the specified string.
<code>match-fqdn <string></code>	This option associates the authentication server with a specified domain. An authentication request is sent to the server only if there is an exact match between the specified domain and the <domain> portion of the user information sent in the authentication request. With this option, the user information must be in one of the following formats: <domain>\<user> <user>@<domain>
<code>position <number></code>	Position of the server in the server list. 1 is the top.
<code>trim-fqdn</code>	This option causes the user information in an authentication request to be edited before the request is sent to the server. Specifically, this option: removes the <domain>\ portion for user information in the <domain>\<user> format removes the @<domain> portion for user information in the <user>@<domain> format.
<code>clone <source></code>	Name of an existing server group from which parameter values are copied.
<code>load-balance</code>	Enables load-balancing of authentication requests among different servers in a server group.
<code>no</code>	Negates any configured parameter.
<code>set role vlan</code>	Assigns the client a user role, VLAN ID or VLAN name based on attributes returned for the client by the authentication server. Rules are ordered: the first rule that matches the configured condition is applied. VLAN IDs and VLAN names cannot be listed together.
<code>condition</code>	Attribute returned by the authentication server.
<code>contains</code>	The rule is applied if and only if the attribute value contains the specified string.
<code>ends-with</code>	The rule is applied if and only if the attribute value ends with the specified string.
<code>equals</code>	The rule is applied if and only if the attribute value equals the specified string.
<code>not-equals</code>	The rule is applied if and only if the attribute value is not equal to the specified string.
<code>starts-with</code>	The rule is applied if and only if the attribute value begins with the specified string.
<code>set-value</code>	User role or VLAN applied to the client when the rule is matched.

Parameter	Description
value-of	Sets the user role or VLAN to the value of the attribute returned. The user role or VLAN ID returned as the value of the attribute must already be configured on the Mobility Conductor when the rule is applied.

Example

The following command configures a server group corp-servers with a RADIUS server as the main authentication server and the internal database as the backup. The command also sets the client's user role to the value of the returned Class attribute.

```
(host) ^[md] (config) aaa server-group corp-servers
auth-server radius1 position 1
auth-server internal position 2
set role condition Class value-of
load-balance
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

aaa tacacs-accounting

```
aaa tacacs-accounting
  command {action|all|configuration|show}
  no
  server-group <sg>
```

Description

This command configures reporting of commands issued from a managed device to a TACACS+ server group.

Parameter	Description
command	The types of commands that are reported to the TACACS server group.
action	Reports action commands only.
all	Reports all commands.
configuration	Reports configuration commands only.
show	Reports show commands only.
no	Delete command.
server-group <sg>	The TACACS server group to which the reporting is sent.

Example

The following command enables accounting and reporting of configuration commands to the server-group "tacacs1":

```
(host) [mm] (config) #aaa tacacs-accounting
(host) ^[mm] (config-submode) #server-group tacacs1
(host) ^[mm] (config-submode) #command configuration
```

Command History

aaa test-server

```
aaa test-server {mschapv2|pap} <server-name> <username> <passwd> {<STRING>} {<verbose>}
```

Description

This command allows you to check a configured RADIUS authentication server or the internal database. You can use this command to check for an out of service RADIUS server.

Parameter	Description
mschapv2	Use MSCHAPv2 authentication protocol.
pap	Use PAP authentication protocol.
<server-name>	Name of the configured authentication server.
<username>	Username to use to test the authentication server.
<passwd>	Password to use to test the authentication server.
<STRING>	MAC address of the user.
<verbose>	RADIUS server response for a successful or failed authentication.

Example

The following commands add a user in the internal database and verify the configuration:

```
(host) [mynode] #local-userdb add username raduser1 password raduser  
(host) [mynode] #aaa test-server mschapv2 internal raduser1 raduser verbose
```

Starting from ArubaOS 8.1.0, the `aaa test-server` command has a new `verbose` option that displays the RADIUS server's response on a successful or failed authentication.

The following command displays the RADIUS server attributes as returned by the server.

```
(host) [mynode] #aaa test-server mschapv2 internal raduser1 raduser verbose  
Authentication Successful  
Processing time (ms) : 1.397  
Attribute value pairs in response  
-----  
Vendor  Attribute  Value  
-----  -  
MS-CHAPv2  
Role      guest
```

Command History

Release	Modification
ArubaOS 8.1.0.0	The verbose parameter was added.
ArubaOS 8.0.0.0	Command introduced.

aaa timers

```
aaa timers
  dead-time <minutes>
  idle-timeout <time> [seconds]
  logon-lifetime <0-255>
  stats-timeout <time> [seconds]
```

Description

This command configures the timers that you can apply to clients and servers.

Parameter	Description
dead-time <minutes>	<p>Maximum period, in minutes, that the Mobility Conductor considers an unresponsive authentication server to be out of service.</p> <p>This timer is only applicable if there are two or more authentication servers configured on the Mobility Conductor. If there is only one authentication server configured, the server is never considered out of service and all requests are sent to the server.</p> <p>If one or more backup servers are configured and a server is unresponsive, it is marked as out of service for the dead time; subsequent requests are sent to the next server on the priority list for the duration of the dead time. If the server is responsive after the dead time has elapsed, it can take over servicing requests from a lower-priority server; if the server continues to be unresponsive, it is marked as down for the dead time.</p> <p>0-60 10</p>
idle-timeout <1-15300>	<p>Maximum number of minutes after which a client is considered idle if there is no user traffic from the client.</p> <p>The timeout period is reset if there is a user traffic. If there is no IP traffic in the timeout period or there is no 802.11 traffic as indicated in the station ageout time that is set in the wlan ssid profile, the client is aged out. Once the timeout period has expired, the user is removed immediately and no ping request is sent. If the seconds parameter is not specified, the value defaults to minutes.</p> <p>1-255 5</p>
logon-lifetime	<p>Maximum time, in minutes, that unauthenticated clients are allowed to remain logged on.</p> <p>0-255 5</p>
stats-timeout	<p>User Interim stats timeout value. If the seconds parameter is not specified, the value defaults to minutes. Starting from ArubaOS 8.7.1.3, the range of this parameter has been modified to 1-60.</p> <p>5-60 10</p>

Example

The following command changes the idle time to 10 minutes:

```
(host) ^[md] (config) aaa timers idle-timeout 10
```

Related Commands

Command	Description
show aaa timers	Displays AAA timer values.
show datapath	Displays datapath user statistics such as current entries, pending deletes, high water mark, maximum entries, total entries, allocation failures, invalid users and maximum link length.

Command History

Release	Modification
ArubaOS 8.2.0.0	The range of stats-timeout parameter was added.
ArubaOS 8.0.0.0	Command introduced.

aaa trusted-ap

aaa trusted-ap <macaddr>

Description

This command configures a trusted non-Aruba AP.

Parameter	Description
<macaddr>	MAC address of the AP.

Example

The following command configures a trusted non-Aruba AP:

```
aaa trusted-ap 00:40:96:4d:07:6e
```

Command History

aaa user add

```
aaa user add <ipaddr> [<nusers>] [authentication-method {dot1x|mac|stateful-dot1x|vpn|web}] [mac-addr <macaddr>] [name <username>] [profile <aaa_profile>] [role <role>]
```

Description

This command manually assigns a user role or other values to a specified client or device.

This command should only be used for troubleshooting issues with a specific client or device. This command allows you to manually assign a client or device to a role. For example, you can create a role debugging that includes a policy to mirror session packets to a specified destination for further examination, then use this command to assign the debugging role to a specific client. Use the `aaa user delete` command to remove the client or device from the role.

Note that issuing this command does not affect ongoing sessions that the client may already have. For example, if a client is in the employee role when you assign them to the debugging role, the client continues any sessions allowed with the employee role. Use the `aaa user clear-sessions` command to clear ongoing sessions.

Parameter	Description
<ipaddr>	IP address of the user to be added.
<nusers>	Number of users to create starting with <ipaddr>.
authentication-method	Authentication method for the user.
dot1x	802.1X authentication.
mac-addr	MAC authentication.
stateful-dot1x	Stateful 802.1X authentication.
vpn	VPN authentication.
web	Captive portal authentication.
mac <macaddr>	MAC address of the user.
name <username>	Name for the user.
profile <aaa_profile>	AAA profile for the user.
role <role>	Role for the user.

Example

The following commands create a role that logs HTTPS traffic, then assign the role to a specific client:

```
(host) [mynode] (config) #ip access-list session log-https
(host) [mynode] (config-submode) #any any svc-https permit log
(host) [mynode] (config-submode) #user-role web-debug
```

```
(host) [mynode] (config-submode) #session-acl log-https
```

In enable mode:

```
(host) [mynode] (config) #aaa user add 10.1.1.236 role web-debug
```

Command History

aaa user clear-sessions

```
aaa user clear-sessions <ipaddr>
```

Description

This command clears any ongoing sessions that the client already had before being assigned a role with the `aaa user add` command.

Parameter	Description
<ip-addr>	IP address of the user.

Example

The following command clears ongoing sessions for a client:

```
(host) [mynode] (config) #aaa user clear-sessions 10.1.1.236
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Enable mode on Mobility Conductor.

aaa user delete

```
aaa user delete { |all|<ip-addr>|<ap-ip-addr>|ap-name|mac <macaddr>|name <username>|role <role>}
```

Description

This command allows you to manually delete clients, users, or roles. For example, if you used the `aaa user add` command to assign a user role to a client, you can use this command to remove the role assignment. Note that you must provide either AP name or AP IP address if you want to delete bridge-mode clients.

Starting from ArubaOS 8.6.0.0, this command can be executed from the Mobility Conductor using the `ipaddr <ipaddr>` and `mac <macaddr>` parameters.

Parameter	Description
all	Deletes all connected clients.
<ip-addr>	IP address of the client to be deleted.
<ap-ip-addr>	IP address of the AP to be deleted.
ap-name	Name of the AP to be deleted.
mac <macaddr>	MAC address of the client to be deleted.
name	Name of the client to be deleted.
role	Role of the client to be deleted.

Example

To delete a user role:

```
(host) [mynode] (config) aaa user delete role web-debug
```

To delete a bridge-mode client:

```
(host) [mynode] (config) aaa user delete ap-name ap303 mac 58:94:6b:31:d0:f0
```

To delete a user from Mobility Conductor:

```
(host) [mm] (config) aaa user delete mac 58:94:6b:31:d0:f0
```

Command History

Release	Modification
ArubaOS 8.6.0.0	This command can be executed from the Mobility Conductor using the <code>ip-addr<ip-addr></code> and <code>macaddr <macaddr></code> parameters.
ArubaOS 8.2.0.0	The <code>ip-addr</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

aaa user-del-req-timeout

aaa user-del-req-timeout <timeout value>

Description

This command is used to configure the user delete request timeout value. The previously entered CLI will be marked complete or timed out when the configured timeout value expires.

Parameter	Description
<timeout value>	Timeout value in minutes. Range: 1 to 30 Default: 5 minutes

Example

The following command configures the user delete request,

```
(host) [mynode] (config) #aaa user-del-req-timeout 10
```

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

aaa user fast-age

aaa user fast-age

Description

This command enables fast aging of user table entries.

When this feature is enabled, if a device comes up on the network with a different IP address, the old IP address of the device is immediately deleted. If the user fast-age feature is not configured, the Mobility Conductor retains up to two IPv4 and two IPv6 addresses per device , and these IPs are aged out only when the device becomes inactive.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

aaa user monitor

```
aaa user monitor <ipaddr>|off
```

Description

This command checks to see whether the attributes of an authenticated user differs from those in the SOS. It also installs a timer that polls the SOS every 60 seconds and checks the following:

- ACLs
- upstream bandwidth contract
- downstream bandwidth contract

Parameter	Description
<ipaddr>	IP address of the user whose attributes are being checked.
off	Disable aaa user monitoring.

Example

The following command checks user SOS attributes:

```
(host) [mynode] (config) #aaa user monitor 10.1.1.236
```

aaa user stats-poll

aaa user stats-poll <secs>

Description

This command enables user statistics polling. If enabled, ArubaOS will poll user data verify that user information in the datapath of the Mobility Conductor is in synchronization with the data in the authentication module of the Mobility Conductor.

Parameter	Description
<secs>	This command enables user statistics polling, and defines the time interval between polls. The supported range is 60-600 seconds.

Example

The following command enables user statistics polling with an interval of 10 minutes:

```
(host) ^[md] (config) aaa user stats-poll 600
```

Command History

aaa xml-api

```
aaa xml-api server <server_id>
  clone <server>
  default-authentication-role <role>
  key <key>
  no ...
```

Description

This command configures an external XML API server, which is used for authentication and subscriber management from external agents. This command configures an external XML API server. For example, an XML API server can send a blacklist/denylist request for a client to the managed device. The server configured with this command is referenced in the AAA profile for the WLAN (see [aaa profile on page 88](#)).

Parameter	Description
server	IP address of the external XML API server.
clone	Name of an existing XML API server configuration from which parameter values are copied.
default-authentication-role <role>	Name of the role to be assigned to users after completing XML server authorization.
key	Preshared key to authenticate communication between the Mobility Conductor and the XML API server.
no	Negates any configured parameter.

Example

The following configures an XML API server:

```
(host) ^[md] (config) aaa xml-api server 10.210.1.245
key qwerTYuiOP
```

acl-debug alias-rule-hits type

```
acl-debug alias-rule-hits type
  role <name>
  route <name>
  session <name>
```

Description

- Aruba7220 Series controllers support a maximum of 8192 entries in the ACE table.
- Aruba9000 Series and Aruba7000 Series controllers support a maximum of 16384 entries in the ACE table.

Issue this command under the supervision of Aruba technical support to enable the collection and display of advanced ACL debugging information.

This command allocates hits-indices for role, route, and session ACEs expanded in an ACE with aliases.

Parameter	Description
role <name>	Name of the role for which you want to record advanced debugging information.
route <name>	Name of the route for which you want to record advanced debugging information.
session <name>	Name of the session for which you want to record advanced debugging information.

The action command `acl-debug alias-rule-hits type <acl-type> <name>` is used to allocate hits-indices for expanded-ACEs, and clear the Consolidate-Hits flag in the ACE.

Expanded-ACEs refer to the ACEs expanded in Datapath as per the netdestination usage in the ACE.

The Consolidate-Hits flag is a new flag introduced in ArubaOS 8.8.0.0 and is used to conserve the hits-indices allocation. In ArubaOS 8.7.0.0, hits-indices were allocated to all expanded-ACEs. In Aruba 8.8.0.0, the default behavior is to avoid that allocation and allow the user to allocate using the debug commands. This is a behavior change in ArubaOS 8.8.0.0 and is done to conserve the hits-indices usage.

As this is a change in the ACL, Auth will download the ACEs and ACL to Datapath. The corresponding clear command `cmd - clear acl-debug alias-rule-hits type <acl-type> <name>` will reclaim the hits-indices allocated to the ACL, and re-download the ACEs and ACLs with the Consolidated-Hits flag set.

The action command could fail when a lot ACLs are being debugged and current system limits are exceeded. In that case, a failure message indicates that the hits-indices allocation for the ACL has failed.

The action commands in the examples below are to be executed only when an ACL is being debugged.

Examples

This section illustrates an example user-role with Consolidated-Hits set by default and hits-indices allocated during debugging.

ACL Hits debugging with Consolidated-Hits Flag set (default)

```
(host) [mynode] #show acl acl-table | include sacl-allow-internal,role1
101 session 925 1 2 sacl-allow-internal 0
102 session 0 0 1 apprf-role1-sacl 0

  username <username>
  whitelist download / allowlist download
  whitelist-enable / allowlist-enable
```

Description

This command synchronizes a managed device or a remote AP whitelist/allowlist on Mobility Conductor with the Activate whitelist/allowlist database. The Mobility Conductor and the Activate server must have layer-3 connectivity to communicate.

Parameter	Description
add-only	Allow only addition or modification of entries to the Activate remote AP whitelist/allowlist database. This parameter is enabled by default. If this setting is disabled, the activate-whitelist-download/activate-allowlist-download command can both add and remove entries from the Activate database.
ca-cert <cacert>	Use this command to manually upload self signed certificate and establish a trust relationship for a successful IPsec connection between the managed device and Activate server.
device-whitelist-enable / device-allowlist-enable	Use this command to enable managed device's whitelist/allowlist synchronization with the Activate server. This feature is disabled by default.
device-interval <frequency>	Number of hours between the automatic synchronization of the controller's whitelist/allowlist entries with the Activate server. The supported range is 1 - 168 hours.
get-activation-key	Issue this command to get activation key for the device.
interval <days>	Number of days between the automatic synchronization of the controller remote AP whitelist/allowlist entries with Activate. The supported range is 1-7 days, and the default value is 1 day.
no	Removes or disables an existing parameter.

Parameter	Description
password <password>	Activate user password.
provisionurl <provisionurlname>	Enter the URL of the page that provisions the devices to be managed by the Activate server. The default URL is https://devices.arubanetworks.com .
sync	Execute the activate sync command to immediately synchronize the list of managed devices on the Activate server with the managed device whitelist/allowlist on Mobility Conductor. By default, this list is synchronized every hour.
username <username>	Activate username.
url<urlname>	Enter the URL of the Activate server where users can provision and manage devices. The default URL is https://activate.arubanetworks.com .
whitelist download / allowlist download	Issue this command to download and synchronize Mobility Conductor's remote AP and managed device whitelist/allowlist from the Activate server.
whitelist-enable / allowlist-enable	Issue this command to enable secure remote AP and managed device whitelist/allowlist synchronization with the Activate service. This feature is disabled by default.

Example

The following example synchronizes the Activate whitelist/allowlist with the remote AP whitelist/allowlist on the controller:

```
(host) [mynode] (config) # activate whitelist download / allowlist download
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The following terminologies are updated: <ul style="list-style-type: none"> All instances of <code>master</code> have been replaced with <code>conductor</code>. All instances of <code>whitelist</code> have been replaced with <code>allowlist</code>.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor , except for the <code>whitelist/allowlist</code> <code>download</code> and <code>sync</code> parameters, which are available in enable mode only.

add ap arm client-match unsupported

```
add ap arm client-match unsupported <mac-addr>
```

Description

This command marks a station as unsupported by ClientMatch .

This is an internal command used to diagnose and debug ClientMatch issues, and should be used only under the supervision of customer support.

Parameter	Description
<mac-addr>	MAC address of the station to be ignored by ClientMatch.

Command History

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

adp

```
adp
  discovery
  igmp-join
  igmp-vlan <igmp-vlan-id>
```

Description

This command configures the ADP. Aruba APs send out periodic multicast and broadcast queries to locate Mobility Conductor. If the APs are in the same broadcast domain as Mobility Conductor and ADP is enabled on the managed device, the managed device automatically responds to the queries of APs with its IP address. If the APs are not in the same broadcast domain as Mobility Conductor, you need to enable multicast on the network. You also need to make sure that all routers are configured to listen for IGMP join requests from the managed device and can route the multicast packets. Use the `show adp config` command to verify that ADP and IGMP join options are enabled on the managed device.

Parameter	Description
discovery	Enables or disables ADP on the managed device. enabled
igmp-join	Enables or disables sending of Internet Group Management Protocol (IGMP) join requests from a managed device. enabled
igmp-vlan	VLAN to which IGMP reports are sent. 0

airmatch ap

```
airmatch ap freeze all-aps|[ap-group <ap-group>]|[ap-name <ap-name>]|[ip-addr <ip-addr>]|  
[ip6-addr <i6p-addr>] [band <band>] | [channel <channel>]| [eirp <dBm>]| [lms lms-ip  
<lms-ip>] | [lms-ipv6 <lms-ipv6>]
```

```
airmatch ap unfreeze all-aps|[ap-group <ap-group>]|[ap-name <ap-name>]|[ip-addr <ip-  
addr>]|[ip6-addr <i6p-addr>] band <band> | [channel <channel>]| [eirp <dBm>]| [lms lms-ip  
<lms-ip>] | [lms-ipv6 <lms-ipv6>]
```

Description

The `airmatch ap freeze` command deploys the specified channel and EIRP values to a radio immediately, then freezes those values, regardless of whether the AirMatch RF planning schedule is enabled or disabled. A radio set with the `airmatch ap freeze` command uses a static radio configuration until those settings get explicitly canceled with the `airmatch ap unfreeze` command. This command can be used to freeze either the channel or the EIRP value, or both values. For example, you can freeze the channel on an AP radio, while allowing the EIRP values to be updated by AirMatch.

Syntax

Parameter	Description
<code>freeze</code>	Apply the specified AirMatch settings on the radio, then freeze those settings until they are manually removed. This parameter supports both single radio and dual-radio APs.
<code>unfreeze</code>	Remove AirMatch settings manually applied using the Freeze command. This parameter supports both single radio and dual-radio APs.
<code>all-aps</code>	Freeze or unfreeze AirMatch settings on all APs.
<code>ap-group <ap-group></code>	Freeze or unfreeze AirMatch settings on the specified AP group
<code>ap-name <ap-name></code>	Freeze or unfreeze AirMatch settings on the specified AP
<code>ip-addr <ip-addr></code>	Freeze or unfreeze AirMatch settings on the AP with the specified IPv4 IP address.
<code>ip6-addr <i6p-addr></code>	Freeze or unfreeze AirMatch settings on the AP with the specified IPv6 IP address.
<code>band <band></code>	Set AirMatch settings for the specified radio band. Supported values are 2.4GHz and 5GHz . The radio band <i>must</i> be specified if you use the unfreeze parameter to unfreeze an AP radio. The values, 5GHzu for upper-band radios and 5GHzl for lower-band radios are supported by the following APs. <ul style="list-style-type: none">■ AP-344■ AP-345■ AP-555

Parameter	Description
channel <channel>	Channel number for the AP 802.11a/b/g, 802.11n or 802.11ac physical layer, (example: 1, 1+, 36, 36+, 36E, 36S, 36E+149E). The available channels depend on the regulatory domain (country). <ul style="list-style-type: none"> ■ 36S is 160 MHz wide contiguous channel ■ 36E+149E is 160 MHz wide channel defined as 2 separate 80 MHz channel ranges
eirp <dBm>	The transmission power level (in dBm) to be assigned to the AP radio(s). Starting with ArubaOS 8.2, you can specify EIRP values in increments of .1 dBm. 270 Series access points support both positive and negative EIRP values. All other APs support positive EIRP values only. The following legacy APs do <i>not</i> support advanced power controls, and can only be configured in positive EIRP values in increments of .5 dBm. <ul style="list-style-type: none"> ■ 90 Series ■ 100 Series ■ 110 Series ■ 170 Series ■ RAP-155
lms lms-ip <lms-ip> lms-ipv6 <lms-ipv6>	Include this parameter to freeze or unfreeze AP channels on a local controller. This parameter is only valid if you freeze or unfreeze channels using the ap-group or all-aps options.

Example

```
(host)[mynode](config)# airmatch ap freeze {ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}|{ap-name <ap-name>}|{ap-group <ap-group>}|{all-aps} {band <band>}|{channel <channel>}|{eirp <eirp>}|lms {lms-ip <lms-ip>}|{lms-ipv6 <lms-ipv6>}}
```

Unfreezing a radio configuration with the `airmatch ap unfreeze` command does not mean that there will automatically be an immediate change in the channel and EIRP values for that radio. It does, however, mean that the AirMatch algorithm can assign a new set of values at the next update.

```
(host)[mynode](config)# airmatch ap unfreeze {ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}|{ap-name <ap-name>}|{ap-group <ap-group>}|{all-aps} band <band> {channel <channel>}|{eirp <eirp>}|lms {lms-ip <lms-ip>}|{lms-ipv6 <lms-ipv6>}}
```

airmatch db-dump

```
airmatch db-dump  
all  
collection
```

Description

This command creates a dump of the database used by AirMatch. The dump file can be exported using the **copy** command.

Parameter	Description
all	Create a dump file of the entire AirMatch database
collection <collection>	Create a dump file of a specific collection of AirMatch files by specifying the name of a collection type.

Example

The following command creates a dump file of the collection of AirMatch AMON statistics.

```
(host)[mynode]# airmatch db-dump all
```

```

Description

This command configures the AirMatch profile.

The AirMatch channel and EIRP optimization features deprecate the channel planning and EIRP optimization features in the legacy ARM feature. AirMatch is supported on Mobility Conductor only, while legacy ARM channel optimization and EIRP features continue to be supported by stand-alone controllers running ArubaOS 8.x.

AirMatch channel planning evens out channel distributions in any size of network, and in any subset of the contiguous network (as much as allowed by the network configuration, regulatory domain and AP hardware capability). AirMatch also minimizes channel coupling, where adjacent radios are assigned to the same channel. The computing power of Mobility Conductor impacts channel distribution calculations, so channel coupling may occasionally be allowed in complex networks to keep the computing time practical.

AirMatch EIRP planning automatically considers the local density of the network to manage the APs' coverage and modulation and coding scheme (MCS) operation, and optimizes EIRP changes across neighboring AP radios in order to offer users the best roaming experience.

The AirMatch **schedule disable** setting is different from the ARM setting of **disable** or **maintain**. The ARM **disable** setting changes the AP radio channel and EIRP values back to the default values specified in 802.11a and 802.11g radio profiles for that radio. The ARM **maintain** setting freezes current channel and EIRP settings for that radio. In contrast, the AirMatch **schedule disable** option simply means the centralized algorithm will stop selecting a new channel, bandwidth, or EIRP setting; the network operator still can override the previous settings assigned by AirMatch with static channel or EIRP values, and the AP radio can continue to voluntarily change channels to avoid radar interference or high noise levels.

AirMatch Channel Assignments

Each AP in a Mobility Conductor deployment measures its RF environment for a five minute period, every 30 minutes, by default. The AP then sends AMON messages about the radio feasibility to the managed device based on the hardware capability for the AP, radio and regulatory domain, and RF neighbors. The managed device forwards these messages to the Mobility Conductor. The Mobility Conductor adds this information to a database, computes an optimal solution, and deploys the latest RF plan by sending updated settings to the APs. By default, this configuration update is sent at 5 AM (as per

the Mobility Conductor system clock), but time of this configuration update can be modified via the AirMatch profile.

An exception to this daily update is an automatic channel change due to a radar detection event or high noise interference. If an AP detects a radar event on its current operating channel, that AP automatically changes to another supported channel to avoid radar interference, and does not wait for the daily RF configuration update from the Mobility Conductor. An AP may also automatically change channels if a very high noise level is detected on the current channel, if at least one other channel is free of noise.

In ArubaOS 8.0, AirMatch moves a radio to a random channel when a radar event is detected, or if a high noise floor is detected on a non-static channel. Starting with ArubaOS 8.0.1, AirMatch uses the criteria described in [Table 6](#) to assign a new channel.

Table 6: Channel Assignment Logic

Issue Prompting Channel Change	Channel Selection Criteria
Detected radar	AirMatch selects a channel with a minimum interference index from the channels without high noise or a radar condition.
High channel noise	<p>The channel selection criteria varies between static and non-static channels.</p> <ul style="list-style-type: none"> ■ If static channel is configured, the channel does not change due to a high noise condition. ■ For a non-static channel, AirMatch selects a channel with a minimum interference index from the channels without high noise or a radar condition.

Channel Quality Improvement Thresholds

ArubaOS 8.0.1 introduces the AirMatch channel quality improvement threshold, which allows you to select the minimum channel improvement that can trigger a new scheduled channel solution. The default threshold value is a 15% improvement. If a proposed channel change will not produce an improvement that meets or exceeds this threshold, AirMatch will not trigger a channel change.

EIRP settings are not impacted by the channel quality improvement threshold. A new EIRP plan is deployed at the scheduled deployment hour every day, regardless of channel quality improvement levels.

This channel quality setting only applies to scheduled updates. If you manually trigger an update using the `airmatch runnow` command, AirMatch will deploy the new solution regardless of the level of improvement.

Parameter	Description
deploy-hour <0-23>	<p>Specify a number from 0-23 to select the hour during which AirMatch updates are sent to the APs (in 24-hour format). If the managed device to which the AP is associated is in a different time zone than Mobility Conductor, the AirMatch solution will be deployed according to the time zone of the managed device. If this parameter is set in both the AirMatch profile and the 802.11a radio profile, the setting in the 802.11a radio profile will take precedence.</p> <p>0-23 5</p>

Parameter	Description
he-pooling-client-density <he-pooling-client-density>	Specify a HE pooling client density in percentage to be considered for 802.11ax pooling. Va HE pooling client density of 0 disables HE pooling. 0-100 20
dfs-ch-deploy-interval	Configures the time interval (in minutes) between the deployment of radios assigned to operate on DFS channels. 0,1 0
no ...	Negates any configured parameter
noise-event-period-2g <noise-event-period-2g>	Use this advanced configuration parameter under the supervision of Aruba support only.
noise-event-period-5g <noise-event-period-5g>	Use this advanced configuration parameter under the supervision of Aruba support only.
quality-threshold <quality-threshold>	Use the <code>quality-threshold</code> parameter to change the percentage of channel quality improvement that will trigger an AirMatch RF update. If a proposed channel change will not produce an improvement that meets or exceeds this threshold, AirMatch will not trigger a channel change. This setting only applies to scheduled updates. If you manually trigger an update using the <code>airmatch runnow</code> command, AirMatch will deploy the new solution regardless of the level of improvement. If scheduled updates are enabled, the new channel plan is deployed on the specified deployment hour only if it is improved by greater than this threshold value. A new EIRP plan is deployed on the deployment hour every day. 0-100 8
quality-threshold-2-4GHz	Use the <code>quality-threshold-2-4GHz</code> parameter to change the percentage of 2.4 GHz channel quality improvement that will trigger an AirMatch RF update. If a proposed channel change will not produce an improvement that meets or exceeds this threshold, AirMatch will not trigger a channel change. This setting only applies to scheduled updates. If you manually trigger an update using the <code>airmatch runnow</code> command, AirMatch will deploy the new solution regardless of the level of improvement. If scheduled updates are enabled, the new channel plan is deployed on the specified deployment hour only if it is improved by greater than this threshold value for 2.4 Ghz radio. A new EIRP plan is deployed on the deployment hour every day. 0-100 8

Parameter	Description
quality-threshold-5GHz	<p>Use the <code>quality-threshold-5GHz</code> parameter to change the percentage of 5 GHz channel quality improvement that will trigger an AirMatch RF update. If a proposed channel change will not produce an improvement that meets or exceeds this threshold, AirMatch will not trigger a channel change.</p> <p>This setting only applies to scheduled updates. If you manually trigger an update using the <code>airmatch runnow</code> command, AirMatch will deploy the new solution regardless of the level of improvement.</p> <p>If scheduled updates are enabled, the new channel plan is deployed on the specified deployment hour only if it is improved by greater than this threshold value for 2.4 Ghz radio. A new EIRP plan is deployed on the deployment hour every day.</p> <p>0-100 8</p>
quality-threshold-6GHz	<p>Use the <code>quality-threshold-6GHz</code> parameter to change the percentage of 6 GHz channel quality improvement that will trigger an AirMatch RF update. If a proposed channel change will not produce an improvement that meets or exceeds this threshold, AirMatch will not trigger a channel change.</p> <p>This setting only applies to scheduled updates. If you manually trigger an update using the <code>airmatch runnow</code> command, AirMatch will deploy the new solution regardless of the level of improvement.</p> <p>If scheduled updates are enabled, the new channel plan is deployed on the specified deployment hour only if it is improved by greater than this threshold value for 2.4 Ghz radio. A new EIRP plan is deployed on the deployment hour every day.</p> <p>0-100 8</p>
radar-event-period-5g <radar-event-period-5g>	<p>Use this advanced configuration parameter under the supervision of Aruba support only.</p>
schedule enabled disabled	<p>If the AirMatch schedule updates are changed from the default enabled setting to disabled, the Mobility Conductor continues to receive RF updates from the APs, but no channel and EIRP changes are executed by Mobility Conductor at the scheduled time.</p> <p>When AirMatch schedules are disabled, the centralized algorithm stops selecting a new channel, bandwidth, stops EIRP setting. A network operator still can override the previous settings assigned by AirMatch with static channel or EIRP values, and the AP radio can continue to voluntarily change channels to avoid radar interference or high noise levels.</p> <p>enabled</p>
solver-feas-deploy-threshold <solver-feas-deploy-threshold>	<p>Use this advanced configuration parameter under the supervision of Aruba support only.</p>
use-intf-device	<p>Enable this configuration to include interferer in the RF-domain and partition computation .</p> <p>Disabled</p>

Parameter	Description
	CAUTION: Enabling this parameter will highly impact AirMatch solution.

Example

To hold the existing AirMatch RF configuration :

```
(host) [mynode] (config) # airmatch profile schedule disabled
```

To change the time of the daily AirMatch RF updates from the default 5 AM to 2 AM:

```
(host) [mynode] (config) # airmatch profile deploy-hour 2
```

Related Commands

Command	Description
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.
airmatch db-dump	This command creates a dump of the database used by AirMatch. The dump file can be exported using the <code>copy</code> command.
airmatch runnow	Manually initiate AirMatch RF computations and solution deployment instead of waiting for the next scheduled update period.
show airmatch profile	This command displays the configuration settings in the AirMatch profile.

Command History

Release	Modification
ArubaOS 8.10.0.0	The dfs-ch-deploy-interval parameter was introduced.
ArubaOS 8.7.0.0	The <code>he-pooling-client-density</code> parameter was introduced.
ArubaOS 8.2.1.0	The default value of the <code>quality-threshold</code> parameter was changed to 8%.
ArubaOS 8.1.0.0	The <code>eirp-offset</code> parameter was removed from this command, and was introduced in rf dot11a-radio-profile and rf dot11g-radio-profile commands.

Release	Modification
ArubaOS 8.0.1.0	The <code>quality-threshold</code> parameter was added.
ArubaOS 8.0.0.0	This command was introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Configuration mode on Mobility Conductor.

airmatch runnow

```
airmatch runnow
  eirp
  full
  incremental
  opmode
  quick
```

Description

Manually initiate AirMatch RF computations and solution deployment instead of waiting for the next scheduled update period.

Parameter	Description
<code>eirp</code>	Initiates only the EIRP optimization.
<code>full</code>	Initiate the process to perform a full optimization of all APs.
<code>incremental</code>	Optimize only the new APs that have never been optimized by a previous AirMatch solution.
<code>opmode</code>	Generate an AirMatch solution with an opmode update.
<code>quick</code>	Quickly generate an AirMatch solution. This option may produce an AirMatch solution that is not as optimal as a full or regularly-scheduled optimization.

Example

To initiate a full optimization of all APs, access the Mobility Conductor CLI in enable mode and issue the following command:

```
(host)[mynode] #airmatch runnow full
```

Related Commands

Command	Description
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.
airmatch profile	This command configures the AirMatch profile.

Command History

Release	Modification
ArubaOS 8.3.0.0	The following parameters were introduced: <ul style="list-style-type: none"> ■ eirp ■ opmode
ArubaOS 8.0.0.0	Command introduced.

Command Information

airslice

```
airslice-profile <profile-name>
  airslice-app-monitoring
  airslice-policy
  clone
  no
airslice-visibility
  record-limit <record-count>
  record-limit unlimited
```

Description

This command configures or modifies an Air Slice profile.

Parameter	Description
airslice-profile <profile-name>	Configure the Air Slice profile.
airslice-app-monitoring	Enables traffic monitoring for applications.
airslice-policy	Optimizes the community quality of applications.
clone	Copies data from another Air Slice profile.
no	Deletes the profile.
airslice-visibility	Configure the Air-Slice visibility module.
record-limit <record-count>	Specify the maximum number of records to be stored for clients.
record-limit unlimited	No limit on the number of records to be stored for clients. All records are stored.

Example

The following command configures an Air Slice profile:

```
(host) [mynode] (config) #airslice-profile <name>
(host) [mynode] (airslice profile <name>) airslice-app-monitoring
(host) [mynode] (airslice profile <name>) airslice-policy
```

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Air Slice is supported on all 802.11ax APs. However, Air Slice is supported only on 5 GHz radio and not on 6 GHz radio for 630 Series access points.	Base operating system.	Config mode on Mobility Conductor.

ale-configuration

```
ale-configuration
  ale_sta_associated
  anonymize
  ip <ip-addr> username <uname> password <passwd>
  nbapi_publish
```

Description

Use this command to enable ALE configuration. After ALE is enabled, you can configure ALE anonymize, STA channel, IP address, and NB API.

Parameter	Description
ale_sta_associated	Publish ALE_STA channel for associated clients only.
anonymize	Station Mac Anonymization.
ip	VLAN to which IGMP reports are sent.
nbapi_publish	Enable publishing of data available via zmq, including station, virtual AP, AP, radio, RSSI, visibility_rec, destination, application; and REST API including details about floor, campus, building, Virtual AP, AP, station, radio.
no	Disable ALE on the Mobility Conductor.

Example

To enable ALE configuration:

```
(host) [mynode] (config) #ale-configuration
```

To enable anonymize in ALE:

```
(host) [mynode] (config) #ale-configuration
(host) [mynode] (config-submode) #anonymize
```

whitelist-db cpsec add / allowlist-db cpsec add

```
whitelist-db cpsec add / allowlist-db cpsec add
mac-address <name>
  ap-group <ap_group>
  ap-name <ap_name>
  description <description>
```

Description

This command adds an AP entry to the campus AP whitelist/allowlist.

You can manually add entries to the campus AP whitelist/allowlist to grant valid APs secure access to the network.

Parameter	Description
mac-address <name>	MAC address of the AP you want to enter into the campus AP whitelist/allowlist database.
ap-group <ap_group>	(Optional) Name of the AP group. If the AP group is not entered, a campus AP boots with "default" as AP group.
ap-name <ap_name>	(Optional) Name of the AP. If the AP name is not entered, a campus AP boots with its MAC address as AP name.
description <description>	(Optional) Brief description of the AP. If the description includes spaces, enclose the description in quotation marks.

Example

The following example creates a new campus AP whitelist/allowlist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host) #whitelist-db cpsec add mac-address 00:16:CF:AF:3E:E1 / allowlist-db
cpsec add mac-address 00:16:CF:AF:3E:E1
ap-group default
ap-name AP-225
description "AP-225 in lobby"
```

Related Command

whitelist-db cpsec del / allowlist-db cpsec del

```
whitelist-db cpsec del / allowlist-db cpsec del mac-address <mac-address>
```

Description

This command removes individual whitelist/allowlist entries for an AP that has been either removed from the network, or is no longer a candidate for automatic certificate provisioning. If the AP whose entry you deleted is still connected to the network and the control plane security feature is configured to send certificates to all APs (or a range of addresses that include that AP), then the managed device will send the AP another certificate, and the AP will reappear in the campus whitelist/allowlist.

Parameter	Description
<code>mac-address <mac-address></code>	MAC address of the AP you want to remove from the campus AP whitelist/allowlist.

Example

The following example removes an AP with the MAC address 10:14:CA:AF:3E:E1 from the campus AP whitelist/allowlist:

```
(host) [mynode] (config) #whitelist-db cpsec del mac-address  
10:14:CA:AF:3E:E1/allowlist-db cpsec del mac-address 10:14:CA:AF:3E:E1
```

Related Commands

Command	Description
show whitelist-db cpsec/show allowlist-db cpsec	Show the campus AP whitelist/allowlist for the control plane feature.
whitelist-db cpsec revoke / allowlist-db cpsec revoke	Revoke a certificate from an invalid or suspected rogue AP in the campus AP whitelist/allowlist.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>whitelist</code> have been replaced with <code>allowlist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode

whitelist-db cpsec modify / allowlist-db cpsec modify

```
whitelist-db cpsec modify / allowlist-db cpsec modify
  mac-address <name>
  ap-group <ap_group>
  ap-name <ap_name>
  cert-type {factory-cert|switch-cert}
  description <description>
  mode {disable|enable}
  revoke-text <revoke-text>
  state {approved-ready-for-cert|certified-factory-cert}
```

Description

This command modifies an existing entry in the campus AP whitelist/allowlist.

Parameter	Description
mac-address <name>	MAC address of an AP in the campus AP whitelist/allowlist database.
ap-group <ap_group>	(Optional) Name of the AP group to which an AP is assigned. If AP group is not entered, a campus AP boots with "default" as the AP group.
ap-name <ap_name>	(Optional) Name of an AP. If AP name is not entered, a campus AP boots with its MAC address as the AP name.
cert-type {factory-cert switch-cert}	(Optional) Type of certificate used by an AP. <ul style="list-style-type: none">■ factory-cert: AP uses a factory-installed certificate.■ switch-cert: AP uses a controller-signed certificate.
description <description>	(Optional) Brief description of an AP. If the description includes spaces, enclose the description in quotation marks.
mode {disable enable}	(Optional) Mode of an AP. <ul style="list-style-type: none">■ disable: Disables an AP in the campus AP whitelist. A disabled AP cannot contact a managed device over a secure connection.■ enable: Enables a disabled AP in the campus AP whitelist/allowlist.
revoke-text <revoke-text>	(Optional) Brief description why an AP was revoked.
state {approved-ready-for-cert certified-factory-cert}	(Optional) State of an AP. <ul style="list-style-type: none">■ approved-ready-for-cert: AP is approved and is ready to receive a certificate.■ certified-factory-cert: AP is certified and has a factory-installed certificate.

Example

The following example changes the AP group, AP name, certificate type, description, mode, revoke text, and state of an AP with MAC address 00:1E:37:CB:D4:52:

```
(host)[node] #whitelist-db cpsec modify mac-address 00:1E:37:CB:D4:52/  
allowlist-db cpsec modify mac-address 00:1E:37:CB:D4:52  
    ap-group default  
    ap-name ap-225  
    cert-type factory-cert  
    description "AP-225 in lobby"  
    mode disable  
    revoke-text "Maintenance"  
    state approved-ready-for-cert
```

Related Command

whitelist-db cpsec purge / allowlist-db cpsec purge

whitelist-db cpsec purge / allowlist-db cpsec purge

Description

This command clears all entries in the campus AP whitelist/allowlist.

If your network includes both Mobility Conductor and managed devices, then each campus AP whitelist/allowlist is synchronized across all managed devices. If you purge the entire list on one managed device, that action will clear the campus AP whitelist/allowlist on every managed device in the network. To delete an individual entry, use the command [whitelist-db cpsec del / allowlist-db cpsec del](#).

Example

The following example removes all APs from the campus AP whitelist/allowlist:

```
(host)[node] (config) #whitelist-db cpsec purge/allowlist-db cpsec purge
```

Related Command

whitelist-db cpsec revoke / allowlist-db cpsec revoke

```
whitelist-db cpsec revoke / allowlist-db cpsec revoke mac-address <mac-address>  
revoke-text <revoke-text>
```

Description

This command revokes a certificate from an AP in the campus AP whitelist/allowlist. Use this command to revoke a certificate from a invalid or suspected rogue AP.

Parameter	Description
mac-address <mac-address>	MAC address of the AP you want to remove from the cpsec whitelist/allowlist database.
revoke-text <revoke-text>	A brief description why the AP's certificate was revoked, up to 64 alphanumeric characters. If this comment includes spaces, you must enclose the comment in quotation marks.

Example

The following example revokes a certificate from an AP. This command does not delete a whitelist/allowlist entry for a revoked AP, but marks its entry with the revoked state.

```
(host)[node] (config) #whitelist-db cpsec revoke mac-address  
00:1E:37:CA:D4:51 / allowlist-db cpsec revoke mac-address 00:1E:37:CA:D4:51  
revoke-text "revoking cert from a rogue AP."
```

Related Command

Command	Description
show whitelist-db cpsec/show allowlist-db cpsec	Show the campus AP whitelist/allowlist for the control plane feature.

whitelist-db rap add /allowlist-db rap add

```
whitelist-db rap add /allowlist-db rap add mac-addr <mac-address>
  ap-group <ap-group>
  ap-name <ap-name>
  description <description>
  full-name <full-name>
  mode enable|disable
  remote-ip <ip-addr>
```

Description

This command adds an AP entry to the Remote AP whitelist/allowlist. You can manually add entries to the remote AP whitelist/allowlist to grant valid Remote APs secure access to the network.

Parameter	Description
mac-address <mac-address>	MAC address of the AP you want to enter into the remote AP whitelist/allowlist database.
ap-group <ap-group>	AP group of the remote AP.
ap-name <ap-name>	Name of the Remote AP.
description <description>	Description of the remote AP. If the description includes spaces, it must be enclosed within quotation marks.
full-name <full-name>	Name of the client using the remote AP.
remote-ip <ip-addr>	IP address used to assign a static inner IP address for the remote AP.

Example

The following example creates a new Remote AP whitelist/allowlist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host)[node](config) #whitelist-db rap add mac-address 00:16:CF:AF:3E:E1 /
allowlist-db rap add mac-address 00:16:CF:AF:3E:E1
```

  ap-name <ap-name>
  description <description>
  full-name <full-name>
  mode enable|disable
  remote-ip <ip-addr>
  remote-ipv6 <ipv6-addr>
```

Description

This command removes an AP entry from the Remote AP whitelist/allowlist.

You can manually remove entries from the Remote AP whitelist/allowlist to revoke a Remote AP's secure access to the network.

Parameter	Description
mac-address <mac-address>	MAC address of the remote AP whose whitelist/allowlist database entry you want to modify.
ap-group <ap-group>	AP group of the remote AP.
ap-name <ap-name>	Name of the Remote AP.
description <description>	Description of the remote AP. If the description includes spaces, it must be enclosed within quotation marks.
full-name <full-name>	Name of the client using the remote AP.
mode enable disable	Enable or disable the remote AP without deleting it from the database.
remote-ip <ip-addr>	IPv4 address used to assign a static inner IP address for the remote AP.
remote-ipv6 <ipv6-addr>	IPv6 address used to assign a static inner IP address for the remote AP.

Example

The following example modifies a Remote AP whitelist/allowlist entry for an AP with the MAC address 00:16:CF:AF:3E:E1:

```
(host)[node] (config) #whitelist-db rap modify mac-address 00:16:CF:AF:3E:E1
/ allowlist-db rap modify mac-address 00:16:CF:AF:3E:E1
description "AP moved to second floor"
```

whitelist-db rap revoke/allowlist-db rap revoke

```
whitelist-db rap revoke/allowlist-db rap revoke mac-address <mac-address> revoke-  
comment <comment>
```

Description

This command revokes a certificate from an AP in the Remote AP whitelist/allowlist . Use this command to revoke a certificate from a invalid or suspected rogue AP.

Parameter	Description
mac-address <mac-address>	MAC address of the AP you want to remove from the remote AP whitelist/allowlist database.
revoke-comment <comment>	A brief description why the AP's certificate was revoked, up to 64 alphanumeric characters. If this comment includes spaces, you must enclose the comment in quotation marks.

Example

The following example revokes a certificate from an AP. This command does not delete a whitelist/allowlist entry for a revoked AP, but marks its entry with the revoked state.

```
(host) (config) #whitelist-db rap revoke mac-address 00:1E:37:CA:D4:51 /  
allowlist-db rap revoke mac-address 00:1E:37:CA:D4:51  
revoke-comment "revoking cert from a rogue RAP."
```

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>whitelist</code> have been replaced with <code>allowlist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

whitelist-db rap-local-switch-list/allowlist-db rap-local-switch-list

```
whitelist-db rap-local-switch-list/allowlist-db rap-local-switch-list
  del mac-addr <mac-address>
  purge
```

Description

This command deletes a managed device from the local switch table used by the Remote AP whitelist/allowlist.

If your deployment includes Mobility Conductor and managed devices, then the remote AP whitelist/allowlist on each managed device contains an entry for every remote AP on the network, regardless of the managed device to which it is connected. Mobility Conductor also maintains a whitelist/allowlist managed devices with remote AP. When you change a remote AP whitelist/allowlist on any managed device, that managed device contacts Mobility Conductor to check the local switch whitelist/allowlist, then contacts every other managed device on the local switch whitelist/allowlist to notify it of the change.

If you ever remove a managed device from the network, you must also remove the managed device from the local switch whitelist/allowlist. If the local switch whitelist/allowlist contains entries for managed devices no longer on the network, then a remote AP whitelist/allowlist entry can be marked for deletion but will not be physically deleted, as the managed device will be waiting for an acknowledgment from another managed device no longer on the network. Any unused managed device entries in the local switch whitelist/allowlist can significantly increase network traffic and reduce memory resources.

Parameter	Description
<code>del mac-address <mac-address></code>	Remove a single managed device from the local switch table.
<code>purge</code>	Clear all managed devices from the local switch table

Example

The following example removes a managed device from the local switch whitelist/allowlist table:

```
(host)[node] (config) #whitelist-db rap-local-switch-list del mac-address
00:16:CF:AF:3E:E1 / allowlist-db rap-local-switch-list del mac-address
00:16:CF:AF:3E:E1
```

Related Command

Command	Description
whitelist-db rap add /allowlist-db rap add	Add an entry into the remote AP whitelist/allowlist.

whitelist-db rap-master-switch-list/allowlist-db rap-master-switch-list

```
whitelist-db rap-master-switch-list /allowlist-db rap-master-switch-list
  del mac-addr <mac-address>
  purge
```

Description

This command deletes a Mobility Conductor from the master/conductor switch table used by the Remote AP whitelist/allowlist.

Each managed device with Remote APs managed through a Remote AP whitelist/allowlist has a master/conductor switch whitelist/allowlist which contains the IP and MAC addresses of its Mobility Conductor. If your network has a redundant Mobility Conductor, then this list will contain more than one entry.

Though you can delete an entry from the master/conductor switch whitelist/allowlist, you should do so only if you have removed a master/conductor switch from the network. Deleting a valid Mobility Conductor from the master/conductor switch whitelist/allowlist can cause errors in your network.

Parameter	Description
<code>del mac-address <mac-address></code>	Remove a single Mobility Conductor from the master/conductor whitelist/allowlist.
<code>purge</code>	Clear all Mobility Conductors from the Registered master/conductor switch table.

Example

The following example removes a Mobility Conductor from the master/conductor switch whitelist/allowlist table:

```
(host) [node] (config) #whitelist-db rap-master-switch-list del mac-address
00:16:CF:AF:3E:E1 / allowlist-db rap-master-switch-list del mac-address
00:16:CF:AF:3E:E1
```

Related Command

Command	Description
whitelist-db rap add /allowlist-db rap add	Add an entry into the remote AP whitelist/allowlist.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>whitelist</code> have been replaced with <code>allowlist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

allowed-address-list

```
allowed-address-list  
  ipv4  
  ipv6
```

Description

This command configures addresses exempted when the deny-inter-user-bridging is enabled.

Parameter	Description
ipv4	This parameter specifies the IPv4 address to be added to the allowed address list.
ipv6	This parameter specifies the IPv6 address to be added to the allowed address list.

Example

```
(host) [mynode] #allowed-address-table ipv4 10.12.133.14  
(host) [mynode] #allowed-address-table ipv4 10.12.133.15
```

Related Commands

Command	Description
no allowed-address-list	This command is used to remove the IP addresses that were added using allowed-address-list command.
show allowed-address-list	This command displays the list of allowed addresses that are exempted.

```

Description

The `scan` sub-command enables channel scanning for the specified air monitor. In addition, the `test` sub-command enables the client to test an air monitor. These commands are intended to be used with an AP that is configured as an air monitor.

Parameter	Description
<code>scan</code>	Enable or disable channel scan.
<code>ip-addr <ip-addr></code>	IP address of the air monitor to be scanned.
<code><channel></code>	Channel to which the scanning is tuned. Set to 0 to enable scanning of all channels.
<code>band</code>	Specify the band value from one of the following: <ul style="list-style-type: none">2.4 GHz

Parameter	Description
	<ul style="list-style-type: none"> 5 GHz 6 GHz
<code>bssid <bssid></code>	BSSID of the air monitor.
<code>test</code>	Enables the client to test an air monitor.
<code>ip-addr <ip-addr></code>	IP address of the air monitor.
<code>auto-device-creation</code>	<p>Sets the AP mode to add a monitored device and client at every interval.</p> <ul style="list-style-type: none"> start stop <p>Intervals are written as time in seconds.</p>
<code>interval <interval></code>	Sets the interval in seconds at which the new AP and client devices are added.
<code>phy-type {80211a 80211g}</code>	<p>Sets the band of the device.</p> <ul style="list-style-type: none"> 80211a for <i>a</i> band 80211g for <i>g</i> band
<code>create-device {ap client}</code>	<p>Creates an AP or client device.</p> <ul style="list-style-type: none"> ap client
<code>phy-type {80211a 80211g}</code>	<p>Specifies the band for the device.</p> <ul style="list-style-type: none"> 80211a 80211g
<code>bssid <bssid></code>	Specifies the bssid of the new device
<code>mac <mac></code>	Specifies the wired-mac address of the new device
<code>ev-gen</code>	Create an IDS event from the AP.
<code>event_id <event-id></code>	Specifies the event id to generate for the event.
<code>trap_id <trap_id></code>	<p>Specifies the trap id to generate or use 65535 if there are no traps. The various trap IDs are explained here:</p> <ul style="list-style-type: none"> ADDITIONAL_INFO—Additional information for syslog ADDRESS_TYPE—Address type (an integer because it is enum) AP_CHANNEL—Detecting AP channel or target channel AP_LOCATION—Detecting AP Name

Parameter	Description
	<ul style="list-style-type: none"> ▪ AP_MAC_ADDRESS—Detecting AP MAC ▪ AP_RADIO_NUM—Detecting AP Radio ▪ ASSOCIATION_TYPE—Association Type ex. Association To Rogue ▪ CONF_LEVEL—Confidence level of suspected rogue (5-100) ▪ FRAME_TYPE—Frame type (an integer because it is enum) ▪ INTERFERING_AP_INFO_URL—URL ▪ MATCHED_IP—Matched IP for classification ▪ MATCHED_MAC—Matched MAC for classification ▪ NODE_MAC—Node MAC ▪ RECEIVER_MAC—Receiver MAC ▪ ROGUE_INFO_URL—URL ▪ SIGNATURE_NAME—Name of signature matched ▪ SNR—Signal-to-Noise Ratio ▪ SOURCE_MAC—Source MAC ▪ SPOOFED_FRAME_TYPE—Spoofed Frame type (EAP Success) ▪ TARGET_AP_BSSID—Target AP BSSID ▪ TARGET_AP_SSID—Target AP SSID ▪ TRANSMITTER_MAC—Transmitter MAC
fake-noise	Generate fake noise floor value.
rap-ack-responses	Enable or disable rap ack responses for an AP.
rssi	Test RSSI.
suspect-rap	Test the suspect remote AP feature.
bssid <bssid>	Specifies the BSSID of monitored AP.
match-type <match-type>	Specifies the match type.
match-method <match-method>	Specifies the match method.
wired-mac {add remove}	Tests the rogue AP classification feature. Specifies the wired MAC table.
bssid <BSSID> mac <mac>	Specifies BSSID of monitored AP and wired-MAC address.
enet-mac <enet-mac> mac <mac>	MAC address of ENET interface of AP and wired-MAC address.

Parameter	Description
<code>prop-wm mac <mac></code>	Specifies the propagate wired-MAC
<code>system-gw-wm mac <mac></code>	Specifies the system gateway MAC.
<code>system-wm mac <mac></code>	Specifies the system wired-MAC.
<code>zero-wait-dfs</code>	Start or stop zero wait DFS testing for an AP.

Example

The following command sets the air monitor to scan all channels:

```
(host) (config) #am scan 10.1.1.244 0
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

amon cert

```
amon cert <cert-name>
```

Description

This command specifies the certificate name for Amon secure.

Parameter	Description
<code><cert-name></code>	Specify the certificate name.

Example

The example below enables AMON UDP.

```
(host) [mynode] (config) #amon cert
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

amon msg-buffer-size

amon msg-buffer-size <msg-buffer-size>

Description

This command modifies the size of AMON packets on the managed device.

Parameter	Description
<msg-buffer-size>	The size of AMON packets on the managed device. 1152-40000 1264

Example

The following command caps the AMON message size at 1500 bytes:

```
(host) [mynode] (config) #amon msg-buffer-size 1500
```

Related Commands

Release	Modification
show amon msg-buffer-size	Displays the size of AMON packets on the managed device.

Command History

Release	Modification
ArubaOS 8.1.0.0	The <code>msg-buffer-size</code> range was modified.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

amon source-interface

```
amon source-interface <vlan-num>
```

Description

This command specifies the IPv4 address of the VLAN as the source IP address.

Parameter	Description
<vlan-num>	The IPv4 address of the VLAN.

Example

The following example sets the VLAN number.

```
(host) [mynode] (config) #amon source-interface <vlan-num>
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

amon udp

[no] amon udp

Description

Enable the AirWave server to allow traffic on UDP port 8211.

Issue the `no amon udp` command to disable AMON UDP and re-enable it again using the command `amon udp`.

Example

The example below enables AMON UDP.

```
(host) [mynode] (config) #amon udp
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

ap am-filter-profile

```
ap am-filter-profile {default | <profile-name>}
  allow-ap-group
  allow-self
  ap-group <ap-group>
  ap-name <ap-name>
  clone
  filter-enable
  no
```

Description

This command configures an AM filter.

Parameter	Description
am-filter-profile <profile-name>	Name of this instance of the profile
allow-ap-group	Allows all APs in the same group as the AP
allow-self	Allows AP to hear its own frames
ap-group <ap-group>	Allows all APs in the group
ap-name <ap-name>	Name of AP to allow
clone {default <source>}	Copy data from another AM filter
filter-enable	Enable AM filtering
no	Delete command

Example

The following command allows AM filtering for all APs in the test1 group:

```
(host) [mynode] (config) #ap am-filter-profile test
(host) [mynode] (AM Filter "test") #ap-group test1
```

Command History

Release	Modification

ap ap-blacklist-time / ap ap-denylist-time

```
ap ap-blacklist-time <ap-blacklist-time>/ap ap-denylist-time <ap-denylist-time>
no...
```

Description

This command determines the time, in seconds, for which a client is manually blocked.

Parameter	Description
<ap-blacklist-time>/<ap-denylist-time>	The time, in seconds, that the client remains blocked.
no ap ap-blacklist-time	Removes the blacklist time configured using the <code>ap-blacklist-time</code> command and restores the default value of 3600 seconds.

Example

The following is an example of the `ap ap-blacklist-time/ap ap-denylist-time` command:

```
(host) [mynode] (config) #ap ap-blacklist-time 55/ap ap-denylist-time 55
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.7.1.1	The <code>no ap ap-blacklist-time</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on the Mobility Conductor.

ap arm client-match

```
ap arm client-match
  activate rules file-name <file-name>
  restore rules
```

Description

This command allows the managed device to use a newer set of ClientMatch rules without updating the entire operating system, reducing network downtime.

The ClientMatch rules that manage client associations are primarily based upon the client RF environment, and apply uniformly to all types of clients, regardless of device type or operating system. ArubaOS supports incremental updates to ClientMatch rules to support network devices running newer operating systems that may be incompatible with the existing ClientMatch client association rules. This feature allows the managed device to use a newer set of ClientMatch rules without updating the entire operating system, reducing network downtime.

Parameter	Description
<code>activate rules file-name <file-name></code>	File name of the client-match rules update package.
<code>restore rules</code>	Issue this command to remove an imported client-match rules update package and restore the default ClientMatch values.

Example

Use the WebUI or CLI to upload a custom update file of client -match rules to the /flash/config folder on Mobility Conductor. This feature is not available for stand-alone controller deployments.

```
(host)[mm](config)# copy tftp: <tftphost> <filename> flash: <destname>
(host)[mm](config)# copy ftp: <ftphost> <user> <password> flash: <destname>
(host)[mm](config)# copy scp: <scphost> <username> <password> flash:
<destname>
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

ap authorization-profile

```
ap authorization-profile {default | <profile-name>}
  ap-authorization-group <profile-name>
  clone {default | <source>}
  no
```

Description

The AP authorization-profile specifies which configuration should be assigned to a remote AP that has been provisioned but not yet authenticated at the remote site. By default, these yet-unauthorized APs are put into the temporary AP group **authorization-group** and assigned the predefined profile **NoAuthApGroup**. This configuration allows a user to connect to an unauthorized remote AP through a wired port and then enter a corporate username and password. Once a valid user has authorized the remote AP, the AP will be permanently marked as authorized on the network and will then download the configuration assigned to that AP by its permanent AP group.

Parameter	Description
ap authorization-profile <profile-name>	Name of this instance of the profile. 1-63 default
ap-authorization-group <profile-name>	Name of a configuration profile to be assigned to the group unauthorized remote APs.
clone {default <source>}	Copy data from another authorization profile. default
no	Delete command.

Example

The following command creates a new authorization profile with a non-default configuration for unauthorized remote APs:

```
(host) [mynode] (config) #ap authorization-profile default2
(host) [mynode] ((AP Authorization profile "default2") #authorization-group
NoAuthApGroup2
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

ap ble-configure

```
ap ble-configure
  {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
  cfg-ble-mac <cfg-ble-mac-addr>
  delete-slot slot <slot>
    interval <interval>
  generic-payload <generic-payload> slot <slot>
    interval <interval>
  major <major>
    minor <minor>
      UUID <uuid> interval
```

Description

This command configures beacon attributes like major, minor, and uuid on a managed device.

Syntax

Parameter	Description
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
cfg-ble-mac <cfg-ble-mac-addr>	The MAC address of the BLE device to be configured.
delete-slot slot <slot>	Delete beacon config of the specified slot number. For creating or deleting the beacon config, available range is [0,2]. For deleting beacons from all slots, 3 is reserved.
generic-payload <generic payload>	Custom Beacon payload. This is a variable length hex string.
major <major>	The IBeacon major number. 0-65535
minor <minor>	The IBeacon minor number. 0-65535
uuid <uuid>	The UUID of IBeacon. The UUID is always a fixed length hex string, for example: 4152554E-F99B-4A3B-86D0-947070693A78
interval	Beaconing interval in millisecond. 0-65535

Example

The following command sets beacon attributes:

```
[mynode] #ap ble-configure ap-name 325_2 cfg-ble-mac 84:eb:18:18:5e:f8 major  
1000 minor 2000
```

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

ap ble-init-action

ap ble-init-action ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ipv6 address>

Description

This command initiates BLE action for APs.

Parameter	Description
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ipv6 address>	IPv6 address of the AP.
add-log-level-str	This parameter will define BLE daemon log level as one of the following value: <ul style="list-style-type: none">ageoutamonapbat-https- jsonat-websocket-protobufAzure -IoT Hubbcnerrbcntl vbeaconbmreqcfgupdatecfgupdateerrdevmgmtenocanerrorfw-upgradefw-upgradeerrinfoiot-gwtagswarningzf
ap-sleep-duration-min	This parameter specifies AP sleep duration in minutes.
apb-clear-msg	This parameter clears incoming message buffer.
apb-power-reset	This parameter provides power-on reset for the on-board BLE radio.

Parameter	Description
apb-switch-bl	This parameter switches APB to bootloader image during image upgrades.
azure-clear-flash-provisioning	This parameter clears DPS provisioning information in the AP.
azure-dps-provisioning	This parameter forces AP to execute DPS provisioning.
azure-iothub-connect	This parameter forces AP to execute IoT Hub connecting.
clear-all-beacons	This parameter deletes all beacon data.
clear-all-log-mac-filters	This parameter clears all the BLE daemon log MAC filters.
clear-log-mac-filter	This parameter clears the BLE daemon log MAC filter.
input-filter-disable	This parameter disables input filter for storing devices in the BLE table.
input-filter-enable	This parameter enables input filter for storing devices in the BLE table.
iot-coex-disable	This parameter disables IoT coexistence for onboard IoT radio.
iot-coex-enable	This parameter enables IoT coexistence for onboard IoT radio.
log-level	BLE daemon log level specified as a number.
log-level-str	BLE daemon log levels specified as comma-separated values (without quotes). Possible values: 'info','warning','error','ageout','bmreq','fw-upgrade','fw-upgradeerr','cfgupdate','cfgupdateerr','beacon','bcntlv','bcnerr','apb','tags','zf','amon','iot_gw','at-https-json','at-websocket-protobuf'.
log-mac-filter	BLE daemon log MAC filter.
msg-select	Set bits to enable specific messages from APB to controller BLE Daemon - refer to BLE config CLI cmd.
ota-fw-upgrade	Over the Air firmware upgrade for onboard BLE.
remove-beacon-mac	Delete beacon with matching MAC address.
send-apb-update	Send APB info update to BLE Relay on controller.
send-update	Send IoT payload message to BMC immediately.
start-log	Enable BLE Daemon logging.

Parameter	Description
stop-log	Disable BLE Daemon logging.
zigbee permit-joining restart	Re-start zigbee initial permit joining duration.
all	Re-start all devices.
mac <mac-address>	Re-start specific devices.

Command History

Release	Modification
ArubaOS 8.7.0.0	The fololowing parameters are introduced: <ul style="list-style-type: none"> ■ input-filter-disable ■ input-filter-enable
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

apboot

```
apboot {all [global|local]|ap-group <ap-group> |ap-name <ap-name>|ip-addr <ipaddr>|ip6-addr <ip6addr>|wired-mac <macaddr>}
```

Description

This command reboots the specified APs.

You should not normally need to use this command as APs automatically reboot when you reprovision them. Use this command only when directed to do so by your Aruba representative.

Parameter	Description
all	Reboot all APs.
global	Reboot APs on all controllers.
local	Reboot only APs registered on this controller. This is the default.
ap-group	Reboot APs in a specified group.
ap-name	Reboot the AP with the specified name.
ip-addr	Reboot the AP at the specified IP address.
ip6-addr	Reboot the AP at the specified IPv6 address.
wired-mac	Reboot the AP at the specified MAC address.

Example

The following command reboots a specific AP:

```
(host) [mynode] (config)# apboot ap-name Building3-Lobby
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config mode on Mobility Conductor.

ap clarity-synthetic

```
ap clarity-synthetic {ap-name <ap-name> | wired-mac <wired-mac>}
  amsip-addr <amsip-addr> forward-mode
    gre test-id <test-id> | web-sockets test-id <test-id>
    mixed-mode band <a|g> | station-mode
  reset
```

Description

This command allows configuration of the Clarity-Synthetic feature. Clarity Synthetic enables the controller to select and convert a supported AP to client mode. The converted AP acts like a Wi-Fi client and starts synthetic data transaction within the network to monitor and detect the network health.

The Clarity Synthetic feature is supported on 200 Series, 210 Series, and 220 Series access points. This feature helps in detecting network health by using synthetic transaction from a Wi-Fi client. This feature converts the radios of a supported AP to change from AP mode to station mode.

Parameter	Description
<code>ap clarity-synthetic</code> {ap-name <ap-name> wired-mac <wired-mac>}	Specifies the name of the AP or the AP wired MAC address.
<code>amsip-addr <amsip-addr> forward-mode</code>	IP address of Clarity synthetic Server with the forward mode specified for test
<code>gre test-id <test-id> </code> <code>web-sockets test-id <test-id></code>	GRE mode of forwarding or the web sockets mode of forwarding with unique test id string
<code>mixed-mode band <a g> station-mode</code>	Specifies if AP operates in mixed mode (for either the a or g band) or in only station mode
<code>reset</code>	Resets the AP from Clarity Synthetic mode.

Example

The following command configures the IP address of the Clarity-Synthetic server (in the forward mode used for test) and specifies the GRE mode of forwarding for an AP working in the *a* band :

```
(host) [mynode] #ap clarity-synthetic wired-mac ac:a3:1e:d6:30:f0 amsip-addr
5.6.7.5 forward-mode gre test-id 5 mixed-mode band a
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Mobility Conductor	Base operating system.	Enable or Config mode on Mobility Conductor.

apconnect

```
apconnect {ap-name <name>|bssid <bssid>|ip-addr <ipaddr>}
```

Description

This command instructs a mesh point to disconnect from its current parent and connect to a new parent.

To maintain a mesh topology created using the **apconnect** command, Aruba suggests setting the mesh reselection-mode to **reselect-never**, otherwise the normal mesh reselection mechanisms could break up the selected topology.

Parameter	Description
ap-name <name>	Specify the name of the mesh point to be connected to a new parent.
bssid <bssid>	Specify the BSSID of the mesh point to be connected to a new parent.
ip-addr <ipaddr>	Specify the IP address of the mesh point to be connected to a new parent.

Example

The following command connects the mesh point “meshpoint1” to a new parent with the specified BSSID.

```
(host) [mynode] (config) #apconnect ap-name meshpoint1 parent-bssid  
00:12:6d:03:1c:f1
```

Related Commands

ap convert

```
ap convert
  active {all-aps|specified-aps}
  add {ap-group|ap-name}
  cancel
  clear-all
  delete {ap-group|ap-name}
  pre-validate {all-aps|specified-aps}
```

Description

This command is used to convert a Campus AP or a Remote AP to an Instant AP that is managed by Aruba Central. However, Aruba does not support this feature for Instant AP deployments that are managed through AirWave or local WebUI, and recommends using this command only in lab or test environments for such deployments.

- This feature is not supported on 320 Series AP models with 256 MB of SDRAM, manufactured between August 2015 and January 2016. These 320 Series AP models have a serial number that begins with DD (for example, DD0003824).
- The converted APs are limited to the highest supported version of the corresponding Instant APs. For example, if IAP-225 runs only up to Aruba Instant 8.6.0.0 version, the converted AP-225 will also support up to Aruba Instant 8.6.0.0 version.

Parameter	Description
<code>active {all-aps specified-aps}</code>	Convert active Campus AP or Remote AP to Instant APs that are managed by Aruba Central. NOTE: You can activate Instant AP conversion for all registered APs or APs specified by <code>ap convert ap-group</code> and/or <code>ap convert ap-name</code> commands.
<code>add {ap-group ap-name}</code>	Add AP group or AP name to list for AP conversion.
<code>cancel</code>	Cancel conversion. Any APs that are currently downloading the new image will continue to do so.
<code>clear-all</code>	Remove all AP groups and AP names from list for conversion.
<code>delete {ap-group ap-name}</code>	Delete AP group or AP name from list for conversion.

Parameter	Description
pre-validate {all-aps specified-aps}	Pre-validate the Campus AP or Remote AP to Aruba Activate or Central connection. NOTE: You can validate all registered APs or APs specified by <code>ap convert ap-group</code> and/or <code>ap convert ap-name</code> commands.

Example

The following example displays the options to convert all active Campus APs:

```
(host) [mynode] #ap convert active all-aps
activate           Convert CAP from activate.
local-flash       Convert CAP from MD local flash.
server            Convert CAP from local server.
```

The following example displays the options to convert specific Campus AP or Remote APs from local servers:

Before issuing the command, ensure that the **Read** permission is included for **Others** for the AP image files on the SCP server. This makes sure that the AP image file can be read during the conversion process.

```
(host) [mynode] #ap convert active specific-aps server
ftp               Download image from ftp server.
http              Download image from http server.
https             Download image from https server.
scp               Download image from scp server.
tftp              Download image from tftp server.
```

The following example validates Campus APs or Remote APs to Activate or Central connection:

```
(host) [mynode] (config) #ap convert pre-validate all-aps
WARNING: This command will validate AP to Activate/Central connection, which
include NTP time sync. Do you want to proceed with the operation? [y/n]: y
(host) [mynode] (config) #
```

ap-crash-transfer

ap-crash-transfer

Description

This command allows AP coredump files to be transferred to the controller flash memory if no dumpserver is configured.

The command `ap system-profile <profile> dump-server <server>` specifies a server to receive a core dump generated when an AP process crashes. If no dump server is configured, issue the `ap-crash-transfer` command to save dump files to the controller flash memory.

If you define a dump server and issue the `ap-crash-server` command, the dump server configuration takes precedence, and coredump files are sent to the dump server.

Example

```
(host)[mynode] (config) #ap-crash-transfer
```

Related Commands

Command	Description
show ap-crash-transfer	This command shows if AP coredump files can be transferred to controller flash memory if no dumpserver is configured.

ap debug dot 11r remove-key

```
ap debug dot 11r remove-key <mac>  
[ap-name <ap-name> | ip-addr <ip-addr>| ip6-addr <ip6-addr>]
```

Description

Use this command to remove an r1 key from an AP when the AP does not have a cached r1 key during Fast BSS Transition roaming.

Parameter	Description
<mac>	MAC address of the client.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.

Examples

You can use the following command to remove an r1 key from an AP when the AP does not have a cached r1 key during Fast BSS Transition roaming.

```
(host) [mynode] #ap debug dot11r remove-key <mac> ap-name <ap-name> | ip-  
addr <ip-addr>  
(host) [mynode] #ap debug dot11r remove-key 00:50:43:21:01:b8 ap-name  
MAcage-105-GL
```

Execute the following command to check if the r1 key is removed from the AP:

```
(host) [mynode] #show ap debug dot11r state ap-name MAcage-105-GL  
Stored R1 Keys  
-----  
Station MAC  Mobility Domain ID  Validity Duration  R1 Key  
-----
```

ap debug advanced-stats

```
ap debug advanced-stats {ap-name <ap-name>}|{ ip-addr <ip-addr>}|{ ip6-addr <ip-addr>}
```

Description

Issue this command under the supervision of Aruba technical support to enable the collection and display of advanced AP debugging information.

The additional information collected when advanced net80211 or radio statistics are enabled on an AP appears in the output of the [show ap debug radio-stats](#) command.

Parameter	Description
ap-name <ap-name>	Name of the AP for which you want to record advanced debugging information.
ip-addr <ip-addr>	IP address of the AP for which you want to record advanced debugging information.
ip6-addr <ip6-addr>	IPv6 address of the AP for which you want to record advanced debugging information.

ap debug client-trace stop

```
ap debug client-trace stop  
  {ap-name <ap-name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>}<mac>
```

Description

This command stops tracing management packets from a client MAC address. You must issue the command only under the guidance of Aruba technical support. This command is supported on 100 Series, 120 Series, and 130 Series access points only.

Parameter	Description
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IPv4 address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<mac>	MAC address of the client.

ap debug radio-diag-log

```
ap debug radio-diag-log {start | stop} {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>} grep <pattern> [size <num-bytes>]
```

Description

This command collects WLAN firmware diagnostic logs to facilitate firmware debugging. Configure the **dump-collection-profile** to use this command. When the **radio-diag-log** collection is stopped using `ap debug radio-diag-log stop` command, the log file is automatically transferred to the dump server that is configured in **dump-collection-profile**.

Parameter	Description
start	Starts logging the radio diagnostic messages.
grep	Stores only the filtered output. The pattern supports the same options as the AP shell's grep. NOTE: The grep pattern is mandatory.
stop	Stops logging the radio diagnostic messages.
size	Size of the radio diagnostic messages.

Example

The following command collects the grep output:

```
(host) [mynode] #ap debug radio-diag-log start ap-name <name> grep "-e WMI -e WAL"
```

Related Commands

ap debug radio-event-log

```
ap debug radio-event log [start|stop] [ap-name <name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>] radio <0|1> events [all|ani|hex|rcfind|rcupdate|rx|size|text|tx]>
```

Description

Start and stops packet log capture of radio events for debugging purposes, and sends a log file of the events to a dump server when logging stops.

Parameter	Description
start	Start Wi-Fi packet log capture.
ap-name <ap-name>	Name of the AP for which you want to capture packet log events.
radio 0 1	Include this parameter to start or stop packet log capture for the specified radio.
events	Classification the event type to capture, can be hex and multiple, default all. <ul style="list-style-type: none">■ all: Capture all of the following types of radio events■ ani : Adaptive Noise Immunity control events■ hex: Hex format of event tx=0x1 rx=0x2 rcfind=0x4 rcupdate=0x8 ani=0x10 text=0x20■ rcfind: Transmission (Tx) control event■ rcupdate: Transmission (Tx) rate update event■ rx: Received (Rx) status register event■ size: radio log size,range 1024-10485760 bytes(1KB-10MB), Default:3145728 bytes(3MB)■ text: Text record event■ tx: Transmission (Tx) control and Tx status register event
ip-addr <ip-addr>	IPv4 address of the AP for which you want to capture packet log events.
ip6-addr <ip6-addr>	IPv6 address of the for which you want to capture packet log events.
stop	Stop Wi-Fi packet log capture and send a log file of the events to a dump server.

Example

The following commands starts and stops a Wi-Fi radio event log:

```
(host) [mynode] #ap debug radio-event-log start ap-name 6c:f3:7f:c6:71:90  
radio 0 events all
```

```

ap debug radio-registers dump

```
ap debug radio-registers dump [[filename <filename> {all|interrupt|qcu |radio}]ap-name <name>|ip-addr <ip-addr>|ip6-addr <ip6-addr>]
```

Description

This command collects specified radio-register information for debugging purposes, dumps the registers into a local file, and will automatically transfer the file to the dump-server that is configured in ap-system-profile.

Parameter	Description
ap-name	Name of the access point.
filename	Name of file where information is collected.
all	All registers interrupted.
interrupt	Interrupt related registers.
qcu	Collect QCU information.
radio	Radio ID (0 or 1).
ip-addr	Collect radio register information for this specific AP radio.
ip6-addr	Collect radio register information for the AP assigned to this ipv6 address.

Example

The following command collects all radio registers from **myap1** into a file called **myradioregfile**:

```
(host) [mynode] #ap debug radio-registers dump ap-name myap1 filename myradioregfile all
```

Command History

ap debug stm-trace

```
ap debug stm-trace category  
[ip-addr <ip-addr> | loglevel | mac <mac>]
```

Description

This command enables / disables stm-trace categories.

Parameter	Description
category	The trace category to be enabled or disabled. <ul style="list-style-type: none">■ all - Traces all categories■ amon - Traces in the category of AMON■ auth - Traces in the category of authentication■ bss - Traces in the category of BSSIDs■ cluster - Traces in the category of cluster■ config - Traces in the category of configuration■ enet - Traces in the category of AP Enet port management■ gsm - Traces in the category of GSM■ radio - Traces in the category of radio■ sapm - Traces in the category of cluster■ sos - Traces in the category of SOS■ station - Traces in the category of stations■ syslog - Traces in the category of syslog■ system - Traces in the category of general system
ip-addr <ip-addr>	Trace events related to the AP IP address.
loglevel	The loglevel of the syslogs to be included in the trace. <ul style="list-style-type: none">■ alert - Trace all logs equal or higher than LOG_ALERT■ critical - Trace all logs equal or higher than LOG_CRIT■ debug - Trace all logs equal or higher than LOG_DEBUG■ emergency - Trace all logs equal or higher than LOG_EMERG■ error - Trace all logs equal or higher than LOG_ERR■ info - Trace all logs equal or higher than LOG_INFO■ notice - Trace all logs equal or higher than LOG_NOTICE■ warn - Trace all logs equal or higher than LOG_WARN
mac <mac>	Trace events related to the client MAC address.

Examples

You can use the following command to trace all events related to the IP address.

```
(host) [mynode] #ap debug stm-trace category all ip-addr <ip-addr>
```

```
(host) [mynode] #ap debug stm-trace category all 10.20.10.20
```

mac-list <mac_list>
wired-mac <wired_mac>
```

Description

This command is used to move the APs into deep-sleep mode.

Parameter	Description
ap-name	Name of an AP.
ip-addr	IP address of AP.
ip6-addr	IPv6 address of AP.
mac-list	Semicolon separated MAC address list. The maximum characters supported is 250.
wired-mac	The MAC address of an AP.

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

apdisconnect

```
apdisconnect {ap-name <name>|bssid <bssid>|ip-addr <ipaddr>}
```

Description

This command disconnects a mesh point from its parent.

Each mesh point learns about the mesh portal from its parent (a mesh node that is part of the path to the mesh portal). This command directs a mesh point to disassociate from its parent. The mesh point will attempt to associate with another neighboring mesh node, if available. The old parent is not eligible for re-association for 60 seconds after disconnection.

Syntax

Parameter	Description
ap-name	Specifies the name of the parent AP.
bssid	Specifies the BSSID of the parent AP.
ip-addr	Specifies the IP address of the parent AP.

Example

The following command disconnects a specific mesh point from its parent:

```
(host) [mynode] (config) #apdisconnect ap-name meshpoint1
```

Related Commands

Command	Description
apconnect	This command connects a mesh point to a new specified parent.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

ap deploy-profile

```
ap deploy-profile
  blacklist/denylist
  default-ap-group
  enable
  ip-range <start> <end>
  ipv6-range <start> <end>
  no
```

Description

This command applies the AP deployment policy to the default AP group, and/or to the list of AP MAC addresses included in the UAP blacklist/denylist table, and/or to the specified IP address range. The AP deployment policy redirects the applicable APs to the Instant discovery process, ensuring that the APs run only in controller-less mode.

Parameter	Description
blacklist/denylist	Enables the blacklist/denylist policy. Applies the AP deployment policy to the APs whose MAC addresses are included in the UAP blacklist/denylist table.
default-ap-group	Applies the AP deployment policy to the default AP group.
enable	Enables the AP deploy profile. The policies configured are enforced only if this is enabled.
ip-range	Applies the AP deployment policy to the specified IPv4 address range. You can define up to 128 IPv4 address ranges.
<start>	Starting IPv4 address of the range.
<end>	Ending IPv4 address of the range.
ipv6-range	Applies the AP deployment policy to the specified IPv6 address range. You can define up to 128 IPv6 address ranges.
<start>	Starting IPv6 address of the range.
<end>	Ending IPv6 address of the range.
no	Removes the AP deploy profile configuration.

Example

The following set of commands enable the AP deployment policy :

```
(host) [mynode] (config) #ap deploy-profile
(host) [mynode] (ap deploy-profile) #enable
```

The following command applies the AP deployment policy to an IPv4 address range with a starting IP address of 1.1.1.1 and ending IP address of 1.1.1.10:

```
(host) [mynode] (ap deploy-profile) #ip-range <1.1.1.1> <1.1.1.10>
```

The following command enables the blacklist/denylist policy in the AP deploy profile:

```
(host) [mynode] (ap deploy-profile) #blacklist/denylist
```

The following command removes the AP deployment policy configuration:

```
(host) [mynode] (config) #no ap deploy-profile
```

Related Commands

Command	Description
show ap deploy-profile	The <code>show ap deploy-profile</code> command displays the complete list of IP address ranges to which the AP deployment policy is applied.
uap-blacklist / uap-denylist	This command adds AP MAC addresses to the UAP blacklist/denylist database. When the blacklist/denylist policy is enabled in the AP deploy profile, it is applied to this blacklist/denylist database entries.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

ap enet-link-profile

```
ap enet-link-profile {default | <profile>}
  clone {default | <source>}
  dot3az
  dot3bz
  duplex {auto | full | half}
  no ...
  poe
  speed {10 | 100 | 1000 | 2500 | 5000 | auto}
```

Description

This command configures the duplex and speed of the Ethernet port on the AP. The configurable speed is dependent on the port type.

Parameter	Description
ap enet-link-profile <profile>	Name of this instance of the profile. The name must be 1-63 characters long.
clone <source>	Name of an existing Ethernet Link profile from which parameter values are copied.
dot3az	Enable support for the 803.az Energy Efficient Ethernet standard, which allows the APs to consume less power during periods of low data activity. If this feature is enabled for an AP group, any APs in the group that do not support 803.az will ignore this setting. disabled
dot3bz	Enable support for IEEE 802.3bz standard. Only 330 Series access points are compliant with this standard. enabled
duplex	The duplex mode of the Ethernet interface, either full, half, or auto-negotiated. full, half, auto auto
no	Negates any configured parameter.
poe	Enables PoE for APs that support PoE.
speed	The speed of the Ethernet interface, either 10 Mbps, 100 Mbps, 1000 Mbps (1 Gbps), or auto-negotiated. 10, 100, 1000, 2500, 5000, auto auto

Example

The following command configures the Ethernet link profile for full-duplex and 100 Mbps:

```
(host) [mynode] (config) #ap enet-link-profile enet
(host) [mynode] (AP Ethernet Link profile "enet") #duplex full
(host) [mynode] (AP Ethernet Link profile "enet") #speed 100
```

  ap-group <ap-group>
  ap-name <ap-name>
  ap31x-ap32x backup partition
  ip-addr <ip-addr>
  wired-mac <wired-mac>
```

Description

This command re-flashes the specified AP. Execute this command under the guidance of Aruba technical support.

Parameter	Description
all	Re-flash all APs.
global	Re-flash all APs on all managed devices.
local	Re-flash all APs registered on this device. This is the default setting.
ap-group	Re-flash all APs in this group.
ap-name	Re-flash AP with this name.
ap31x-ap32x backup partition	Upgrades the backup partition of Aruba 310 Series and 320 Series access points running ArubaOS 6.4.x or earlier versions to the ArubaOS version running on the Mobility Conductor.
ip-addr	Re-flash AP with this IP address.
wired-mac	Re-flash AP with this MAC address.

Example

The following command re-flashes an AP with an AP name *ap-corp-325*:

```
(host) [mynode] #apflash ap-name ap-corp-325
```

Command History

Release	Modification
ArubaOS 8.6.017, 8.7.1.9, 8.9.0.3	The ap31x-ap32x backup partition parameter was introduced.
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .

ap gap-db

```
ap gap-db
[reinit-
resync lms {lms-ip <lms-ip>}|{lms-ip6 <lms-ip6>} [{ap-name <ap-name>}|{wired-mac
<wired-mac>}]
```

Description

Resynchronize an AP status on a managed device and Mobility Conductor.

A managed device sends AP status messages about the APs terminating on that managed device to Mobility Conductor. In the event that an AP state appears to be different between Mobility Conductor and the managed device, this command will resynchronize the AP status information by allowing the managed device and Mobility Conductor to exchange a list of APs.

Parameter	Description
reinit-db	Re-initialize GAP DB.
resync	Trigger a re-sync.
lms	Specify the managed device to be synchronized.
lms-ip <lms-ip> lms-ip6 <lms-ip6>	Synchronize the status of all APs terminating on the specified Managed device. Specify either the IPv4 address or the IPv6 address of the managed device.
ap-name <ap-name>	Synchronize only the AP with the specified AP name.
wired-mac <wired-mac>	Synchronize only the AP with the specified MAC address.

Example

The following command triggers a resynchronization for an IPv4 address of the managed device.

```
(host)[mynode]#ap gap-db resync lms lms-ip 10.20.10.20
```

Command History

ap get-crash-dumps

```
ap get-crash-dumps
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
```

Description

This command allows AP crash dump files to be transferred to the controller flash memory on demand from the AP flash memory.

Parameter	Description
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.

Example

```
(host) [mynode] #ap get-crash-dumps ap-name ap535
```

Related Commands

ap general-profile

```
ap general-profile
  keepalive-timeout
  no
  periodic-sync
  stale-ap-ageout-time
  sync-interval
```

Description

This command configures the general profile of an AP.

Parameter	Description
keepalive-timeout	Specify the timeout interval in minutes for AP keepalive. 15-10080
no	Negates any previous configuration.
periodic-sync	Enables AP State periodic sync.
stale-ap-ageout-time	Specify the time interval in hours after which AP information is cleared automatically. 0-240 By default, this value is 0 and the auto clear function is disabled.
sync-interval <sync-interval>	Specifies AP State sync interval in minutes. 5-1440

Example

The following example enables the AP state periodic sync of an AP:

```
(host) [mynode] (config) #ap general-profile
(host) [mynode] (ap general-profile) #periodic-sync
```

Description

This command configures an AP group. AP groups are at the top of the configuration hierarchy. An AP group collects virtual AP definitions and configuration profiles, which are applied to APs in the group.

Parameter	Description
ap-group <profile-name>	Profile name that identifies the AP group. The name must be 1–63 characters long.

Parameter	Description
	NOTE: You cannot use quotes (") in the AP group name.
am-filter-profile <profile-name>	Configures the AM filter profile.
airslice-profile <name>	Configures the Air Slice profile.
airslice-visibility record-limit <record-count>	Defines the maximum number of records stored for clients.
ap-multizone-profile <profile-name>	Configures the AP MultiZone profile.
ap-system-profile <profile-name>	Configures AP administrative operations, such as logging levels. See ap system-profile on page 354 .
authorization-profile <profile-name>	Restrictive group for unauthorized AP.
clone <source>	Name of an existing AP group from which profile names are copied.
dot11-60GHz-radio-profile <profile-name>	Configures 802.11 60 GHz radio profile. See rf dot11-60GHz-radio-profile on page 1226 .
dot11-6GHz-radio-profile <profile-name>	Configures 802.11 6 GHz radio profile.
dot11a-radio-profile <profile-name>	Configures 802.11a radio settings and load balancing for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 1196 .
dot11a-secondary-radio-profile <profile-name>	Configures 802.11a secondary radio settings and load balancing for the AP group; contains the ARM profile.
dot11a-traffic-mgmt-profile <profile-name>	Configures bandwidth allocation. See wlan traffic-management-profile on page 4204 .

Parameter	Description
<pre>dot11g-radio-profile <profile-name></pre>	<p>Configures 802.11g radio settings and load balancing for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 1196.</p>
<pre>dot11g-traffic-mgmt-profile <profile-name></pre>	<p>Configures bandwidth allocation. See wlan traffic-management-profile on page 4204.</p>
<pre>enet-usb-port-profile default NoAuthWiredPort shutdown <profile-name></pre>	<p>Allows connection of certain devices that use a USB connection as an Ethernet port. This parameter configures the USB port to function as a wired port (downlink), which is governed by AP wired-port profiles.</p> <p>shutdown</p> <p>NOTE: This parameter is not applicable when a USB modem that is connected to an IAP or Remote AP functions as an uplink.</p>
<pre>enet0-port-profile <profile-name></pre>	<p>Configures the duplex and speed of the Ethernet interface 0 on the AP. For information on how these profiles are defined, see ap wired-port-profile on page 415.</p>
<pre>enet1-port-profile <profile-name></pre>	<p>Configures the duplex and speed of the Ethernet interface 1 on the AP. For information on how these profiles are defined, see ap wired-port-profile on page 415.</p>
<pre>enet2-port-profile <profile-name></pre>	<p>Configures the duplex and speed of an Ethernet interface 2 on the AP. These profiles are defined using the command ap wired-port-profile on page 415.</p>
<pre>enet3-port-profile <profile-name></pre>	<p>Configures the duplex and speed of an Ethernet interface 3 on the AP. These profiles are defined using the command ap wired-port-profile on page 415.</p>
<pre>enet4-port-profile <profile-name></pre>	<p>Configures the duplex and speed of an Ethernet 4 interface on the AP. For information on how these profiles are defined, see ap wired-port-profile on page 415.</p>

Parameter	Description
event-thresholds-profile <profile-name>	Configures Received Signal Strength Indication (RSSI) metrics. See rf event-thresholds-profile on page 1245 .
gps-service-profile <profile-name>	Configures GPS service profile.
ids-profile <profile-name>	Configures Aruba's IDS. See ids profile on page 706 .
iot radio-profile <profile-name>	Apply IoT radio profile.
mesh-accesslist-profile	Configures the mesh access list profile.
mesh-cluster-profile <profile-name>	Configures the mesh cluster profile for mesh nodes that are members of the AP group. There is a "default" mesh cluster profile; however, it is not applied until you provision the mesh node. See ap mesh-cluster-profile on page 276 .
priority <1-16>	Configures the priority of the mesh cluster profile. If more than two mesh cluster profiles are configured, mesh points use this number to identify primary and backup profile(s). The lower the number, the higher the priority. 1-16 1
mesh-radio-profile <profile-name>	Configures the 802.11g and 802.11a radio settings for mesh nodes that are members of the AP group. See ap mesh-ht-ssid-profile on page 279 . Commands to configure mesh for outdoor APs require the Outdoor Mesh license.
no	Negates any configured parameter.
provisioning profile <profile-name>	Configures the provisioning profile.

Parameter	Description
regulatory-domain-profile <profile-name>	Configures the country code and valid channels. See ap regulatory-domain-profile on page 341 .
rf-optimization-profile <profile-name>	Configures coverage hole and interference detection. See rf optimization-profile on page 1252 .
virtual-ap <profile-name>	One or more profiles, each of which configures a specified WLAN. See wlan virtual-ap on page 4210 .
wifi-uplink-profile <wifi-uplink-profile>	Configures a specified Wi-Fi uplink. See ap wifi-uplink-profile on page 407 .
usb-profile <profile-name>	USB profile applied to the AP group.
virtual-ap <profile-name>	One or more profiles, each of which configures a specified WLAN. See wlan virtual-ap on page 4210 .
zigbee service-profile <profile-name>	Apply zigbee related profile.

Example

The following command configures a virtual AP profile to the “default” AP group:

```
(host)[mynode](config) #ap-group test1
(host)[mynode] (AP group "test1") #virtual-ap corpnet
```

The following command configures a Wi-Fi uplink profile to the “default” AP group:

```
(host)[mynode](config)# ap-group wfu-test
Warning: WiFi uplink profile will not take effect until an AP is
reprovisioned
(host)[mynode] (AP group "wfu-test")# wifi-uplink-profile test-uplink
priority 1
```

Related Commands

ap image-preload

```
ap image-preload
activate all-aps|specific-aps
add {ap-group <ap-group> | ap-name <ap-name>}
cancel
clear-all
delete {ap-group <ap-group> | ap-name <ap-name>}
[partition <part-num>
[max-downloads <max-downloads>]
```

Description

Configure APs to preload a new software image from a managed device before it starts actively running the new image.

The AP image preload feature minimizes the downtime required for a Mobility Conductor upgrade by allowing the APs to download the new images before the Mobility Conductor actually starts running the new version.

This feature allows you to select the maximum number of APs that are allowed to preload the new software image at any one time, thereby reducing the possibility that the Mobility Conductor may get overloaded or that network traffic may be impacted by all APs on the Mobility Conductor attempting to download a new image at once.

APs can continue normal operation while they are downloading their new software version. When the download completes, the AP sends a message to the Mobility Conductor, informing it that the AP has either successfully downloaded the new software version, or that the preload has failed for some reason. If the download fails, the AP will retry the download after a brief waiting period.

You can allow every AP on a managed device to preload a new software version, or also create a custom list of AP groups or individual APs that can use this feature. If a new AP associates to the managed device while the AP image download feature is active, the managed device will check the name and group of that AP to see if it appears in the preload list. If an AP is on the list, (and does not already have the specified image in its Flash memory) that AP will start preloading its image.

Once a software version has been downloaded by an AP, another version cannot be downloaded until the AP reboots.

Parameter	Description
activate	Activate this feature, allowing APs in the preload list to start downloading their new image from the managed device.
all-aps	All APs will be allowed to pre-download the image.

Parameter	Description
<code>specific-aps</code>	Only APs in the preload list will be allowed to preload the image.
<code>add</code>	Add individual APs or AP groups to the list of APs allowed to preload the image.
<code>ap-group <group></code>	Add a group of APs to the preload list.
<code>ap-name <name></code>	Add an individual AP to the preload list.
<code>cancel</code>	Cancel the AP preload and clear the preload list. Any APs downloading a new image at the time this command is issued will continue to download the file.
<code>clear-all</code>	Clear all APs from the preload list.
<code>delete</code>	Delete an individual AP or AP group from the preload list. This command may be issued before or after preloading is activated. If it is executed after preloading has already been activated, any APs downloading a new image at the time this command is issued will continue to download the file. APs that are still waiting to preload will be removed from the preload list.
<code>ap-group <group></code>	Remove the specified group of APs from the preload list
<code>ap-name <name></code>	Remove an individual AP from the preload list
<code>partition <partition-num></code>	Specify the partition from which the APs should download their images. By default, the APs will preload images from the default boot partition of the managed device.
<code>max-downloads <max-downloads></code>	Specify the maximum number of APs that can simultaneously download their image from the managed device. The default value is ten APs.

Example

The following command enables the image preload feature and adds the APs in the AP groups corp1 and corp2 to the preload list.

```
(host) [mynode] (config) #ap image-preload activate specific-aps
(host) [mynode] (config) #add ap-group corp1
(host) [mynode] (config) #add ap-group corp2
```

ap-lacp-striping-ip

```
ap-lacp-striping-ip
  aplacp-enable
  no
  striping-ip <ip-addr> lms <LMS>
```

Description

Define an AP LACP LMS map information profile that maps a GRE striping IP address to an existing LMS-IP address.

The **AP LACP LMS map information** profile is a local profile that maps a LMS IP address (defined in the AP system profile) to a GRE striping IP address. If 220 Series or 270 Series access points fail over to a standby or backup controller, the AP LACP LMS map information profile on the new controller defines the IP address that the APs use to terminate 802.11.g radio tunnels on the new controller. This feature allows 220 Series, 270 Series, and 320 Series access points to continue to support link aggregation to a backup controller in the event of a controller failure even if the backup controller is in a different L3 network.

If your topology includes a backup controller you must define GRE striping IP settings in the active and the backup controller.

Parameter	Description
ap-lacp-striping-ip	Configures the AP LACP LMS map information.
aplacp-enable	Enables LACP IP striping. This feature is disabled by default.
no ...	Negate any setting or return a configured parameter to its default value.
striping-ip <ip-addr>	Specify an IPv4 address for the 802.11g radio of the controller to allow LACP-enabled switches to send traffic for the two controller radios on different links. Recommended value for this parameter is lms <ip-addr>+1 .
lms <LMS>	Enter the LMS IP address currently defined in the device's AP system profile to map the existing LMS IP to the GRE striping IP address.

Examples

The following commands enable LACP IP striping on the Mobility Conductor:

```
(host)[node] (config) #ap system-profile LACP
```

```
(host)[node] (AP system-profile "LACP") #lms-ip 192.0.2.1
(host)[node] (AP system-profile "LACP") #bkup-lms-ip 192.0.77.1
(host)[node] (AP system-profile "LACP") #exit
(host)[node] (config) #ap-lacp-striping-ip
(host)[node] (AP LACP LMS map information) #striping-ip 192.0.2.2 lms
192.0.2.1
(host)[node] (AP LACP LMS map information) #aplacp-enable
```

The following commands enable LACP IP striping on an L2-connected High Availability (HA) standby or HA+VRRP controller:

```
(bkup-host)[node] (config) #ap-lacp-striping-ip
(bkup-host)[node] (config) (AP LACP LMS map information) #striping-ip
192.0.2.16 lms 192.0.2.1
(bkup-host) [node] (config)(AP LACP LMS map information) #aplacp-enable
```

The following commands enable LACP IP striping on L3-connected High Availability (HA) standby controllers, or HA controllers in dual HA mode, where each dual-mode controller acts as standby for the APs served by the other dual-mode controller:

```
(bkup-host)[node] (config) #ap-lacp-striping-ip
(bkup-host)[node] (config) (AP LACP LMS map information) #striping-ip
10.1.1.14 lms 192.0.2.1
(bkup-host)[node] (config) (AP LACP LMS map information) #striping-ip
192.0.2.2 lms 192.0.2.1
(bkup-host) [node] (config)(AP LACP LMS map information) #aplacp-enable
```

If you are using High Availability between L3-connected or dual-mode controllers, you must configure **two** different striping IPs (one for each subnet) to ensure that both controllers will have striping IPs mapped to the corresponding LMS IP address.

Important Points to Remember

- In the upstream direction when the AP transmits GRE frames to the Mobility Conductor the bonding driver must be in active-active mode and not in the default active-standby mode to allow link aggregation.
- If an AP's uplink access switch ports are configured in static port-channel mode, then the AP will set the Ethernet bonding mode to static port-channel (xor mode) only if **gre-striping-ip** is configured. If **gre-striping-ip** is not configured, then the AP goes back to **active-standby** mode. In this scenario, the AP may go down depending on the behavior of the upstream switch.
- If an AP's uplink access switch ports are configured in dynamic LACP mode, the AP detects LACP-PDUs and automatically sets the Ethernet bonding mode to LACP. If **gre-striping-ip** is

not configured, then the AP's Ethernet bonding mode will continue to be in LACP mode, but the AP will send GRE traffic only through one Ethernet port.

- In 320 Series and 330 Series access points, if AP uplink packet capture is taken, the downstream traffic will have sequence number in GRE header. Wireshark Aruba wlan decoder will not be able to decode these packets correctly since it looks for known Aruba GRE tunnel IDs.
- Ensure that the **gre-striping-ip** is unique and not used by any other host on the subnet.
- LACP support is limited to a use case where Enet 0 and Enet 1 ports of the AP are connected to a switch, and LACP is enabled on the two corresponding switch ports.
- The port priority is not applicable to the AP as both ports need to be used. This value is always set to the maximum numerical priority (0xFF), which is the lowest priority.
- The system priority is not configurable. It is set to the maximum numerical value (0xFFFF), which is the lowest priority. This leaves control of the aggregate to the upstream switch.
- The timeout value is not configurable.
- The key is not configurable and the default key value is 1.
- LACP cannot be enabled if wired AP functionality is enabled on the second port. You cannot enable LACP if the Enet 1 port is shutdown.

Troubleshooting Link Aggregation

The following show commands in the CLI can be used to troubleshoot Link Aggregation on 220 Series , 270 Series, 320 Series and 330 Series access points:

- `show ap debug lacp ap-name <ap-name>`—Using this command, you can view if LACP is active on an AP. It displays the number of GRE packets sent and received on the two Ethernet ports. Using this command with verbose option on 320 Series and 330 Series access points displays packet re-ordering statistics of each wlan client.
- `show ap database`—The output of this command includes an **LACP Striping** flags to indicate of the AP is configured with a LACP striping IP address,
- `show datapath tunnel`—Using this command on 220 Series/270 Series access points, you can verify if the 2.4GHz tunnels are anchored on the **gre-striping-ip** (The GRE IDs for these tunnels are in a range between 0x8300 and 0x83F0) . On 320 Series and 330 Series access points, use the verbose option to verify that 5 Ghz tunnels have striping IP set in the column **StripIP** (The GRE IDs for these tunnels are in a range between 0x8200 and 0x82F0).
- `show datapath station`—On 320 Series and 330 Series access points, using this command displays the LACP sequence number sent in the GRE header of the last packet to the client. This information is displayed under **Seq** column.
- `show ap remote debug anul-sta-entries`—On 320 Series and 330 Series access points, using this command displays LAG enabled/disabled per station and data drops due to LAG packet reordering.
- `show datapath user`—Using this command, you can verify if the **gre-striping-ip** has an entry with the 'L' (local) flag

- `show datapath route-cache`—Using this command, you can verify if the **gre-striping-ip** has an entry with the LC MAC.

Related Commands

The following show commands display information about the settings defined in the AP LACP LMS map information profile:

Command	Description
show ap-lacp-striping-ip	Displays all settings defined in AP LACP LMS map information profile.
show ap database	The output of this command displays an s flag to indicate that the AP is enabled with a striping IP address.
show ap debug lacp	The output of this command displays the striping IP address of the AP, as defined in the AP LACP LMS map information profile.

All platforms	Base operating system.	Config mode on Mobility Conductor.

ap-leds

ap-leds

```
{all | ap-group <ap-group> | ap-name <ap-name> | ip-addr <ip address> | wired-mac  
<mac address>}
```

Description

This command allows you to make the LEDs on a defined set of APs either blink or display in the currently configured LED operating mode. Note that if the LED operating mode defined in the AP's system profile is set to "off", then the `normal` parameter in the `ap-leds` command will disable the LEDs. If the LED operating mode in the AP system profile is set to "normal" then the `normal` parameter in this command will allow the LEDs light as usual.

Parameter	Description
<code>all</code>	Controls the LED behavior for all APs.
<code>global</code>	Selects all APs on all controllers. <ul style="list-style-type: none">▪ blink: Make LEDs blink for identification.▪ fault-disable: Disable the fault LED if fault is detected. This is applicable for APs with one LED only.▪ fault-enable: Enable the fault LED if fault is detected. This is applicable for APs with one LED only.▪ normal: Restore LEDs to their normal behavior.
<code>local</code>	Selects all APs registered on this controller.
<code>ap-group <ap-group></code>	Controls the LED behavior for APs in the specified group.
<code>ap-name <ap-name></code>	Controls the LED behavior for the AP with the specified name.
<code>ip-addr <ip-addr></code>	Controls the LED behavior for the AP with the specified IP address.
<code>wired-mac <mac-addr></code>	Controls the LED behavior for the AP with the specified MAC address.

Example

The following command causes all local APs to blink their LEDs for identification purposes:

```
(host) [mynode] (config) #ap-leds
```

ap lldp med-network-policy-profile

```
ap lldp med-network-policy-profile {default | <profile-name>}
  application-type
  guest-voice
  guest-voice-signaling
  softphone-voice
  streaming-video
  video-conferencing
  video-signaling
  voice
  voice-signaling
  clone {default | <source>}
  dscp <dscp>
  l2-priority <l2-priority>
  no ...
  tagged
  vlan <vlan>
```

Description

Define an LLDP MED network policy profile that defines DSCP values and L2 priority levels for a voice or video application.

LLDP-MED (media endpoint devices) is an extension to LLDP that supports interoperability between VoIP devices and other networking clients. LLDP-MED network policy discovery lets endpoints and network devices advertise their VLAN IDs (for example, voice VLAN), priority levels, and DSCP values. ArubaOS supports a maximum of eight LLDP -MED Network Policy profiles.

Creating an LLDP MED network policy profile does not apply the configuration to any AP or AP interface or interface group. To apply the LLDP-MED network policy profile, you must associate it to an LLDP profile, then apply that LLDP profile to an AP wired port profile.

Parameter	Description
ap lldp med-network-policy-profile <profile-name>	Configures an AP LLDP-MED Network Policy Profile. Default
application-type	Specifies the type of application that this profile manages.
guest-voice	Use this application type if the AP services a separate voice network for guest users and visitors.
guest-voice-signaling	Use this application type if the AP is part of a network that requires a different policy for guest voice signaling than for guest voice media. Do not use this application type if both the same network policies apply to both guest voice and guest voice signaling traffic.

Parameter	Description
<code>softphone-voice</code>	Use this application type if the AP supports voice services using soft phone software applications on devices such as PCs or laptops.
<code>streaming-video</code>	Use this application type if the AP supports broadcast or multicast video or other streaming video services that require specific network policy treatment. This application type is not recommended for video applications that rely on TCP with buffering.
<code>video-conferencing</code>	Use this application type if the AP supports video conferencing equipment that provides real-time, interactive video and audio services.
<code>video-signaling</code>	Use this application type if the AP is part of a network that requires a different policy for video signaling than for the video media. Do not use this application type if both the same network policies apply to both video and video signaling traffic.
<code>voice</code>	Use this application type if the AP services IP telephones and other appliances that support interactive voice services. This is the default application type.
<code>voice-signaling</code>	Use this application type if the AP is part of a network that requires a different policy for voice signaling than for the voice media. Do not use this application type if both the same network policies apply to both voice and voice signaling traffic.
<code>clone {default <source>}</code>	Makes a copy of an existing profile by specifying that profile name.
<code>dscp <dscp></code>	Selects a DSCP priority value for the specified application type by specifying a value from 0-63, where 0 is the lowest priority level and 63 is the highest priority. 0-63 0
<code>l2-priority <L2-priority></code>	Select a 802.1p priority level for the specified application type, by specifying a value from 0-7, where 0 is the lowest priority level and 7 is the highest priority. 0-7 0
<code>no</code>	Negates any setting or return a configured parameter to its default value.

Parameter	Description
tagged	Specifies if the policy applies to a to a VLAN that is tagged with a VLAN ID or untagged. The default value is untagged. When an LLDP-MED network policy is defined for use with an untagged VLAN, then the L2 priority field is ignored and only the DSCP value is used. untagged
vlan <vlan>	Specifies a VLAN by VLAN ID (0-4094) or VLAN name. 0

Example

The following commands create a LLDP MED network policy profile for streaming video applications and marks streaming video as high-priority traffic.

```
(host) [mynode] (config) #ap lldp med-network-policy-profile vid-stream
(host) [mynode] (AP LLDP-MED Network Policy Profile "vid-stream") #dscp 48
(host) [mynode] (AP LLDP-MED Network Policy Profile "vid-stream") #l2-
priority 6
(host) [mynode] (AP LLDP-MED Network Policy Profile "vid-stream") #tagged
(host) [mynode] (AP LLDP-MED Network Policy Profile "vid-stream") #vlan 10
```

Next, the LLDP MED network policy profile is assigned to an LLDP profile, and the LLDP profile is associated with an AP wired-port profile.

```
(host) [mynode] (config) #ap lldp profile video1
(host) [mynode] (AP LLDP Profile "video1") #ap lldp-med-network-policy-
profile vid-stream
(host) [mynode] (AP LLDP Profile "video1") #
(host) [mynode] (config) #ap wired-port-profile corp2
(host) [mynode] (AP wired port profile "corp2") #lldp-profile video1
```

```

Description

Define an LLDP profile that specifies the TLV elements to be sent in LLDP PDUs.

LLDP is a Layer-2 protocol that allows network devices to advertise their identity and capabilities on a LAN. Wired interfaces on Aruba APs support LLDP by periodically transmitting LLDP PDUs consisting of TLV elements. Use this command to specify the TLV that should be sent by the AP interface associated with the LLDP profile.

Parameter	Description
ap lldp profile <profile-name>	Configures an AP LLDP profile. default
clone <profile>	Make a copy of an existing LLDP profile. default
dot1-tlvs	Specify the 802.1 TLV that the AP will send in LLDP PDUs. By default, the AP will send every 802.1 TLV.
port-vlan	Transmit the LLDP 802.1 port VLAN TLV. If the native VLAN is configured on the port, the port-vlan TLV will send that value, otherwise it will send a value of 0.
vlan-name	Transmit the LLDP 802.1 VLAN name TLV. The AP sends a value of "Unknown" for VLAN 0, or "VLAN <number>" for non-zero VLAN numbers.
dot3-tlvs	Specify the 802.3 TLV that the AP will send in LLDP PDUs. By default, the AP will send every 802.3 TLV.
link-aggregation	Transmit the 802.3 link aggregation TLV to indicate that link aggregation is not supported.

Parameter	Description
mac	Transmit the 802.3 MAC or PHY Configuration or Status TLV to indicate the duplex and bit rate capacity, and current duplex and bit rate settings of the AP interface.
mfs	Transmit the 802.3 Maximum Frame Size TLV to show the maximum frame size capability of the AP.
power	Transmit the 802.3 Power via media dependent interface (MDI) TLV to show the power support capabilities of the AP interface. This parameter is supported by the RAP-3WNP and 130 Series only.
lldp-med-network-policy-profile <profile>	Specify the LLDP MED Network Policy profile to be associated with this LLDP profile.
lldp-med-tlvs	Specify the LLDP-MED TLV that the AP will send in LLDP PDUs. By default, the AP will not send any LLDP-MED TLV.
capabilities	Transmit the LLDP-MED capabilities TLV. The AP will automatically send this TLV if any other LLDP-MED TLV is enabled.
inventory	Transmit the LLDP-MED inventory TLV. An AP cannot send this TLV unless it also sends the LLDP-MED capabilities TLV.
network-policy	Transmit the LLDP-MED network-policy TLV. An AP cannot send this TLV unless it also sends the LLDP-MED capabilities TLV.
optional-tlvs	Specify the optional TLV that the AP will send in LLDP PDUs.
capabilities	Transmit the system capabilities TLV to indicate which capabilities are supported by the AP.
management-address	Transmit a TLV that indicates the management IP address of the AP, in either IPv4 or IPv6 format.
port-description	Transmit a TLV that gives a description of the wired port of an AP in an alphanumeric format.
system-description	Transmit a TLV that describes the model number and software version of the AP.
system-name	Transmit a TLV that sends the AP name or wired MAC address.
receive	Issue this command to enable LLDP PDU reception. This parameter is enabled by default.

Parameter	Description
transmit	Issue this command to enable LLDP PDU transmission. This parameter is enabled by default.
transmit-hold <transmit-hold>	Enter a value from 1-100. This value is multiplied by the transmit interval to determine the number of seconds to cache learned LLDP information before that information is cleared. If the transmit-hold value is at the default value of 4, and the transmit interval is at its default value of 30 seconds, then learned LLDP information will be cached for 4 x 30 seconds, or 120 seconds. 1-100 4
transmit-interval <transmit-interval>	The interval between LLDP TLV transmission seconds. The supported range is 1-3600 seconds and the default value is 30 seconds. 1-3600 30

Example

The following command configures an LLDP profile, allows the AP interface to send the port-vlan and vlan-name TLV.

```
(host) [mynode] (config)#ap lldp profile 8021TLVs
(host) [mynode] (AP LLDP Profile "8021TLVs") #dot1-tlvs port-vlan
(host) [mynode] (AP LLDP Profile "8021TLVs") #dot1-tlvs vlan-name
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

```

ap mesh-accesslist-profile <name>
  ap-name <ap-name>
  type [allow | deny]
  clone <source>
  no

```

Description

This command configures a mesh access list profile. Mesh access list profile defines the list of APs each AP is allowed to discover in a mesh topology.

Parameter	Description
ap mesh-accesslist-profile <name>	Defines the name of the mesh access list profile.
ap-name <ap-name>	APs that are either allowed or denied to be discovered.
type	Allows or Denies APs to be discovered.
allow	Allows the APs in the list to be discovered. All other APs not in the list will be denied.
deny	APs in the list will not be discovered. All other APs not in the list will be allowed.
clone <source>	Copies data from a different mesh access list profile.
no	Deletes the profile.

The mesh access list profile is associated to an AP group or an AP using the following commands:

```

(host) [mynode] (config) #ap-group default
(host) [mynode] (AP group "default") #mesh-accesslist-profile Guest
(host) [mynode] (config) #ap-name AP-505
(host) [mynode] (AP name "AP-505") #mesh-accesslist-profile Guest

```

Example

The following commands configure a mesh access list profile:

```

(host) [mynode] (config) #ap mesh-accesslist-profile Guest
(host) [mynode] (Mesh Accesslist profile "Guest") #ap-name lab-1
(host) [mynode] (Mesh Accesslist profile "Guest") #ap-name AP-303
(host) [mynode] (Mesh Accesslist profile "Guest") #ap-name AP-3034
(host) [mynode] (Mesh Accesslist profile "Guest") #type allow

```

Command History

ap mesh-cluster-profile

```
ap mesh-cluster-profile <profile-name>
  clone <source>
  cluster <cluster>
  no
  opmode {opensystem|wpa2-psk-aes}
  rf-band {a|g|all}
  rf-split5G-band-range { first | full | lower |upper }
  wpa-hexkey <wpa-hexkey>
  wpa-passphrase <wpa-passphrase>
```

Description

Mesh cluster profiles are specific to mesh nodes (APs configured for mesh) and provide the framework of the mesh network. You must define and configure the mesh cluster profile before configuring an AP to operate as a mesh node.

You can configure multiple mesh cluster profiles to be used within a mesh cluster. You must configure different priority levels for each mesh cluster profile. See [ap-group](#) or [ap-name](#) for more information about priorities.

Cluster profiles, including the default profile, are not applied until you provision your APs for mesh.

Parameter	Description
ap mesh-cluster-profile <profile-name>	Configures a mesh cluster profile. Give a name to the mesh cluster profile. The name must be 1–63 characters long.
clone <source>	Copies parameter values from an existing mesh cluster profile.
cluster <cluster>	Indicates the mesh cluster name. The name can have a maximum of 32 characters and is used as the MSSID for the mesh cluster. When you first create a new mesh cluster profile, the profile uses the default cluster name “Aruba-mesh”. Use the <code>cluster</code> parameter to define a new, unique MSSID before you assign APs or AP groups to the mesh cluster profile. If you want a mesh cluster to use WPA2-PSK-AES encryption, <i>do not use spaces in the mesh cluster name</i> , as this may cause errors in mesh points associated with that mesh cluster.
no	Negates any configured parameter.
opmode	Configures one of the following data encryption types: <ul style="list-style-type: none">■ opensystem: No encryption.■ wpa2-psk-aes: WPA2 with AES encryption using a pre-shared key.

Parameter	Description
	<p>Best practices are to select wpa2-psk-aes and use the <code>wpa-passphrase</code> parameter to select a passphrase. Keep the passphrase in a safe place.</p> <p>opensystem, wpa2-psk-aes</p> <p>opensystem</p>
<code>rf-band</code>	<p>Configures the RF band in which multiband mesh nodes must operate:</p> <ul style="list-style-type: none"> ■ a: 802.11a ■ g: 802.11g ■ all: all bands. Mesh feature will be enabled on both a and g bands. <p>Best practices are to use 802.11a radios for mesh deployments.</p> <p>a</p>
<code>rf-split5G-band-range</code>	<p>This command configures the 5 GHz radio used for the mesh link. This parameter takes effect only when split 5 GHz or dual 5 GHz radio is enabled on the AP. Reboot the AP must for the configuration to take effect.</p>
<code>first</code>	<p>Configures the functioning 5 GHz radio as the mesh link.</p>
<code>full</code>	<p>Configures both the sub bands of the 5 GHz radio as the mesh link. The radio assignment however depends on factors such as hopcount to the mesh portal, availability of neighboring mesh APs, and preferred uplink radio setting of the mesh profile. This is the default setting.</p>
<code>lower</code>	<p>Configures the lower 5 GHz radio as the mesh link.</p>
<code>upper</code>	<p>Configures the upper 5 GHz radio as the mesh link.</p>
<code>wpa-hexkey <wpa-hexkey></code>	<p>Configures a WPA PSK.</p>
<code>wpa-passphrase <wpa-passphrase></code>	<p>Sets the WPA password that generates the PSK.</p>

Example

The following command configures a mesh cluster profile named `cluster1`, for the mesh cluster headquarters:

```
(host) [mynode] (config) #ap mesh-cluster-profile cluster1
(host) [mynode] (Mesh Cluster profile "cluster1")cluster headquarters
```

Description

The mesh HT SSID profile defines settings unique to 802.11n-capable, high-throughput APs. If none of the APs in your mesh deployment are 802.11n-capable APs, you do not need to configure a HT SSID profile.

If you modify a currently provisioned and running high-throughput SSID profile, your changes take effect immediately. You do not reboot the Mobility Conductor or the AP.

Parameter	Description
ap mesh-ht-ssid-profile <profile-name>	Configures a Mesh HT SSID profile. Enter the name of an existing mesh high-throughput SSID profile to modify that profile, or enter a new name or create a new mesh HT profile. The mesh HT profile can have a maximum of 32 characters.

Parameter	Description
	To view existing HT SSID radio profiles, use the command <code>show ap mesh-radio-profile</code> . default
40MHz-enable	Enable or disable the use of 40 MHz channels. enabled
80MHz-enable	Enable or disable the use of 80 MHz channels. enabled
ba-amsdu-enable	Enable or Disable Receive AMSDU in BA negotiation. enabled
clone <source>	Copy configuration information from a source profile into the currently selected profile.
high-efficiency-enable	Enables high-efficiency (802.11ax) features on this SSID.
high-throughput-enable	Enable or disable HT (802.11n) features on this SSID. enabled
ldpc	If enabled, the AP will advertise Low-density Parity Check (LDPC) support. LDPC improves data transmission over radio channels with high levels of background noise. enabled
legacy-stations	Allow or disallow associations from legacy (non-HT) stations. By default, this parameter is enabled (legacy stations are allowed). enabled
max-rx-a-mpdu-size	Maximum size of a received aggregate MPDU, in bytes. 8191, 16383, 32767, 65535
max-tx-a-mpdu-size <max-tx-a-mpdu-size>	Maximum size of a transmitted aggregate MPDU, in bytes. 1576-65535
max-tx-a-msdu-count-be <max-tx-a-msdu-count-be>	Maximum number of MSDUs in a TX A-MSDU on best-effort AC. TX-AMSDU disabled if 0. 0-15 2
max-tx-a-msdu-count-bk <max-tx-a-msdu-count-bk>	Maximum number of MSDUs in a TX A-MSDU on background AC. TX-AMSDU disabled if 0.

Parameter	Description
	0-15 2
max-tx-a-msdu-count-vi <max-tx-a-msdu-count-vi>	Maximum number of MSDUs in a TX A-MSDU on video AC. TX-AMSDU disabled if 0. 0-15 2
max-tx-a-msdu-count-vo <max-tx-a-msdu-count-vo>	Maximum number of MSDUs in a TX A-MSDU on voice AC. TX-AMSDU disabled if 0. 0-15 0
max-vht-mpdu-size	Maximum size of a VHT MPDU. 3895, 7991, 11454 11454
min-mpdu-start-spacing	Minimum time between the start of adjacent MPDUs within an aggregate MPDU, in microseconds. 0, 0.25, 0.5, 1, 2, 4, 8, 16 0
mpdu-agg	Enable or disable MPDU aggregation. HT mesh APs are able to send aggregated MPDUs, which allow an AP to receive a single block acknowledgment instead of multiple ACK signals. This option, which is enabled by default, reduces network traffic overhead by effectively eliminating the need to initiate a new transfer for every MPDU. enabled
no	Delete command.
short-guard-intvl-20Mhz	Enable or disable use of short (400 ns) guard interval for 130 Series APs in 20 MHz mode. A guard interval is a period of time between transmissions that allows reflections from the previous data transmission to settle before an AP transmits data again. An AP identifies any signal content received inside this interval as unwanted inter-symbol interference, and rejects that data. The 802.11n standard specifies two guard intervals: 400 ns (short) and 800 ns (long). Enabling a short guard interval can decrease network overhead by reducing unnecessary idle time on each AP. Some outdoor deployments, may, however require a longer guard interval. If the short guard interval does not allow enough time for reflections to settle in your mesh deployment, inter-symbol interference values may increase and degrade throughput.

Parameter	Description
	enabled
short-guard-intvl-40Mhz	<p>Enable or disable use of short (400 ns) guard interval in 40 MHz mode.</p> <p>A guard interval is a period of time between transmissions that allows reflections from the previous data transmission to settle before an AP transmits data again. An AP identifies any signal content received inside this interval as unwanted inter-symbol interference, and rejects that data.</p> <p>The 802.11n standard specifies two guard intervals: 400 ns (short) and 800 ns (long). If the short guard interval does not allow enough time for reflections to settle in your mesh deployment, inter-symbol interference values may increase and degrade throughput.</p> <p>enabled</p>
stbc-rx-streams	<p>Controls the maximum number of spatial streams usable for STBC reception. 0 disables STBC reception, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on the 130 Series, 170 Series and AP-105 only. The configured value will be adjusted based on AP capabilities.)</p> <p>0-1 1</p>
stbc-tx-streams	<p>Controls the maximum number of spatial streams usable for STBC transmission. 0 disables STBC transmission, 1 uses STBC for MCS 0-7. Higher MCS values are not supported. (Supported on 170 Series, 130 Series and AP-105 only. The configured value will be adjusted based on AP capabilities.)</p>

Parameter	Description
	0-1 1
supported-mcs-set <supported-mcs-set>	A list of Modulation Coding Scheme (MCS) values or ranges of values to be supported on this SSID. The MCS you choose determines the channel width (20 MHz vs. 40 MHz) and the number of spatial streams used by the mesh node. The default value is 0-31—16-23 are supported on 130 Series/RAP-15x/802.11ac APs only; 24-31 are supported on 320 Series/330 Series only. To specify a smaller range of values, enter a hyphen between the lower and upper values. To specify a series of different values, separate each value with a comma. 0-31 0-31
temporal-diversity	Shows if temporal diversity has been enabled or disabled. When this feature is enabled and the client is not responding to 802.11 packets, the AP will launch two hardware retries; if the hardware retries are not successful then it attempts software retries. disabled
very-high-throughput-enable	Shows if very-high-throughput (802.11ac) features are enabled or disabled. enabled
vht-supported-mcs-map <supported-mcs-set>	Comma-separated list of max supported MCS for spatial streams 1 through 4. Valid values for max MCS are 7, 8, 9, and - (if spatial stream is not supported). Max MCS of a spatial stream cannot be higher than the MCS of the previous stream. If an MCS is not valid for a particular combination of bandwidth and number of spatial streams, it will not be used for Tx and Rx. 9,9,9,9
vht-txbf-explicit-enable	Enable or Disable use of VHT Explicit Transmit Beamforming. enabled

Example

The following command configures a mesh HT SSID profile named “HT1” and sets some non-default settings for MPDU aggregation:

```
(host) [mynode] (config) #ap mesh-ht-ssid-profile HT1
```

```
(host) [mynode] (Mesh High-throughput SSID profile "HT1") #max-rx-a-mpdu-size 32767
(host) [mynode] (Mesh High-throughput SSID profile "HT1") #max-tx-a-mpdu-size 32767
(host) [mynode] (Mesh High-throughput SSID profile "HT1") #min-mpdu-start-spacing .25
```

Description

Mesh radio profiles are specific to mesh nodes (APs configured for mesh) and determine the RF or channel used by mesh nodes to establish mesh links and the path to the mesh portal. You can configure multiple radio profiles; however, you select and deploy only one radio profile per mesh cluster.

Radio profiles, including the “default” profile, are not active until you provision your APs for mesh. If you modify a currently provisioned and running radio profile, your changes take place immediately. You do not reboot the Mobility Conductor or the AP.

Parameter	Description
ap mesh-radio-profile <profile>	Configures a Mesh Radio profile. Give a name to this instance of the profile. The name must be 1–63 characters long.

Parameter	Description
	default
a-tx rates	<p>Indicates the transmit rates for the 802.11a radio. The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.</p> <p>6, 9, 12, 18, 24, 36, 48, 54</p>
allowed-vlans	<p>Specifies a list of VLAN IDs that can be used by a mesh link on APs associated with this mesh radio profile</p>
<vlan-list>	<p>A comma-separated list of VLAN IDs. You can also specify a range of VLAN IDs using a dash (for example, 1-4095)</p>
children <children>	<p>Indicates the maximum number of children a mesh node can accept.</p> <p>1-64 64</p>

Parameter	Description
clone <source>	<p>Name of an existing mesh radio profile from which parameter values are copied.</p> <p>default</p>
eapol-rate-opt	<p>Use a more conservative rate for more reliable delivery of EAPOL frames.</p> <p>disabled</p>
g-tx rates	<p>Indicates the transmit rates for the 802.11b or 802.11g radio.</p> <p>The AP attempts to use the highest transmission rate to establish a mesh link. If a rate is unavailable, the AP goes through the list and uses the next highest rate.</p> <p>1, 2, 5, 6, 9, 11, 12, 18, 24, 36, 48, 54</p>
heartbeat-threshold <heartbeat-threshold>	<p>Indicates the maximum number of heartbeat messages that can be lost between neighboring mesh nodes.</p> <p>1-255</p> <p>30</p>

Parameter	Description
<pre>hop-count <hop-count></pre>	<p>Indicates the maximum hop count from the mesh portal.</p> <p>1-32</p> <p>8</p>
<pre>link-threshold <link-threshold></pre>	<p>Indicates the minimal RSSI value. If the RSSI value is below this threshold, the link may be considered a sub-threshold link. A sub-threshold link is a link whose average RSSI value falls below the configured threshold. If this occurs, the mesh node may try to find a better link on the same channel and cluster (only neighbors on the same channel are considered). The supported threshold is hardware dependent, with a practical range of 10-90.</p> <p>12</p>
<pre>max-retries <max-retries></pre>	<p>Maximum number of times a mesh node can re-send a packet.</p> <p>0-15</p> <p>4</p>

Parameter	Description
<pre>mesh-ht-ssid-profile <profile-name></pre>	<p>HT SSID Profile for the mesh feature.</p> <p>default</p>
<pre>mesh-mcast-opt</pre>	<p>Enables or disables scanning of all active stations currently associated to a mesh point to select the lowest transmission rate based on the slowest connected mesh child. When enabled, this setting dynamically adjusts the multicast rate to that of the slowest connected mesh child. Multicast frames are not sent if there are no mesh children. Best practices are to use the default value.</p> <p>enabled</p>
<pre>mesh-mobility</pre>	<p>Enables fast roaming on a mobility mesh point based on low RSSI or missed beacon frames.</p> <p>disabled</p>

Parameter	Description
<code>mesh-survivability</code>	<p>Allows mesh points and portals to become active even if the Mobility Conductor cannot be reached by bridging LAN traffic. This is a beta feature that is disabled by default; it should not be enabled unless you are instructed to do so by Aruba technical support.</p> <p>distributed-tree-rssi</p>
<code>metric-algorithm</code>	<p>Specifies the algorithm used by a mesh node to select its parent.</p> <p>distributed-tree-rssi</p>
<code>mobility-beacon-miss</code> <mobility-beacon-miss>	<p>Triggers fast roaming on a mobility mesh point when number of consecutive missed beacon frames reaches the threshold value.</p> <p>10-25</p> <p>16</p>
<code>mobility-rssi</code> <mobility-rssi>	<p>Triggers fast roaming on a mobility mesh point when RSSI of the parent is lower than the threshold value.</p>

Parameter	Description
	10-50 15
best-link-rssi	Selects the parent with the strongest RSSI, regardless of the number of children a potential parent has.
distributed-tree-rssi	Selects the parent based on link-RSSI and node cost based on the number of children. This option evenly distributes the mesh points over high quality uplinks. Low quality uplinks are selected as a last resort.
mpv <mpv>	This parameter is experimental and reserved for future use. 0-4094 0
no	Negates any configured parameter.
optimize-scan-interval	Configures the time period to perform mesh scanning. Range: 1 to 100 hours Default: 24 hours

Parameter	Description
prefer-uplink-radio	Configures the preferred 5 GHz radio for mesh links. Mesh link neighbors identified in this radio band will be prioritized over other neighbors identified in other radio band. This parameter will take effect only when dual 5 GHz or split 5 GHz radio is enabled on the AP and when rf-split5G-band-range is set to full.
2g	Configures 2.4G radio band as preferred uplink.
5g	Configures 5G radio band as preferred uplink.
5g-lower	Configures 5G radio band as preferred uplink.
5g-upper	Configures 5G radio band as preferred uplink .
6GHz versions)	<p data-bbox="708 1541 1052 1566">ArubaOS 8.9.0.0 or later</p> <p data-bbox="1214 1514 1393 1623">Configures 6 GHz radio band as preferred uplink .</p> <p data-bbox="1214 1654 1393 1764">NOTE: This sub-parameter is applicable to Wi-Fi 6E APs</p>

Parameter	Description
	only.
none	Does not specify any radio band as preferred uplink .
reselection-mode	Specifies the method used to find a better mesh link. Best practices are to use the default value startup-subthreshold. start-subthreshold
reselect-anytime	Starting from ArubaOS 8.8.0.0, mesh points using the reselect-anytime reselection mode will perform periodically triggered optimize scanning. This time period is defined using the optimize-scan-interval parameter. If no better parent is found, the mesh point returns to its original parent.

Parameter	Description
	<p>This initial scan first evaluates more distant mesh points before evaluating closer mesh points, and incurs a dropout of 5-8 seconds for each mesh point.</p> <p>Prior to ArubaOS 8.8.0.0, Mesh points using the reselect-anytime reselection mode perform a single topology readjustment scan within 9 minutes of startup and 4 minutes after a link is formed. If no better parent is found, the mesh point returns to its original parent.</p> <p>This initial scan evaluates more distant mesh points before closer mesh points, and incurs a dropout of 5-8 seconds for each mesh point.</p>

Parameter	Description
	After the initial startup scan is completed, connected mesh nodes evaluate mesh links every 30 seconds. If a mesh node finds a better uplink, the mesh node connects to the new parent to create an improved path to the mesh portal.
reselect-never	Connected mesh nodes do not evaluate other mesh links to create an improved path to the mesh portal.

Parameter	Description
startup-subthreshold	<p>Mesh points using the startup-subthreshold reselection mode perform a single topology readjustment scan within 9 minutes of startup and 4 minutes after a link is formed. If no better parent is found, the mesh point returns to its original parent. This initial startup scan evaluates more distant mesh points before closer mesh points, and incurs a dropout of 5–8 seconds for each mesh point. After that time, each mesh node evaluates alternative links if the existing uplink falls below the configured threshold level (the link becomes a sub-threshold link). Best practices are to use the default startup-subthreshold value.</p>

Parameter	Description
	<p>If a mesh point using the startup-subthreshold mode reselects a more distant parent because its original, closer parent falls below the acceptable threshold, then as long as that mesh point is connected to that more distant parent, it will seek to reselect a parent at the earlier distance (or less) with good link quality.</p> <p>For example, if a mesh point disconnects from a mesh parent 2 hops away and subsequently reconnects to a mesh parent 3 hops away, then the mesh point will continue to seek a connection to a mesh parent with both an acceptable link quality and a distance of two hops or less, even if the more distant parent also has an acceptable link quality.</p>

Parameter	Description
subthreshold-only	<p>Starting from ArubaOS 8.8.0.0, the connected mesh nodes evaluate alternative links only if the signal strength of the existing uplink is lesser than the signal strength of link threshold.</p> <p>Prior to ArubaOS 8.8.0.0, Connected mesh nodes evaluate alternative links only if the existing uplink becomes a sub-threshold link.</p>

Parameter	Description
	<p>Starting with ArubaOS 3.4.1, if a mesh point using the subthreshold-only mode reselects a more distant parent because its original, closer parent falls below the acceptable threshold, then as long as that mesh point is connected to that more distant parent, it will seek to reselect a parent at the earlier distance (or less) with good link quality. For example, if a mesh point disconnects from a mesh parent 2 hops away and subsequently reconnects to a mesh parent 3 hops away, then the mesh point will continue to seek a connection to a mesh parent with both an acceptable link quality and a distance of two hops or less, even if the more distant parent also has an acceptable link quality.</p>

Parameter	Description
<code>rts-threshold</code> <code><rts-threshold></code>	Defines the packet size sent by mesh nodes. Mesh nodes transmitting frames larger than this threshold must issue RTS and wait for other mesh nodes to respond with CTS to begin transmission. This helps prevent mid-air collisions. 256-2346 2333

Example

The following example creates a mesh radio profile named "radio2" and associates a mesh HT profile named meshHT1.

```
(host) [mynode] (config) #ap mesh-radio-profile radio2
(host) [mynode] (Mesh Radio profile "radio2") #mesh-ht-ssid-profile meshHT1
```

The following example configures fast roaming on a mobility mesh point.

```
(host) [mynode] (config) #ap mesh-radio-profile mesh_radio_roaming
(host) [mynode] (Mesh Radio profile "mesh_radio_roaming") #mesh mobility
(host) [mynode] (Mesh Radio profile "mesh_radio_roaming") #mobility-rssi 20
(host) [mynode] (Mesh Radio profile "mesh_radio_roaming") #mobility-beacon-miss 10
```

The following example configures 6 GHz radio band on the mesh node for AP-635 access point (ArubaOS 8.9.0.0 or later versions).

```
(host) [mynode] (config) #ap mesh-radio-profile default
(host) [mynode] (Mesh Radio profile "default") #prefer-uplink-radio 6GHz
```

Related Commands

Command	Description
<code>show ap mesh-radio-profile</code>	To view the settings of a specific mesh radio profile.

Command History

Release	Modification
ArubaOS 8.9.0.0	The 6GHz sub-parameter under prefer-uplink-radio parameter was introduced.
ArubaOS 8.8.0.0	The following changes were introduced: <ul style="list-style-type: none"> ■ The optimize-scan-interval parameter was introduced. ■ The functionality of reselect-any-time and subthreshold-only reselection-modes were changed. ■ The mesh-mobility, mobility-beacon-miss <mobility-beacon-miss>, and mobility-rssi <mobility-rssi> parameters were introduced.
ArubaOS 8.7.0.0	The prefer-uplink-radio parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

ap modem

```

ap modem
  upgrade <all-aps>|<specific-aps>
  activate
    max-downloads <max-downloads>
  server
    ftp {username <username>|<hostname>}|
    http {username <username>|<hostname>}|
    https {username <username>|<hostname>}|
    scp {username <username>|<hostname>}|
    tftp <hostname>

```

Description

This command upgrades the firmware version of Aruba AP USB LTE modem from the managed device. The managed device first downloads the modem firmware, and then the Remote AP downloads the firmware from the managed device.

Parameter	Description
<code>upgrade <all-aps> <specific-aps></code>	Upgrades modem firmware for all registered APs or the APs specified by ap-group or ap-name.
<code>activate</code>	Downloads modem firmware from activate.
<code>max-downloads <max-downloads></code>	Specify how many applications can download modem firmware at the same time. The default value is 10.
<code>server</code>	Downloads modem firmware from the local server.
<code>ftp {username <username> <hostname>}</code>	Downloads modem firmware from the FTP server.
<code>http {username <username> <hostname>}</code>	Downloads modem firmware from the HTTP server.
<code>https {username <username> <hostname>}</code>	Downloads modem firmware from the HTTPS server.
<code>scp {username <username> <hostname>}</code>	Downloads modem firmware from the SCP server.
<code>tftp <hostname></code>	Downloads modem firmware from the TFTP server.

Example

The following example upgrades modem firmware from the TFTP server for all registered APs.

```
(host) [mynode] #ap modem upgrade all-aps tftp 144.37.254.3 ArubaOS_90xx_
lte_fw_v20_77807
```

ap modem-upgrade

```
ap modem-upgrade
    {activate | add <ap-group|ap-name>| clear-specific-list | delete <ap-
group|ap-name>| reset}
```

Description

This command configures the firmware upgrade of Aruba USB LTE modem, and decides which AP gets upgraded when you issue the `ap modem upgrade <specific-aps>` command. You can add or remove specific AP name or AP group, as well as remove all the AP names and AP groups from the list for modem firmware upgrade. You can also reset the entire firmware upgrade before initiating a new upgrade.

Parameter	Description
<code>activate {disable enable}</code>	Disable or enable automatical upgrade from activate.
<code>add [ap-group <ap-group> ap-name <ap-name>]</code>	Adds AP group or AP name to the list for modem firmware upgrade.
<code>clear-specific-list</code>	Removes all AP groups and AP names from list for modem upgrade.
<code>delete [ap-group <ap-group> ap-name <ap-name>]</code>	Deletes AP group or AP name from list for modem upgrade.
<code>reset</code>	Resets the existing modem firmware upgrade.

Parameter	Description
	<p>This parameter resets the entire upgrade process before a new upgrade is initiated. Hence, you must issue the <code>ap modem-upgrade reset</code> command between two firmware upgrade processes.</p> <p>NOTE: This parameter does not interrupt or cancel the existing firmware download on APs.</p>

Example

The following example removes the AP name from the list for modem firmware upgrade.

```
(host) [mynode] #ap modem-upgrade delete ap-name test
```

ap multizone-profile

```
ap multizone-profile <profile-name>
  clone <source>
  datazone <zone>
    controller-ip <ipv4>
    controller-ipv6 <ipv6>
    description <description>
    max-nodes <num_nodes>
    max-vaps <num_nodes>
  multizone-enable
  no
  primaryzone
    max-nodes <num_nodes>
    max-vaps <num_nodes>
```

Description

MultiZone feature allows AP to terminate to multiple managed devices that reside in different zones. A zone is a collection of managed devices under a single administration domain. The zone can have a single managed device or a cluster. This command allows you to create an AP MultiZone profile, set the data zone index, and controller-ip.

Parameter	Description
<profile-name>	Name of the profile.
clone	Copy data from one AP MultiZone profile to another.
datazone	Data zone Index [1 - 4].
controller-ip <ipv4>	The IPv4 address of the managed device to be configured on one of the data zones.
controller-ipv6 <ipv6>	The IPv6 address of the managed device to be configured on one of the data zones.
description <description>	The description of the data zone. The range of the string is 1-32.
max-nodes <num_nodes>	(Optional) The maximum number of managed devices allowed for the data zone. The range should be between 1 - 11, as the primary zone must have at least one managed device. Default value is 1.
max-vaps <num_vaps>	(Optional) The maximum number of ESSIDs allowed for the data zone. The range should be between 1 - 16. Default value is 3.

Parameter	Description
<code>multizone-enable</code>	If enabled, AP enters MultiZone mode. Default value is disabled.
<code>no</code>	Delete command.
<code>primaryzone</code>	This parameter is used to configure the primary zone.
<code>max-nodes <num_nodes></code>	(Optional) The maximum number of managed devices allowed for the primary zone. The range should be between 1 - 11, as the primary zone must have at least one managed device. Default value is 1.
<code>max-vaps <num_vaps></code>	(Optional) The maximum number of ESSIDs allowed for the primary zone. The range should be between 1 - 16. Default value is 3.

Example

The following command enables AP MultiZone:

```
(host) [mynode] (config) #ap multizone-profile <default> multizone-enable
```

The following command configures IPv6 address of the managed device and sets maximum number of managed devices and ESSIDs on the data zone:

```
(host) [mynode] (config) (ap multizone-profile <default>)# datazone 1
controller-ipv6 2001:1001::201 max-nodes 2 max-vaps 3
```

Command History

Release	Modification
ArubaOS 8.4.0.0	<p>The following sub-parameters were introduced in the <code>datazone</code> parameter:</p> <ul style="list-style-type: none"> ■ <code>controller-ipv6 <ipv6></code> ■ <code>description <description></code> ■ <code>max-nodes <num_nodes></code> ■ <code>max-vaps <num_vaps></code> <p>The following sub-parameters were introduced in the <code>primaryzone</code> parameter:</p> <ul style="list-style-type: none"> ■ <code>max-nodes <num_nodes></code> ■ <code>max-vaps <num_vaps></code>

Release	Modification
ArubaOS 8.1.0.0	The <code>primaryzone</code> parameter was added.
ArubaOS 8.0.1.0	The <code>num-nodes</code> sub-parameter was added.
ArubaOS 8.0.0.0	Command introduced.

apmove

```
apmove
  all
  ap-group <ap-group>
  ap-mac <ap-mac>
```

Description

When HA is enabled, use this command to move an AP or group of APs to their managed devices. This command should be used when it is necessary to move a single AP, all APs in an ap-group, or all APs to switchover to their standby managed device without an actual failure of the active managed device. For example, this allows the network admin to manually move one or more APs to their managed device and perform a planned upgrade or maintenance on the active managed device.

Parameter	Description
all	Move all APs.
ap-group <ap-group>	Move all APs belonging to the specified AP group.
ap-mac <ap-mac>	Move all APs belonging to the MAC of the specified AP.
target-v4	Target managed device IPv4 address.
target-v6	Target managed device IPv6 address.

```

Description

This command configures a specific AP. Profiles that are applied to an AP group can be overridden on a per-AP name basis, and virtual APs can be added or excluded on a per-AP name basis. If a particular profile is overridden for an AP, all parameters from the overriding profile are used. There is no merging of individual parameters between the AP and the AP group to which the AP belongs.

Parameter	Description
ap-name <profile-name>	<p>Configures an AP name. Give a name that identifies the AP. By default, the name of an AP can either be its Ethernet MAC address, or if the AP has been previously provisioned with an earlier version of ArubaOS, a name in the format <building>.<floor>.<location>. The name must be 1-63 characters long.</p> <p>NOTE: You cannot use quotes (") in the AP name.</p>
airslice-profile <name>	Configures an Air Slice profile.
am-filter-profile <profile-name>	Configures AM filter profile.
am-multizone-profile <profile-name>	Configures AP MultiZone profile.
ap-system-profile <profile-name>	Configures AP administrative operations, such as logging levels. See ap system-profile on page 354 .
authorization-profile <profile-name>	Restrictive group for unauthorized AP.
clone <source>	Name of an existing AP name from which profile names are copied.
dot11-60GHz-radio-profile <profile-name>	Configures 802.11 60GHz radio settings for the AP group; contains the ARM profile.
dot11-6GHz-radio-profile <profile-name>	Configures 802.11 6GHz radio settings for the AP group; contains the ARM profile.
dot11a-radio-profile <profile-name>	Configures 802.11a radio settings for the AP group; contains the ARM profile. See rf dot11a-radio-profile on page 1196 .
dot11a-secondary-radio-profile <profile-name>	Configures 802.11a secondary radio settings for the AP group; contains the ARM profile.
dot11a-traffic-mgmt-profile <profile-name>	Configures bandwidth allocation. See wlan traffic-management-profile on page 4204 .

Parameter	Description
dot11g-radio-profile <profile-name>	Configures 802.11g radio settings for the AP group; contains the ARM profile. See rf dot11g-radio-profile on page 1228 .
dot11g-traffic-mgmt-profile <profile-name>	Configures bandwidth allocation. See wlan traffic-management-profile on page 4204 .
enet0-profile <profile-name>	Configures the duplex and speed of the Ethernet 0 interface on the AP. See ap enet-link-profile on page 241 .
enet1-profile <profile-name>	Configures the duplex and speed of the Ethernet 1 interface on the AP. See ap enet-link-profile on page 241 .
enet2-profile <profile-name>	Configures the duplex and speed of the Ethernet 2 interface on the AP. See ap enet-link-profile on page 241 .
enet3-profile <profile-name>	Configures the duplex and speed of the Ethernet 3 interface on the AP. See ap enet-link-profile on page 241 .
enet4-profile <profile-name>	Configures the duplex and speed of the Ethernet 4 interface on the AP. See ap enet-link-profile on page 241 .
event-thresholds-profile <profile-name>	Configures Received Signal Strength Indication (RSSI) metrics. See rf event-thresholds-profile on page 1245 .
exclude-mesh-cluster-profile-ap <profile-name>	Excludes the specified mesh cluster profile from this AP. The Secure Enterprise Mesh license must be installed.
exclude-virtual-ap <profile-name>	Excludes the specified virtual AP profiles from this AP.
exclude-wifi-uplink-profile <profile-name>	Excludes the specified Wi-Fi uplink profiles from this AP.
gps-service-profile <profile-name>	Configures GPS service profile.

Parameter	Description
ids-profile <profile-name>	Configures Aruba's IDS. See ids profile on page 706 .
iot <profile-name>	Applies iot related profile.
mesh-accesslist-profile	Configures the mesh access list profile.
mesh-cluster-profile <profile-name>	Configures the mesh cluster profile for the AP (mesh node). There is a "default" mesh cluster profile; however, it is not applied until you provision the mesh node. See ap mesh-cluster-profile on page 276 . The Secure Enterprise Mesh license must be installed.
priority <priority>	Configures the priority of the mesh cluster profile. If more than two mesh cluster profiles are configured, mesh points use this number to identify primary and backup profile(s). The supported range of values is 1–16. The lower the number, the higher the priority. 1
mesh-radio-profile <profile-name>	Configures the 802.11g and 802.11a radio settings for the AP (mesh node). See ap mesh-ht-ssid-profile on page 279 . The Secure Enterprise Mesh license must be installed.
no	Negates any configured parameter.
regulatory-domain-profile <profile-name>	Configures the country code and valid channels. See ap regulatory-domain-profile on page 341 .
rf-optimization-profile <profile-name>	Configures load balancing and coverage hole and interference detection. See rf optimization-profile on page 1252 .
usb-profile <profile-name>	Configures USB profile.
virtual-ap <profile-name>	One or more profiles, each of which configures a specified WLAN. See wlan virtual-ap on page 4210 .

Parameter	Description
wifi-uplink-profile <profile-name>	Configures Wi-Fi uplink profile.
zigbee service-profile <profile-name>	Apply zigbee related profile.

Example

The following command excludes a virtual AP profile from a specific AP:

```
(host) [mynode] (config) #ap-name 00:0b:86:c0:cf:d8
(host) [mynode] (AP name "00:0b:86:c0:cf:d") #exclude-virtual-ap corpnet
```

```

Description

These commands manage WiFi packet capture (PCAP) on Aruba APs. The WiFi packets are encapsulated in a UDP header and sent to a client running a packet analyzer like Wildpacket's Airopeek, Omnipeek, or Wireshark.

These commands direct an AP to send Wi-Fi packet captures to a client packet analyzer utility such as Airmagnet, Wireshark and so on, on a remote client.

Before using these commands, you need to start the packet analyzer utility on the client and open a capture window for the port from which you are capturing packets. The packet analyzer cannot be used to control the flow or type of packets sent from APs.

The packet analyzer processes all packets. However, you can apply display filters on the capture window to control the number and type of packets being displayed. In the capture window, the time stamp displayed corresponds to the time that the packet is received by the client and is not synchronized with the time on the AP.

Filter specification (used in ap packet-capture interactive) supports the following:

■ type (beacon/rts/cts/data/ack/ctrl/mgmt/all)

■ sta (mac address)

■ ssa (mac address)

■ sta (mac address)

■ ssa (mac address)

■ dir (tods, fromds)

■ retry (1, 0)

■ frag (1, 0)

■ wep (1, 0)

Filter spec examples:

(type eq beacon) or ((sta eq 000000010203) and (dir eq tods))

(type == data) && ((sta = 000000010203) || (sta == 000000010203))

(type != beacon)

(wep nq 1)

(type eq all)

Syntax

Parameter	Description
clear	Clears the packet capture session.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<pcap-id>	ID of the PCAP session.
radio <0-2>	ID of the radio sending the packets
close-port <port>	(CPsec Campus APs and Remote APs only) Close or disallow access to this UDP port on the AP for packet capture purposes.
interactive	Start an interactive packet capture session between an AP and a client running a packet analyzer.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<filter-spec>	Packet Capture filter specification. See Usage Guidelines for details.
<target-ip>	IP address of the client running the packet analyzer.
<target-port>	UDP port number on the client station where the captured packets are sent.
radio <0-2>	ID of the radio sending the packets
channel <channel>	(Optional or Applicable only in AM mode) Number of a radio channel to tune into to capture packets.
open-port <port>	(CPsec Campus APs and Remote APs only) Enable or allow access to this UDP port on the AP for packet capture purposes.

Parameter	Description
pause	Pause a packet capture session.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<pcap-id>	ID of the PCAP session.
raw-start	Stream packets from the driver to a client running the packet analyzer.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<target-ip>	IP address of the client running the packet analyzer.
<target-port>	UDP port number on the client station where the captured packets are sent.
<format>	Packet capture format. Enter any number between 0 and 6 to select the one of the following formats: <ul style="list-style-type: none"> ▪ 0 - pcap ▪ 1 - peek ▪ 2 - airmagnet ▪ 3 - pcap+radio header ▪ 4 - ppi ▪ 5 - peek with 11n/11ac header ▪ 6 - radiotap
radio <0-2>	ID of the radio sending the packets
channel <channel>	(Optional or Applicable only in AM mode) Number of a radio channel to tune into to capture packets.
maxlen <maxlen>	(Optional) Limit the length of 802.11 frames to include in the capture to a specified maximum.
resume	Resume a packet capture session.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<pcap-id>	ID of the PCAP session.

Parameter	Description
radio <0-2>	ID of the radio sending the packets.
stop	Stop a packet capture session.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<pcap-id>	ID of the PCAP session.
radio <0-2>	ID of the radio sending the packets
wired-start	Start a wired ethernet packet stream to an external viewer.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<target-ip>	IP address of the client running the packet analyzer.
<target-port>	UDP port number on the client station where the captured packets are sent.
wired-stop	Halt a wired ethernet packet stream currently being sent to an external viewer.
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.
<target-ip>	IP address of the client running the packet analyzer.
<target-port>	UDP port number on the client station where the captured packets are sent.

Examples

The following command starts a raw packet capture session for the AP **ly115** on radio **0**, and sends the packets to the client at **10.64.102.4** on port **5000**.

```
(host) [mynode] (config) #ap packet-capture raw-start ap-name ly115
10.64.102.4 5000 0 radio 0
Packet capture has started for pcap-id:1
```

The following commands start an interactive packet capture session for the AP **ap1**.

```
#ap packet-capture open-port 5555
#ap packet-capture interactive ap-name ap1 "type eq all" 192.168.0.3 5555
radio 0
```

The output of the command in the example below displays packet capture session statistics for the AP **ap1**. In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual CLI, it will appear in a single, long table.

```
#show ap packet-capture status ap-name ap1

Packet Capture Sessions at ap1, IP 10.3.44.167
-----
pcap-id  filter      type      intf      channel max-pkts
-----  -
1        type eq all  interactive 6c:f3:7f:ba:65:70 153      0

max-pkt-size  num-pkts  status      url target      Radio ID
-----  -
65536        3759     in-progress 192.168.0.3/5555 0
```

Description

This command defines a provisioning profile for an AP or group of APs. The AP provisioning profile allows you to define a set of provisioning parameters to an AP group. These settings can be saved or assigned to an AP group by using the `ap-group <group> provisioning-profile <profile>` command.

In order to enable cellular uplink for a Remote AP it must have the device driver for the USB data card and the correct configuration parameters. ArubaOS includes device drivers for the most common hardware types, but you can use the `usb` commands in this profile to configure a Remote AP to recognize and use an unknown USB modem type.

Parameter	Description
<pre>ap provisioning-profile <profile-name></pre>	<p>Configures a provisioning profile for an AP or a group of APs. Give a name for the profile.</p>
<pre>ap-lldp-pse-detect</pre>	<p>Enabling causes the AP to detect the POE type via LLDP POE TLV. Use one of the following parameters:</p> <ul style="list-style-type: none"> ■ enabled: The AP uses PSE TYPE in the POE TLV to detect the PSE type. ■ disabled: The AP detects the POE using the HW classification.
<pre>ap-poe-power-optimization</pre>	<p>Enabling optimization minimizes the POE draw of the AP. Enabling optimization may disable some parts of the AP. Disabling optimization ensures all features are enabled. Use one of the following parameters:</p> <ul style="list-style-type: none"> ■ enabled: USB and Ethernet port (eth1) are shut down on AP. ■ disabled: AP operates in normal mode. <p>disabled</p>
<pre>ap2xx-prestandard-poe-detection</pre>	<p>Configures the prestandard PoE detection on 200 Series APs. The POE+ pre-standard detection is only available on 200 Series APs. It consists of a basic voltage comparator. If the line voltage is equal to or greater than 51 V, the PSE is assumed to be 802.3at compatible.</p>

Parameter	Description
<code>apdot1x-factory-cert</code>	Enables AP to use factory certificates when doing 802.1x EAP-TLS. Custom cert available.
<code>apdot1x-timeout-bypass</code>	Enables AP to be provisioned when 802.1X authentication times out.
<code>apdot1x-timeout-retries</code>	Sets the apdot1x timeout threshold. If the auth timeouts over this threshold, the AP will bypass apdot1x auth.
<code>apdot1x-passwd</code>	Sets the password of the AP to authenticate to 802.1X using PEAP.
<code>apdot1x-tls</code>	Enables AP to perform 802.1x authentication using EAP-TLS.
<code>apdot1x-tls-suffix</code>	Enables AP to use EAP-TLS username as suffix. disabled
<code>apdot1x-tls-suffix-domain <apdot1x-tls-suffix-domain></code>	Sets the suffix domain for AP dot1x EAP-TLS username. If defined, use EAP-TLS username as suffix, else use aruba.ap . 1-63
<code>apdot1x-username <apdot1x-username></code>	Sets the username of the AP to authenticate to 802.1X using PEAP.
<code>cellular_nw_preference</code> {3g-only 4g-only advanced auto}	The cellular network preference setting allows you to select how the modem should operate. <ul style="list-style-type: none"> ■ auto (default) ■ 3g_only: Locks the modem to operate only in 3G. ■ 4g_only: Locks the modem to operate only in 4G. ■ advanced: The

Parameter	Description
	<p>Remote AP controls the cellular network service selection based on an Received Signal Strength Indication (RSSI) threshold-based approach. Initially the modem is set to the default auto mode. This allows the modem firmware to select the available network. The Remote AP determines the RSSI value for the available network type (for example 4G), checks whether the RSSI is within required range, and if so, connects to that network. If the RSSI for the modem's selected network is not within the required range, the Remote AP will then check the RSSI limit of an alternate network (for example, 3G), and reconnect to that alternate network. The Remote AP will repeat the above steps each time it tries to connect using a 4G multimode modem in this mode.</p> <p>The Remote AP determines the RSSI value for the available network type (for example 4G), checks whether the RSSI is within required range, and if so, connects to that network.</p> <p>If the RSSI for the modem's selected network is not within the required range, the Remote AP will then check the RSSI limit of an alternate network (for example, 3G), and reconnect to that</p>

Parameter	Description
	<p>alternate network. The Remote AP will repeat the above steps each time it tries to connect using a 4G multimode modem in this mode.</p> <p>auto</p>
<p>clone <source></p>	<p>Clones an existing AP provisioning profile.</p>
<p>link-priority-cellular <link-priority-cellular></p>	<p>Sets the priority of the cellular uplink. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link. Configuring the cellular link with a higher priority than your wired link priority will set your cellular link as the primary controller link.</p> <p>0-255 0</p>
<p>link-priority-ethernet <link-priority-ethernet></p>	<p>Sets the priority of the wired uplink. Each uplink type has an associated priority; wired ports having the highest priority by default.</p>
<p>link-priority-wifi <link-priority-wifi></p>	<p>Sets the priority of the wifi link.</p> <p>0-255</p>
<p>master/conductor</p>	<p>Changes the FQDN or IP address for the Mobility Conductor.</p>
<p>set <masterstr>/<conductorstr></p>	<p>Specifies the IP address or FQDN for the Mobility Conductor.</p>
<p>clear</p>	<p>Clear the definition for the Mobility Conductor in this profile.</p>

Parameter	Description
master preference/conductor preference <ipv4 ipv6>	Configures the preferred IP protocol (IPv4 or IPv6) for AP Conductor discovery. Default: IPv4
no	Negates any configured parameter.
pppoe-passwd <pppoe-passwd>	PPPoE password for the AP.
pppoe-servicename <pppoe-service-name>	PPPoE service name for the AP.
pppoe-user <pppoe-user>	PPPoE username for the AP.
remote-ap	Specifies that the profile is to be associated with a remote AP using certificates.
uplink-vlan <uplink-vlan>	If you configure an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink. By default, an AP has an uplink vlan of 0, which disables this feature. If an AP is provisioned with an uplink VLAN, it must be connected to a trunk mode port or the frames of the AP will be dropped. 0-4095 0
usb-csr	Configures the USB storage for CSR and private Key file
usb-dev <usb-dev>	Configures the USB device identifier.

Parameter	Description
usb-dial <usb-dial>	Configures the dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.
usb-init <usb-init>	The initialization string for the USB modem. This parameter only needs to be specified if the default string is not correct.
<pre>usb-modeswitch <usb-modeswitch> -v for default_vendor -p for default_product -V for target_vendor -P for target_product -M for message_content</pre>	<p>USB cellular devices on remote APs typically register as modems, but may occasionally register as a mass-storage device. If a remote AP cannot recognize its USB cellular modem, use the usb-modeswitch command to specify the parameters for the hardware model of the USB cellular data-card. You must enclose the entire modeswitch parameter string in quotation marks.</p>
usb-passwd <usb-passwd>	A PPP password, if provided by the cellular service provider.
<pre>usb-power-mode {auto enable disable}</pre>	Set the USB power mode to control the power to the USB port.
usb-tty <usb-tty>	The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.
<pre>usb-tty-control <usb-tty-control></pre>	The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.
usb-type	<p>Specify the USB driver type.</p> <p>acm: Use ACM driver</p> <p>airprime: Use Airprime driver</p>

Parameter	Description
	<p>ether: Use CDC Ether driver for direct IP 4G device</p> <p>hso: Use HSO driver for newer Option</p> <p>huawei-cdc: Use Huawei driver for 4G device</p> <ul style="list-style-type: none"> ■ inetgear-gobi: Use Gobi driver for Netgear 340U or 341U 4G device ■ none: Disable 3G or 2G network on USB ■ option: Use Option driver ■ option-novatel-u620: Use Option driver for Novatel U620L 4G device ■ pantech-3g: Same as "pantech-uml290" - to support upgrade ■ pantech-auto: Use Pantech driver for Automatic modem mode ■ pantech-uml290: Use Pantech USB driver for UML290 device ■ ptumusbnet: Use Pantech USB driver for 4G device ■ rndis: Use a RNDIS driver for a 4G device ■ rndis-1800: Same as RNDIS - to use for L800 4G device ■ rndis-pantech-uml295: Use RNDIS driver for Pantech UML 295 4G device ■ sierra-evdo: Use EVDO Sierra Wireless driver ■ sierra-gsm: Use GSM Sierra Wireless driver ■ sierrausbnet: Use SIERRA Direct IP driver for 4G device ■ storage: Use USB flash as storage device for storing Remote AP certificates

Parameter	Description
usb-user <usb-user>	The PPP username provided by the cellular service provider.

Examples

The following commands create a provisioning profile named `profile_branch`, in which the cellular link is the primary uplink because it has a higher priority than the Ethernet link:

```
(host) [mynode] (config) #ap provision-profile profile_branch
(host) [mynode] (Provisioning profile "profile_branch") #link-priority-cellular 2
(host) [mynode] (Provisioning profile "profile_branch") #link-priority-ethernet 1
(host) [mynode] (Provisioning profile "profile_branch") #usb-type acm
(host) [mynode] (Provisioning profile "profile_branch") #usb-modeswitch "-v 0x106c -p 0x3b06 -V 0x106c -P 0x3717 -M 5534243b82e238c24000000800008ff0200000000000000000000000000000000"
```

The following example configures the preferred IP protocol for AP master/conductor discovery:

```
(host) [mynode] (config) #ap provision-profile profile_branch
(host) [mynode] (Provisioning profile "profile_branch") #master/conductor-preference ipv6
```

ap provisioning-rule

```
ap provisioning-rule <profile-name>
  action
    a-ant-gain <a-ant-gain>
    ap-group <ap-group>
    g-ant-gain <g-ant-gain>
    radio-0-5ghz-ant-gain <radio-0-5ghz-ant-gain>
    radio-1-5ghz-ant-gain <radio-1-5ghz-ant-gain>
  clone <source>
  condition
    any-ap
    ap-type <ap-model>
    ip-range {<start> <end>}
    network {<ipaddr> <mask_len>}
  no...
```

Description

This command defines the conditions to select a group of APs and the subsequent actions to provision the APs. These settings can be saved or assigned to an AP group via the command `ap provisioning-rule <profile-name>`.

Parameter	Description
<code>ap provisioning-rule <profile-name></code>	Configures a condition for a group of APs and the related actions to provision the APs. Give a name for the profile.
<code>action</code>	Specify action that corresponds to the conditions, when rule is applied. When an AP satisfies all the criteria in conditions, the managed device executes the actions.
<code>a-ant-gain <a-ant-gain></code>	Antenna gain for 802.11a (5 GHz) antenna.
<code>ap-group <ap-group></code>	Name of the AP group to which the AP belongs.
<code>g-ant-gain <g-ant-gain></code>	Antenna gain for 802.11g (2.4 GHz) antenna.
<code>radio-0-5ghz-ant-gain <radio-0-5ghz-ant-gain></code>	Antenna gain for radio 0 (5 GHz) antenna. This parameter is only needed for APs that support dual 5 GHz mode.

Parameter	Description
<code>radio-1-5ghz-ant-gain <radio-1-5ghz-ant-gain></code>	Antenna gain for radio 1 (5 GHz) antenna. This parameter is only needed for APs that support dual 5 GHz mode.
<code>clone <source></code>	Copy data from another AP provisioning rule.
<code>condition</code>	Specify conditions to narrow the scale of AP based on each criteria in the conditions.
<code>any-ap</code>	Specify this provisioning rule's condition to any AP. The rule with this condition has lowest priority and is applied only when other conditions are not met.
<code>ap-type <ap-type></code>	Specify specific AP models that match with unprovisioned APs.
<code>ip-range {<start> <end>}</code>	Apply the AP provisioning rules to the specified IPv4/IPv6 address range. It contains the following parameters: <ul style="list-style-type: none"> ■ <code>start</code>: Starting IPv4/IPv6 address of the range. ■ <code>end</code>: Ending IPv4/IPv6 address of the range.
<code>network {<ipaddr> <mask_len>}</code>	Specify network that matches with unprovisioned APs in this subnet. It has the following parameters: <ul style="list-style-type: none"> ■ <code>addr</code>: IPv4/IPv6 address. ■ <code>mask_len</code>: Prefix/length of the netmask.
<code>no</code>	Remove any existing configuration.

Examples

The following commands add the condition and associated action for an auto-provisioning profile:

```
(host) [mm] (config) #ap provisioning-rule test
(host) [mm] (ap provisioning rule "test") #condition ap-type AP-103
(host) [mm] (ap provisioning rule "test") #action ap-group corp1
```

ap provisioning-rules

```
ap provisioning-rules <profile-name>  
no...  
provision-rule [<rule> {priority <priority>}]
```

Description

This command defines the priority of the provisioning rules that are actively used by the Auto-provisioning feature in APs.

Parameter	Description
no	Removes any existing configuration.
provision-rule <rule>	Specify action that corresponds to the conditions, when a rule is applied. When an AP satisfies all the criteria in conditions, the managed device executes the actions.
priority <priority>	Specify the priority level to determine the precedence of the rules. The lowest value takes highest priority. 1-64

Example

The following command defines the priority of the rule for an auto-provisioning profile:

```
(host) [mm] (ap provisioning rules) #provision-rule rule1 priority 1
```

ap randomize-channel

```
ap randomize channel ap-group <ap-group> phy-type <phy-type>
```

Description

This command will instruct the AP to change to a random channel and this command works only when ARM is in maintain mode.

Parameter	Description
ap-group <ap-group>	Name of the AP group.
phy-type <phy-type>	PHY Type of Radio. Possible values are '80211a' and '80211g'

Example

The following command instruct the AP to change to a random channel:

```
(host) [mynode] ap randomize-channel ap-group default phy-type 80211a
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

ap redeploy controller-less

```
ap redeploy controller-less
  all
  ap-group <ap-group>
  ap-name <ap-name>
  ip-addr <ip-addr>
  ip6-addr <ip6-addr>
  wired-mac <wired-mac>
```

Description

This command sets the AP preference role to controller-less, allowing the AP to bypass controller discovery and immediately initiate Instant discovery during AP image upgrade. APs with the controller-less preference role are deployed as controller-less APs.

The `ap redeploy controller-less` command is applicable to Unified APs (UAPs) only.

Parameter	Description
<code>all</code>	Deploys all APs as controller-less APs.
<code>ap-group <ap-group></code>	Deploys all APs in the specified AP group as controller-less APs.
<code>ap-name <ap-name></code>	Deploys a specific AP as a controller-less AP.
<code>ip-addr <ip-addr></code>	Deploys the AP with a specific IP address as a controller-less AP.
<code>ip6-addr <ip6-addr></code>	Deploys the AP with a specific IPv6 address as a controller-less AP.
<code>wired-mac <wired-mac></code>	Deploys the AP with a specific MAC address as a controller-less AP.

Example

The following command deploys all APs as controller-less APs.

```
(host) [mynode] #ap redeploy controller-less all
```

Command History

ap-regroup

```
ap-regroup {ap-name <name>|serial-num <num>|wired-mac <macaddr>} <group>
```

Description

This command moves a specified AP into a group. All APs discovered by the Mobility Conductor are assigned to the “default” AP group. An AP can belong to only one AP group at a time. You can move an AP to an AP group that you created with the `ap-group` command.

This command automatically reboots the AP.

Parameter	Description
ap-name	Name of the AP.
serial-num	Serial number of the AP.
wired-mac	MAC address of the AP.
<group>	Name that identifies the AP group. The name must be 1-63 characters.

Example

The following command moves an AP to the ‘corpnet’ group:

```
(host) [mynode] (config) #ap-regroup wired-mac 00:0f:1e:11:00:00 corpnet
```

ap regulatory-domain-profile

```
ap regulatory-domain-profile {default | <profile-name>
  clone <source>}
  country-code <country-code>
  no
  oob_switch
  utb_filter_block <5GHz | 6GHz>
  valid-11a-160mhz-channel-group <valid-11a-160mhz-channel-group>
  valid-11a-40mhz-channel-pair <valid-11a-40mhz-channel-pair>
  valid-11a-80mhz-channel-group <valid-11a-80mhz-channel-group>
  valid-11a-channel <valid-11a-channel>
  valid-11g-40mhz-channel-pair <valid-11g-40mhz-channel-pair>
  valid-11g-channel <valid-11g-channel>
  valid-6ghz-channel <valid-6ghz-channel>
```

Description

This command configures an AP regulatory domain profile. This profile configures the country code and valid channels for operation of APs. The list of valid channels only affects the channels that may be selected by ARM or by the Mobility Conductor when no channel is configured. Channels that are specifically configured in the AP radio settings profile (see [rf dot11a-radio-profile](#), [rf dot11g-radio-profile](#), [rf dot11g-radio-profile](#)) must be valid for the country and the AP model.

A Mobility Conductor shipped to certain countries, such as the U.S. and Israel, cannot terminate APs with regulatory domain profiles that specify different country codes from the Mobility Conductor. For example, if a controller is designated for the U.S., then only a regulatory domain profile with the “US” country code is valid; setting APs to a regulatory domain profile with a different country code will result in the radios not coming up. For controllers in other countries, you can mix regulatory domain profiles on the same controller; for example, one controller can support APs in Japan, Taiwan, China, and Singapore.

In order for an AP to boot correctly, the country code configured in the AP regulatory domain profile must match the country code of the LMS. If none of the channels supported by the AP have received regulatory approval by the country whose country code you selected, the AP will revert to Air Monitor mode.

This command is used to override available channels in the list of channels allowed for use in that country. If you do not add any channels to the AP regulatory domain profile, it means the AP can use any of the available channels. If you want to disable use of an entire band, best practices is to use the `rf-dot11a-radio-profile`, `rf-dot11g-radio-profile`, Or `rf dot11-6ghz-radio-profile` commands to disable the radio. Alternatively, if you want to disable a specific bandwidth, use the **Max Channel Bandwidth** and **Min Channel Bandwidth** settings in the radio profiles, and AirMatch will enforce this setting.

After an upgrade, the 6 GHz channel information is not populated in the existing regulatory domain profile by default. To add 6 GHz channels, you must change the country code to a different country code, apply the change, and then revert it to the original country code. Another option is to create a new profile or copy the existing regulatory domain profile into a new regulatory domain profile to save the configuration.

Parameter	Description
<code>ap regulatory-domain-profile <profile></code>	Configures a Regulatory Domain profile. Give a name to this instance of the profile. The name must be 1-63 characters long.
<code>clone <source></code>	Name of an existing regulatory domain profile from which parameter values are copied.
<code>country-code <country-code></code>	Code that represents the country in which the APs will operate. The country code determines the 802.11 wireless transmission spectrum. Improper country code assignment can disrupt wireless transmissions. Most countries impose penalties and sanctions for operators of wireless networks with devices set to improper country codes.
<code>no</code>	Negates any configured parameter.
<code>oob_switch</code>	If enabled, OOB scanning on 6 GHz band is allowed. If disabled OOB scanning on 6 GHz band is blocked. This switch is valid only for AP-615 access points in the 5GHz-and-2.4GHz operation mode. Disable the switch to enable the use of UNII-4 band. Default: Enabled.
<code>utb_filter_block</code>	This parameter is used to control the band on which the UTB limitation is applied in the regulatory-domain-profile. The utb filter supports channel band on both 5 GHz and 6 GHz. Listed below are the two options available: <ul style="list-style-type: none">▪ 5 GHz - Select 5 GHz for upper band blocking.▪ 6 GHz - Select 6 GHz for lower band blocking. Default value: 6 GHz

Parameter	Description
<code>valid-11a-40mhz-channel-pair</code> <code><valid-11a-40mhz-channel-pair></code>	<p>Specifies a channel pair valid for 40 MHz operation in the 802.11a frequency band for the specified regulatory domain. The two channels must be separated by a dash. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>
<code>valid-11a-80mhz-channel-group</code> <code><valid-11a-80mhz-channel-group></code>	<p>Specifies which 80 MHz channels on the <i>a</i> band are available for assignment by ARM and for Mobility Conductor to randomly assign if the user has not specified a channel. The channel numbers below correspond to channel center frequency. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>
<code>valid-11a-160mhz-channel-group</code> <code><valid-11a-160mhz-channel-group></code>	<p>Specifies a valid 802.11a channel group for 160 MHz channel on the <i>a</i> band. The channel numbers below correspond to channel center frequency. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>
<code>valid-11a-channel</code> <code><valid-11a-channel></code>	<p>Specifies a single 802.11a channel number for 20 MHz operation within the specified regulatory domain. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>
<code>valid-11g-40mhz-channel-pair</code> <code><valid-11g-40mhz-channel-pair></code>	<p>Specifies a channel pair valid for 40 MHz operation in the 802.11g frequency band for the specified regulatory domain. The two channels must be separated by a dash. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>
<code>valid-11g-channel</code> <code><valid-11g-channel></code>	<p>Specifies a single 802.11g channel number for 20 MHz operation within the specified regulatory domain. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>
<code>valid-6ghz-channel</code> <code><valid-6ghz-channel></code>	<p>Specifies a single 6 GHz channel number within the specified regulatory domain. Changing the country code causes the valid channel lists to be reset to the defaults for the country.</p>

Examples

The following example configures the regulatory domain profile for APs in Japan:

```
(host) [mynode] (config) #ap regulatory-domain-profile rd1
(host) [mynode] (Regulatory Domain profile "rd1") #country-code JP
```

The following example configures a regulatory domain profile for APs in the United States and specifies that the channel pair of 36 and 40, is allowed for 40 MHz mode of operation on the 5 GHz frequency band:

```
(host) [mynode] (config) #ap regulatory-domain-profile usa1
(host) [mynode] (Regulatory Domain profile "usa1") #country-code US
(host) [mynode] (Regulatory Domain profile "usa1") #valid-11a-40mhz-channel-pair 36-40
```

The following example configures a regulatory domain profile for APs in the United States and specifies that the channel pair of 5 and 1, is allowed for 40 MHz mode of operation on the 2.4 GHz frequency band:

```
host) [mynode] (config) #ap regulatory-domain-profile usa1
host) [mynode] (Regulatory Domain profile "usa1") #country-code US
host) [mynode] (Regulatory Domain profile "usa1") #valid-11g-40mhz-channel-pair 1-5
```

The following example configures a regulatory domain profile for a Wi-Fi 6E AP specifying the country code and 6 GHz channel on the 6 GHz radio band (ArubaOS 8.9.0.0 or later versions).

```
host) [mynode] (config) #ap regulatory-domain-profile reg-635
host) [mynode] (Regulatory Domain profile "reg-635") #country-code US
host) [mynode] (Regulatory Domain profile "reg-635") #valid-6ghz-channel 165
```

The following example configures a UTB Filter Blocking parameter for 5 GHz band (ArubaOS 8.9.0.0 or later versions).

```
(host) [mynode] (config) #ap regulatory-domain-profile reg-635
(host) [mynode] (Regulatory Domain profile "reg-635") #utb_filter_block
(host) [mynode] (Regulatory Domain profile "reg-635") #utb_filter_block 5GHz
```

The following example configures AP's regulatory domain profile:

```
(host) [/md] (config) #ap regulatory-domain-profile
clone                Copy data from another Regulatory Domain profile
country-code         Country Code
```

```

no                Delete Command
oob_switch        enabled - allows OOB scanning on 6GHz Band. disabled
- blocks OOB scanning on 6GHz Band. Default enabled.
utb_filter_block  6GHz - Selects 6GHz lowerband blocking. 5GHz -
Selects 5GHz upper band blocking. Default 6GHz.
valid-11a-160mhz-chan.. Valid 802.11a channel group for 160MHz (e.g., 36-64)
valid-11a-40mhz-chann.. Valid 802.11a channel pair for 40MHz (e.g., 36-40)
valid-11a-80mhz-chann.. Valid 802.11a channel group for 80MHz (e.g., 36-48)
valid-11a-channel  Valid 802.11a channel
valid-11g-40mhz-chann.. Valid 802.11g channel pair for 40MHz (e.g., 1-5)
valid-11g-channel  Valid 802.11g channel
valid-6ghz-channel Valid 6GHz channel

```

ap remote-debug-pkt

```
ap remote-debug-pkt [dump [start|stop]|match|mirror|reset|type] [ap-name <ap-name>|ip-addr<ip-addr>|ip6-addr<ip6-addr>]
```

Description

This command enables the packet debugging functionality to debug and troubleshoot data packets handled by the AP. Configure the packet debugging functionality by issuing the **ap remote-debug-pkt type** and **ap remote-debug-pkt match** to select the packet data type and filter respectively.

The **ap remote-debug-pkt type** command is necessary to select the debugging type, whereas **ap remote-debug-pkt match** is an optional command. If no match is configured, the filter is not applied and all the data packets are logged.

Issue the **ap remote-debug-pkt dump** command to view the selected data packets and **ap remote-debug-pkt mirror ip-addr <ip-addr>** command to mirror the data packets to a network device. The **ap remote-debug-pkt reset** command clears the packet debugging configuration.

Parameter	Description
<code>dump [start stop]</code>	Start or stop the debug packet dump to display data packets of the selected type .
<code>match [ap-name <ap-name> ip-addr<ip-addr> ip6-addr<ip6-addr>]</code>	Filter packets based on the AP name, IPv4 address, or IPv6 address.
<code>mirror [ap-name <ap-name> ip-addr<ip-addr> ip6-addr<ip6-addr>]</code>	Mirror the specified packets to the network device at the mentioned IPv4 or IPv6 address.
<code>reset [ap-name <ap-name> ip-addr<ip-addr> ip6-addr<ip6-addr>]</code>	Reset the packet debugging configuration.
<code>type [ap-name <ap-name> ip-addr<ip-addr> ip6-addr<ip6-addr>]</code>	Select the packet type for debugging. Debugging packet types include the following packet types: arp , dhcp , and all .

Example

The following command starts and stops the debug packet dump for specified AP name.

```
(host) [mynode] #ap remote-debug-pkt dump <start/stop> ap-name <ap-name>
```

ap-rename

```
ap-rename {ap-name <name>|serial-num <num>|wired-mac <macaddr>} >
```

Description

This command changes the name of an AP to the specified new name. An AP name must be unique within your network.

This command automatically reboots the AP.

Parameter	Description
ap-name	Current name of the AP.
serial-num	Serial number of the AP.
wired-mac	MAC address of the AP.

Example

The following command renames an AP:

```
(host) [mynode] (config) #ap-rename wired-mac 00:0f:1e:11:00:00 building3-lobby
```

ap spectrum clear-webui-view-settings

ap spectrum clear-webui-view-settings

Description

Clear a saved spectrum dashboard view. Saved spectrum view preferences may not be backwards compatible with the spectrum analysis dashboard in earlier versions of ArubaOS. If you downgrade to an earlier version of ArubaOS and your client is unable to load a saved spectrum view in the spectrum dashboard, access the CLI in enable mode and issue this command to delete the saved spectrum views and display default view settings in the spectrum dashboard.

Example

The following command removes the WebUI spectrum view settings file of an user:

```
(host) [mynode] #ap spectrum clear-webui-view-settings
```

ap spectrum local-override

```
no  
override ap-name <ap-name> spectrum-band <2.4ghz | 5ghz>
```

Description

Convert an AP or AM into a spectrum monitor by adding it to the spectrum local-override list. There are two ways to change an AP that supports the spectrum monitor feature into a spectrum monitor. You can assign that AP to a 802.11a and 802.11g radio profile that is already set to spectrum mode, or you can temporarily change the AP into a spectrum monitor using a local spectrum override profile. When you use a local spectrum override profile to override the mode setting of an AP, that AP will begin to operate as a spectrum monitor, but will remain associated with its previous 802.11a and 802.11g radio profiles. If you change any parameter (other than the overridden mode parameter) in the spectrum monitor's 802.11a or 802.11g radio profiles, the spectrum monitor will immediately update with the change. When you remove the local spectrum override, the spectrum monitor will revert back to its previous mode, and remain assigned to the same 802.11a and 802.11g radio profiles as before.

Parameter	Description
no	Negates any previous AP spectrum local-override configuration
override ap-name <ap-name>	Specifies the name of an AP whose radio should be converted to a spectrum monitor radio.
spectrum band	Specifies the spectrum band or portion of the band to be monitored by the spectrum monitor radio For 2GHz, channels 1–14 For 5 GHz, channels 36–64, 100–140 and 149–165 2 GHz

Description

This command configures an AP system profile. The AP system profile configures AP administrative operations, such as AirMatch and AP health check options and logging levels.

By default, each AP in a Mobility Conductor deployment measures its RF environment for a 5-minute duration, every 30 minutes. The Mobility Conductor uses this information to compute an optimal solution, then deploys the latest RF plan by sending updated settings to the APs. Use the **airmatch** settings in the AP system profile to modify these default report intervals, or to disable or re-enable AirMatch reports to the APs.

The AP Health check feature configured via the `health-check` parameters uses ping probes to check reachability and latency levels for the connection between the AP and the managed devices. Recorded latency information appears in the output of the `show ap ip health-check` command. If the managed device IP address becomes unreachable from the AP uplink, this feature records the time that the connection failed, and saves that information in a log file (`tmp` or `ap_hcm_log`) on the AP.

Starting from ArubaOS 8.2.0.0, the `no ipm-power-reduction-step-prio ipm-step <ipm-step> priority <priority number> sub-command` for the `ap system-profile <profile>` command set is simplified. If you want to remove one step or priority, you only need to specify the step and not the priority. For example: `no ipm-power-reduction-step-prio ipm-step <ipm-step>`.

Parameter	Description
<code>ap system-profile <profile></code>	Configures AP system profile. Give a name for this instance of the profile. The name must be 1-63 characters long.
<code>aeroscout-rtls-server</code>	Enables the AP to send RFID tag information to an AeroScout RTLS server.

Parameter	Description
	RTLS station reporting includes information for APs and the clients that the AP has detected.
ip-or-dns <ip-or-dns>	IPv4/IPv6 address or the DNS of the AeroScout server to which location reports are sent.
port <port>	Port number on the AeroScout server to which location reports are sent.
include-unassoc-sta enable disable	If you select the include-unassoc-sta enable option, the station reports will also include information about clients not associated to any AP. By default, unassociated clients are not included in station reports. disabled
airmatch-measure-duration <airmatch-measure-duration>	Change the AirMatch RF measurement duration from the default value of 5 minutes to any value in the range 5–60 minutes. A value of 0 disables AirMatch RF environment measurements. 5-60 5

Parameter	Description
airmatch-report-enabled	<p>Each AP in a Mobility Conductor deployment measures its RF environment for a duration specified by airmatch-measure-duration, every 30 minutes by default. Mobility Conductor uses this information to compute an optimal solution.</p> <p>enabled</p>
airmatch-report-period <airmatch-report-period>	<p>Change the frequency period which AirMatch starts measuring the RF environment.</p> <p>5-180 minutes.</p> <p>30</p>
am-scan-rf-band	<p>Scanning band for multiple RF radios.</p> <p>a, g, all</p> <p>all</p>
a	Sets the scanning band to 802.11a only.
g	Sets the scanning band to 802.11g only.
all	Sets the scanning band to apply to all bands.
ap-arp-attack-protection	<p>Drop ARP packets coming from wired or wireless clients with AP gateway IP address. In other words, disallow ARP attack from untrusted ports.</p> <p>enabled</p>

Parameter	Description
<pre>ap-console-password <ap-console-password></pre>	<p>Set the AP console password on the managed device. If the user does not set any password, the managed device generates a default random password which can be viewed by executing the encrypt disable command followed by the show ap system-profile <profile-name> command.</p> <p>6-32</p>
<pre>ap-console-protection</pre>	<p>Enable the AP console password.</p> <p>enabled</p>
<pre>ap-deploy-hour</pre>	<p>Configure hour-of-day for solution deployment for all radios of an AP. Overrides Airmatch profile if a valid hour is specified.</p> <p>0-23</p>
<pre>ap-poe-mode {failover shared}</pre>	<p>Configure the required PoE mode on the AP platforms that support dual PoE mode.</p> <ul style="list-style-type: none"> ■ Failover: Enables the source PoE power from either of the Ethernet ports. ■ Shared: Enables the combined power from both the PoE sources.
<pre>ap-usb-power-mode {auto enable disable}</pre>	<p>Set the USB power mode to control the power to the USB port. Listed below are the power modes:</p> <ul style="list-style-type: none"> ■ auto- Detect USB power mode automatically

Parameter	Description
	<ul style="list-style-type: none"> ■ disable- Disable USB power ■ enable- Enable USB power <p>This parameter can be configured only on AP-214, AP-215, AP-224, AP-225, AP-205H, AP-303H, AP-304, AP-305, AP-314, AP-315, AP-324, AP-325, AP-334, AP-335, AP-344, AP-345, AP-203R, and AP-203RP access points only.</p> <p>auto</p>
<pre>bkup-band a all g</pre>	<p>Band on which the Mobility Conductor broadcasts the backup ESSID.</p> <p>a, g, all</p> <p>all</p>
<pre>bkup-lms-ip <bkup-lms-ip></pre>	<p>In multi-controller) networks, specifies the IP address of a <i>backup</i> to the IP address specified with the <i>lms-ip</i> parameter.</p>
<pre>bkup-lms-ipv6 <bkup-lms-ipv6></pre>	<p>In multi-controller IPv6 networks, specifies the IPv6 address of a <i>backup</i> to the IPv6 address specified with the <i>lms-ipv6</i> parameter.</p>

Parameter	Description
<pre>bkup-mode dynamic off static</pre>	<p>This parameter allows AP console access using a backup ESSID, allowing users to access an AP console after the AP has disconnected from the Mobility Conductor. When the AP advertises a backup ESSID in either static or dynamic mode, a user is able to access and debug the AP remotely through a virtual AP. Select dynamic or static to enable this feature and select the mode by which the Mobility Conductor broadcasts the backup ESSID. This feature is disabled by default.</p> <p>dynamic, off, static off</p>
<pre>bkup-passwords <bkup-passwords></pre>	<p>Allows client access to adjust the band and mode settings for the backup ESSID.</p>
<pre>ble-op-mode {Beaconing Disabled DynamicConsole PersistentConsole}</pre>	<p>Determines how the built-in BLE chip in the AP functions. BLE chip can be in one of the following four modes:</p> <ul style="list-style-type: none"> ■ Beaconing: The built-in BLE chip of the AP functions as an iBeacon combined with beacon management functionality. ■ Disabled: The built-in BLE chip of the AP is turned off. This is the default setting. ■ DynamicConsole: The built-in chip of

Parameter	Description
	<p>the AP functions as a regular iBeacon combined with beacon management functionality. However, when the link to the Mobility Conductor is lost, the built-in chip temporarily enables access to the AP console over BLE. This state of the BLE device may be rolled back to any of the other modes if the AP receives a different configuration setting for the ble-op-mode parameter from the new LMS.</p> <ul style="list-style-type: none"> <p>PersistentConsole : The built-in chip of the AP provides access to the AP console over BLE using a mobile application. This functionality is the superset of the Beaconing mode.</p> <p>BLE is disabled on ArubaOS FIPS build.</p> <p>disabled</p>
ble-token <ble-token>	<p>The BLE endpoint authorization token is a text string of 1-255 characters used by the BLE to authorize to and securely communicate with the BMC. This token is unique for each deployment.</p> <p>1-255</p>

Parameter	Description
ble-url <ble-url>	URL of the Meridian server to which the BLE sends monitoring data.
bootstrap-threshold <bootstrap-threshold>	<p>Configures number of consecutive missed heartbeats on a GRE tunnel (heartbeats are sent once per second on each tunnel) before an AP reboots.</p> <p>On the Mobility Conductor, the GRE tunnel timeout is 1.5 x bootstrap-threshold; the tunnel is torn down after this number of seconds of inactivity on the tunnel.</p> <p>1-65535</p> <p>8</p>
bridge-offload	Enables the hardware acceleration of bridge traffic.
clone <source>	Name of an existing AP system profile from which parameter values are copied.
console-enable	<p>Enables console port on the AP.</p> <p>enabled</p>
<pre>console-log-lvl {alerts critical debugging emergencies errors informational notifications warnings}</pre>	<p>Specifies the level of driver log prints sent to AP console. The description of different log levels are as follows:</p> <ul style="list-style-type: none"> ■ emergencies: To send driver log prints when system is unusable ■ alerts: To send driver log prints when Immediate action is needed ■ critical: To send

Parameter	Description
	<p>driver log prints when critical conditions exist</p> <ul style="list-style-type: none"> ■ errors: To send driver log prints when there are error conditions ■ warnings: To send driver log prints for warning conditions ■ notifications: To send driver log prints when a normal, but significant condition occurs ■ informational: To send driver log prints for informational messages ■ debugging: To send driver log prints for debugging messages <p>Do not change the console log level without prior supervision from the Aruba Technical Support team.</p> <p>emergencies</p>
disable-factory-reset	<p>Disables factory reset when the AP is operational.</p> <p>disabled</p>
dscp-to-dot1p-priority-mapping	<p>Configures semicolon-separated mapping between IP DSCP value and VLAN 802.1p priority.</p> <p>Format: <DSCP range/list (0-63)>:<802.1p value (0-7)></p> <p>Format Example: 24:4;32,34:3;45-56:1;57-60,62:7</p>

Parameter	Description
<pre>dns-domain <dns-domain></pre>	<p>Name of domain that is resolved by corporate DNS servers. Use this parameter when configuring split tunnel.</p>
<pre>double-encrypt</pre>	<p>This parameter applies only to remote APs. Use double encryption for traffic to and from a wireless client that is connected to a tunneled SSID. When enabled, all traffic is re-encrypted in the IPsec tunnel. When disabled, the wireless frame is only encapsulated inside the IPsec tunnel. All other types of data traffic between the Mobility Conductor and the AP (wired traffic and traffic from a split-tunneled SSID) are always encrypted in the IPsec tunnel.</p> <p>disabled</p>
<pre>driver-log-level {alerts critical debugging emergencies errors informational notifications warnings}</pre>	<p>Configures the level of driver log prints sent to syslog server. The description of different log levels are as follows:</p> <ul style="list-style-type: none"> ■ emergencies: To send driver log prints when system is unusable ■ alerts: To send driver log prints when Immediate action is needed ■ critical: To send driver log prints when critical conditions exist ■ errors: To send driver log prints when there are error conditions

Parameter	Description
	<ul style="list-style-type: none"> ■ warnings: To send driver log prints for warning conditions ■ notifications: To send driver log prints when a normal, but significant condition occurs ■ informational: To send driver log prints for informational messages ■ debugging: To send driver log prints for debugging messages <p>warnings</p>
<p>dual-5ghz-mode {automatic disabled enabled}</p>	<p>Mode for Dual 5GHz APs:</p> <ul style="list-style-type: none"> ■ automatic: Dual 5GHz Mode is enabled or disabled automatically. ■ disabled: Dual 5GHz mode is disabled. ■ enabled: both radios operate on 5GHz band. <p>The dual-5ghz-mode parameter is supported only on 340 Series (AP-344 and AP-345) access points. However, the automatic mode is not supported on AP-344 access points.</p>

Parameter	Description
	<p>For example, if the configuration for dual-5ghz-mode is set to automatic, AP-344 access points do not support a dynamic mode change. Users must manually set dual-5ghz-mode to Enabled if they require AP-344 access points to operate in the dual 5GHz mode.</p> <p>Additionally, users must purchase the required dual 5GHz external antenna.</p> <p>In a conductor-local or a stand-alone controller mode, automatic is treated as disabled. In a Mobility Conductor-Managed Device mode, automatic indicates that AirMatch determines when to modify the operating mode from dual band to the dual 5GHz mode.</p> <p>automatic</p>
<pre>dump-server <dump-server> (For versions prior to ArubaOS 8.4.0.0)</pre>	<p>(For debugging purposes) Specifies the server to receive a core dump generated when an AP process crashes.</p>
<pre>dump-collection-profile (ArubaOS 8.4.0.0 or later versions) {default profile-name}</pre>	<p>Specifies the profile for collecting core dump when an AP process crashes.</p>
<pre>clone</pre>	<p>Copies data from another dump collection profile.</p>
<pre>dynamic-pcap-interval</pre>	<p>Configures dynamic PCAP collection interval in minutes.</p> <p>0-30</p>

Parameter	Description
no	Deletes the command.
server-ip	Configures the server IP(v4/v6) for the dump collection.
server-password	Configures the server password for the dump collection.
server-path	Configures the server file path for the dump collection.
server-port	Configures the server port for the dump collection.
server-username	Configures the server username for the dump collection.
system-dump-enable	Enables the collection of system dump when an AP process crashes.
transfer-mode	Configures the Dump Transfer Mode.
transfer-enable	<p>Enables AP to transfer core dump to controller and server.</p> <p>NOTE: By default, the <code>transfer-enable</code> sub-parameter is enabled allowing the AP to transfer the core dump and when disabled the core dump is stored on the AP.</p>
flex-radio-mode {2.4GHz 2.4GHz-and-5GHz 5GHz }	<p>The mode for flexible radios. Use the following parameters:</p> <ul style="list-style-type: none"> ■ 2.4GHz—The radio operates on 2.4GHz. ■ 2.4GHz-and-5GHz—The radio operates on both 2.4GHz and 5GHz.

Parameter	Description
	<ul style="list-style-type: none"> ■ 5GHz—The radio operates on 5GHz.
<pre>flex-dual {2.4GHz-and-6GHz 5GHz-and-2.4GHz 5GHz-and-6GHz}</pre>	<p>Enables the flex dual band support for an AP on stand-alone controllers. The flex dual band can be in one of the following three modes:</p> <ul style="list-style-type: none"> ■ 2.4GHz-and-6GHz—The radio 0 operates on 2.4 GHz and radio 1 operates on 6 GHz. ■ 5GHz-and-2.4GHz—The radio 0 operates on 5 GHz and radio 1 operates on 2.4 GHz. ■ 5GHz-and-6GHz—The radio 0 operates on 5 GHz and radio 1 operates on 6 GHz.
<pre>flex-dual-mode {2.4GHz-and-6GHz 5GHz-and-2.4GHz 5GHz-and-6GHz Automatic}</pre>	<p>Enables the flex dual band support for an AP in a Mobility Master-Managed Device topology. The flex dual band can be in one of the following four modes:</p> <ul style="list-style-type: none"> ■ 2.4GHz-and-6GHz—The radio 0 operates on 2.4 GHz and radio 1 operates on 6 GHz. ■ 5GHz-and-2.4GHz—The radio 0 operates on 5 GHz and radio 1 operates on 2.4 GHz. ■ 5GHz-and-6GHz—The radio 0 operates on 5 GHz and radio 1 operates on 6 GHz. ■ Automatic—The radio 0 operates on 5GHz,

Parameter	Description
	radio 1 operates on 2.4GHz, and AirMatch will assign the operating mode dynamically.
gre-offload	HW acceleration of GRE traffic (for test purpose only) disabled
he-pooling-enable	Enables HE pooling. Disabling this parameter overrides Airmatch decision to include APs in HE pooling.
health-check	The AP Health check feature configured via the <code>health-check</code> parameters uses ping probes to check reachability and latency levels for the connection between the AP and the managed device. Recorded latency information appears in the output of the <code>show ap ip health-check</code> command. If the managed device IP address becomes unreachable from the AP uplink, this feature records the time that the connection failed, and saves that information in a log file (<code>tmp</code> or <code>ap_hcm_log</code>) on the AP.
burst-size <size>	Number of probes to be sent during the probe frequency interval defined by the <code>frequency health-check</code> parameter. 1-16

Parameter	Description
	5
<pre>frequency <frequency></pre>	<p>Probe interval, in seconds. The WAN health-check feature sends the number of probes defined by the <code>burst-size</code> parameter during each frequency interval defined by this <code>frequency</code> parameter.</p> <p>10-300 10</p>
<pre>mode <mode></pre>	<p>Ping probe mode is the only mode currently supported by this feature.</p> <p>ping</p>
<pre>packet-size <packet-size></pre>	<p>The size, in bytes, of a ping datagram.</p> <p>10-2000 32</p>
<pre>report <report></pre>	<p>Number of seconds between health check reports sent from the AP to the controller. usage reports.</p> <p>60-3600 60</p>
<pre>retries <retries></pre>	<p>Number of times the attempts to resend a probe.</p> <p>1-10 3</p>

Parameter	Description
<pre>health-check-option</pre>	<p>Issue the <code>ap system-profile <profile> health-check-option</code> command to enable the AP Health check feature.</p> <p>disabled</p>
<pre>heartbeat-dscp <heartbeat-dscp></pre>	<p>Define the DSCP value of AP heartbeats. Use this feature to prioritize AP heartbeats and prevent the AP from losing connectivity with the Mobility Conductor over high-latency or low-bandwidth WAN connections.</p> <p>0-63</p> <p>0</p>
<pre>heartbeat-in <heartbeat-interval></pre>	<p>Set the interval between heartbeat messages between a remote or campus AP and its associated Mobility Conductor. An increase in the heartbeat interval increases the time it will take for an AP to detect the loss in connectivity to the Mobility Conductor, but can reduce internet bandwidth consumed by a remote AP.</p> <p>1-60</p> <p>1</p>
<pre>image-url <image-url></pre>	<p>Provide the image URL for an alternate AP image.</p>

Parameter	Description
ipm-enable	Enables the IPM system. To disable this feature, execute the <code>no ipm-enable</code> command. disabled
ipm-power-reduction-step-prio all	Sets up all the IPM power reduction steps.
ipm-power-reduction-step-prio ipm-step	Set IPM power and temperature reduction steps.
cpu_throttle_25	Configure this option to reduce the CPU frequency to 25%.
cpu_throttle_50	Configure this option to reduce the CPU frequency to 50%.
cpu_throttle_75	Configure this option to reduce the CPU frequency to 75%.
disable_alt_eth	Disables the second Ethernet port.
disable_pse1	Disable the first PSE port.
disable_pse2	Disable the second PSE port.
disable_usb	Disable the USB port.
radio_2ghz_chain_1x1 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 2.4 GHz chains to 1x1.
radio_1_chain_1x1 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 1 chains to 1x1.
radio_2ghz_chain_2x2 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 2.4 GHz chains to 2x2.
radio_1_chain_2x2 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 1 chains to 2x2.

Parameter	Description
radio_2ghz_chain_3x3 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 2.4 GHz chains to 3x3.
radio_1_chain_3x3 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 1 chains to 3x3.
radio_2ghz_disable (For versions prior to ArubaOS 8.11.0.0)	Configure this option to disable the 2.4 GHz radio band.
radio_1_disable (ArubaOS 8.11.0.0 or later versions)	Configure this option to disable radio 1.
radio_2ghz_power_3dB (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 2.4 GHz radio power by 3 dB from the maximum value.
radio_1_power_3dB (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 1 power by 3 dB from the maximum value.
radio_2ghz_power_6dB (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 2.4 GHz radio power by 6 dB from the maximum value.
radio_1_power_6dB (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 1 power by 6 dB from the maximum value.
radio_5ghz_2_chain_1x1 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the secondary 5 GHz radio chains to 1x1.
radio_2_chain_1x1 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 chains to 1x1.
radio_5ghz_2_chain_2x2 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the secondary 5 GHz radio chain to 2x2.

Parameter	Description
radio_2_chain_2x2 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 chains to 2x2.
radio_5ghz_2_chain_3x3 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the secondary 5 GHz radio chain to 3x3.
radio_2_chain_3x3 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 chains to 3x3.
radio_5ghz_2_disable (For versions prior to ArubaOS 8.11.0.0)	Configure this option to disable the secondary 5 GHz radio.
radio_2_disable (ArubaOS 8.11.0.0 or later versions)	Configure this option to disable radio 2.
radio_5ghz_2_power_3dB (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 5 GHz radio power by 3 dB from the maximum value.
radio_2_power_3dB (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 power by 3 dB from the maximum value.
radio_5ghz_2_power_6dB (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 5 GHz radio power by 6 dB from the maximum value.
radio_2_power_6dB (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 power by 6 dB from the maximum value.
radio_5ghz_chain_1x1 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chains to 1x1.
radio_0_chain_1x1 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 1x1.
radio_5ghz_chain_2x2 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chains to 2x2.

Parameter	Description
radio_0_chain_2x2 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 2x2.
radio_5ghz_chain_3x3 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chains to 3x3.
radio_0_chain_3x3 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 3x3.
radio_5ghz_chain_4x4 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chain to 4x4.
radio_0_chain_4x4 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 4x4.
radio_5ghz_chain_5x5 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chains to 5x5.
radio_0_chain_5x5 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 5x5.
radio_5ghz_chain_6x6 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chain to 6x6.
radio_0_chain_6x6 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 6x6.
radio_5ghz_chain_7x7 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 5 GHz chain to 7x7.
radio_0_chain_7x7 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 0 chains to 7x7.
radio_5ghz_disable (For versions prior to ArubaOS 8.11.0.0)	Configure this option to disable the 5 GHz radio band.
radio_0_disable (ArubaOS 8.11.0.0 or later versions)	Configure this option to disable radio 0.

Parameter	Description
radio_5ghz_power_3dB (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 5 GHz radio power by 3 dB from the maximum value.
radio_0_power_3dB (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 0 power by 3 dB from the maximum value.
radio_5ghz_power_6dB (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 5 GHz radio power by 6 dB from the maximum value.
radio_0_power_6dB (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 0 power by 6 dB from the maximum value.
radio_6ghz_chain_1x1 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 6 GHz chains to 1x1.
radio_2_chain_1x1 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 2 chains to 1x1.
radio_6ghz_chain_2x2 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 6 GHz chains to 2x2.
radio_2_chain_2x2 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 2 chains to 2x2.
radio_6ghz_chain_3x3 (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce 6 GHz chains to 3x3.
radio_2_chain_3x3 (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce radio 2 chains to 3x3.
radio_6ghz_disable (For versions prior to ArubaOS 8.11.0.0)	Configure this option to disable the 6 GHz radio.
radio_2_disable (ArubaOS 8.11.0.0 or later versions)	Configure this option to disable radio 2.

Parameter	Description
<code>radio_6ghz_power_3dB</code> (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 6 GHz radio power by 3 dB from the maximum value.
<code>radio_2_power_3dB</code> (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 power by 3 dB from the maximum value.
<code>radio_6ghz_power_6dB</code> (For versions prior to ArubaOS 8.11.0.0)	Configure this option to reduce the 6 GHz radio power by 6 dB from the maximum value.
<code>radio_2_power_6dB</code> (ArubaOS 8.11.0.0 or later versions)	Configure this option to reduce the radio 2 power by 6 dB from the maximum value.
<code>priority <priority></code>	Sets the priorities for IPM power reduction steps.
<code>itm-enable</code>	<p>Enables the intelligent temperature monitoring system. If enabled, the temperature is dynamically controlled and the AP is allowed to cool down. To disable this feature, issue the <code>no itm-enable</code> command.</p> <p>NOTE:</p> <ul style="list-style-type: none"> ■ This feature can be enabled only when the IPM feature is enabled. ■ This feature is supported only on AP-505H, AP-518, 570 Series, and 580 Series access points. <p>disabled</p>

Parameter	Description
led-mode	<p>The operating mode for the AP LEDs. This option is available on all 802.11n indoor AP platforms.</p> <p>normal</p>
normal	Display LEDs in normal mode.
off	Turn off all LEDs.
led-override	<p>Override the LED action for single-LED APs in normal LED operating mode. If enabled, this feature disables the LED auto-turn-off function.</p> <p>disabled</p>
lms-hold-down-period	<p>Time, in seconds, that the primary LMS must be available before an AP returns to that LMS after failover.</p> <p>1-3600</p> <p>600</p>
lms-ip <lms-ip>	<p>In multi-controller networks, this parameter specifies the IP address of the LMS—the managed device—which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. This can be the IP address of the managed device or Mobility Conductor.</p>

Parameter	Description
	<p>When using redundant managed device as the LMS, set this parameter to be the VRRP IP address to ensure that APs always have an active IP address with which to terminate sessions. If the LMS-IP is blank, the access point will remain on the managed device that it finds using methods like DNS or DHCP. If an IP address is configured for the LMS IP parameter, the AP will be immediately redirected to the managed device at that address.</p>
<pre>lms-ipv6 <lms-ipv6></pre>	<p>In multi-controller IPv6 networks, specify the IPv6 address of the LMS—the managed device—which is responsible for terminating user traffic from the APs, and processing and forwarding the traffic to the wired network. This can be the IP address of the managed device or Mobility Conductor. When using redundant managed device as the LMS, set this parameter to be the VRRP IP address to ensure that APs always have an active IP address with which to terminate sessions.</p>

Parameter	Description
<p>lms-ping-interval <lms-ping-interval></p>	<p>Specifies the interval at which application level ping needs to be sent to managed device to check the reachability. Applicable only for Remote AP. If this parameter is changed, UDP session timeout on an intermediate router which performs the NAT function should be set accordingly. The preferred timeout value is (lms-ping-interval + 30 seconds).</p> <p>10-60 20</p>
<p>lms-preemption</p>	<p>Automatically reverts to the primary LMS IP address when it becomes available.</p> <p>disabled</p>
<p>maintenance-mode</p>	<p>Enable or disable AP maintenance mode. This setting is useful when deploying, maintaining, or upgrading the network. If enabled, APs stop flooding unnecessary traps and syslog messages to NMS systems or network operations centers when deploying, maintaining, or upgrading the network. The Mobility Conductor still generates debug syslog messages if debug logging is enabled.</p> <p>disabled</p>

Parameter	Description
<pre>max-request-retries <max-request-retries></pre>	<p>Maximum number of times to retry AP-generated requests, including keepalive messages. After the maximum number of retries, the AP either tries the IP address specified by the bkup-lms-ip (if configured) or reboots.</p> <p>1-65535 10</p>
<pre>mcast-aggr</pre>	<p>Enable multicast aggregation at AP.</p> <p>disabled</p>
<pre>mcast-aggr-allowed-vlan <vlan-list></pre>	<p>Enable list of VLANs where AP multicast aggregation is allowed.</p> <p>disabled</p>
<pre>mgmt-dscp <mgmt-dscp></pre>	<p>Sets the DSCP value of AP management packets.</p> <p>0-63</p>
<pre>mtu</pre>	<p>MTU, in bytes, on the wired link for the AP.</p> <p>1024-1578</p>
<pre>native-vlan-id <native-vlan-id></pre>	<p>Native VLAN for bridge mode virtual APs (frames on the native VLAN are not tagged with 802.1q tags).</p> <p>1</p>
<pre>no</pre>	<p>Negates any configured parameter.</p>
<pre>number-ipsec-retries <number_ipsec_retries></pre>	<p>The number of times the AP will attempt to recreate an IPsec tunnel with the Mobility Conductor before the AP will reboot. A value of 0 disables the reboot.</p>

Parameter	Description
	1-1000 85
rap-bw-resv-1 acl <aclname> [priority <priority>]	Session ACLs with uplink bandwidth reservation in Kbps. You can specify up to three session ACLs to reserve uplink bandwidth. The sum of the three uplink bandwidths should not exceed the rap-bw-total value. BW value is in Kbps. Optionally, you can specify the priority for class 1, class 2, and class 3 traffic.
rap-bw-resv-2 acl <aclname> <bwvalue> [priority <priority>]	
rap-bw-resv-3 acl <aclname> [priority <priority>]	
rap-bw-total <rap-bw-total>	This is the total reserved uplink bandwidth (in Kbps).
rap-corp-dns-server <ipv4 address>	IPv4 address of the Corporate DNS server
rap-corp-dns-server_ ipv6 <ipv6 address>	IPv6 address of the Corporate DNS server
rap-dhcp-default-router <rap-dhcp-default-router>	IP address for the default DHCP router. 192.168.11.1
rap-dhcp-dns-server <rap-dhcp-dns-server>	IP address of the DNS server. 192.168.11.1
rap-dhcp-lease <rap-dhcp-lease>	The amount of days that the assigned IP address is valid for the client. Specify the lease in <days>. 0 indicates the IP address is always valid; the lease does not expire. 0-30 0

Parameter	Description
<pre>rap-dhcp-pool-end <rap-dhcp-pool-end></pre>	<p>Configures a DHCP pool for remote APs. This is the last IP address of the DHCP pool.</p> <p>192.168.11.254</p>
<pre>rap-dhcp-pool-netmask <rap-dhcp-pool-netmask></pre>	<p>Configures a DHCP pool for remote APs. This is the netmask used for the DHCP pool.</p> <p>255.255.255.0</p>
<pre>rap-dhcp-pool-start <rap-dhcp-pool-start></pre>	<p>Configures a DHCP pool for remote APs. This is the first IP address of the DHCP pool.</p> <p>192.168.11.2</p>
<pre>rap-dhcp-server-id <rap-dhcp-server-id></pre>	<p>IP address used as the DHCP server identifier.</p> <p>192.168.11.1</p>
<pre>rap-dhcp-server-vlan <rap-dhcp-server-vlan></pre>	<p>VLAN ID of the remote AP DHCP server used if the Mobility Conductor is unavailable. This VLAN enables the DHCP server on the AP (also known as the remote AP DHCP server VLAN). If you enter the native VLAN ID, the DHCP server is unavailable.</p>
<pre>rap-gre-mtu <rap-gre-mtu></pre>	<p>Configures the maximum size of the GRE packets exchanged between a Remote AP and the Mobility Conductor.</p> <p>1024-1578 1200</p>
<pre>rap-local-network-access</pre>	<p>Enable or disable local network access across VLANs in a Remote AP.</p>

Parameter	Description
	disabled
<pre>recovery-mode {legacy auto}</pre>	<p>Select either the legacy recovery mode or the auto mode (fast recovery).</p> <ul style="list-style-type: none"> ■ legacy— On detecting a firmware assert, the AP transfers the core-dump to the managed device and executes an AP reboot. ■ auto—On detecting a firmware assert, the AP executes the fast recovery process in the radio affected instead of rebooting the AP. This reduces the downtime of the AP in the network. If the AP detects a core dump with a valuable information during a firmware assert, then it transfers the core dump to the managed device and the AP reboots. <p>The fast recovery mode for 530 Series and 550 Series access points is disabled by default.</p> <p>legacy</p>
<pre>request-retry-interval <request-retry-interval></pre>	<p>Interval, in seconds, between the first and second retries of AP-generated requests. If the configured interval is less than 30 seconds, the interval for subsequent retries is increased up to 30 seconds.</p> <p>1-65535</p>

Parameter	Description
	10
rf-band {a g}	For APs that support both <i>a</i> and <i>b/g</i> RF bands, RF band in which the AP should operate: <ul style="list-style-type: none"> ■ g = 2.4 GHz ■ a = 5 GHz g
rtls-server	Enables the AP to send RFID tag information to an RTLS server.
ip-or-dns	IPv4/IPv6 address or the DNS of the RTLS server to which location reports are sent.
port	Port number on the server to which location reports are sent.
key	Shared secret key.
station-message-frequency	Indicates how often packets are sent to the server.\ 1-3600 30
[include-unassoc-sta {enable disable}]	RTLS station reporting includes information for APs and the clients that the AP has detected. If you include the <code>include-unassoc-sta</code> parameter, the station reports will also include information about clients not associated to any AP. By default, unassociated clients are not included in station reports.

Parameter	Description
	disabled
rtls-server-compat_mode	The compatibility mode controls the format of tag frames forwarded to the RTLS server. Enabling this mode will enable legacy format (includes a 2 byte padding), and disabling this mode will remove the padding. The tag frame format will be the same across all AP models.
secondary-master/secondary-conductor <secondary-master>/<secondary-conductor>	Assigns a remote AP as a secondary Mobility Conductor in the event the primary Mobility Conductor can not be reached.
sesImagotag-esl-channel	Sets the channel of SES-imagotag ESL Radio. There are 12 pre-defined, independent radio channels. Channel 0 to 10 and 127 are valid channels and channel 11 is an invalid channel. The recommended channels are 3, 5, 8, 9, and 10 as they connect faster. These channels do not correspond to standard 802.11 channels. 0-10 and 127
sesimagotag-esl-radio-coexistence	Enables radio co-existence features between SES-imagotag ESL radio and 2.4 G WiFi radio

Parameter	Description
sesimagotag-esl-server	Sets the FQDN of SES-imagotag ESL Server. Server name takes priority over IP address. If server name is configured, IP address will not take effect. If server name is not configured, IP address takes effect. To disable SES-imagotag ESL server, do not configure server name and IP address.
sesimagotag-esl-serverip	Sets the IP Address of SES-imagotag ESL Server. Adding server IP addresses allows bulk management and control of multiple servers at the same time. Starting from ArubaOS 8.7.1.9, a new option to configure the port number for SES Imagotag dongles is introduced. Custom port can be set using the port option. The port setting is optional. The domain name configuration should be followed by a colon and the port number :-<port number> . If the port number is not defined the default port will be used by SES Imagotag dongles. For example, (host) [mynode] (AP system profile "test")sesimagotag-esl-server arubanetworks.com:64104
sesimagotag-esl-tls-auth	Allows AP to authenticate with SES-Imagotag ESL server.

Parameter	Description
<pre>sesimagotag-esl-tls-fqdn-verify</pre>	<p>Allows AP to verify TLS FQDN</p>
<pre>session-acl <session-acl></pre>	<p>Session ACL configured with the ip access-list session command. This parameter requires the PEFNG license. If PEFNG license is installed, ap uplink-acl is applied, else no ACL is applied.</p>
<pre>slow_timer_recovery</pre>	<p>If you enable this option, ArubaOS checks for a slow CPU timer, and if it detects an issue, it restarts the AP without logging a reason for the reboot. This feature is supported on RAP-108 or RAP-109 access points.</p> <p>disabled</p>
<pre>spanning-tree</pre>	<p>Enables the spanning-tree protocol.</p> <p>disabled</p>
<pre>split-5ghz-mode</pre>	<p>Set mode for split-5GHz capable APs from one of the following:</p> <ul style="list-style-type: none"> ▪ Automatic : Split-5GHz radio mode is enabled or disabled automatically ▪ Disabled: Split-5GHz radio mode will be disabled. ▪ Enabled: 8x8:8SS 5GHz radio will be split to 2 4x4:4SS 5GHz radios.

Parameter	Description
syscontact	SNMP system contact information.
telnet	Enables or disables telnet or SSH to the AP. Telnet is enabled on an AP running ArubaOS 8.6.0.0 or previous versions. SSH is enabled on an AP running ArubaOS 8.7.0.0 firmware version. disabled
wids-ampdu-optimization	Enables or disables WIDS aggregate MPDU optimization. disabled
wired-poe-bounce-interval <wired-poe-bounce-interval>	Configures the down time of PoE wired port after the AP fails over to backup cluster or falls back to primary cluster. 0-60 secs 0 NOTE: The port bounce feature is disabled when the default value is 0.
wired-port-bounce-interval <wired-port-bounce-interval>	Configures the down time of Ethernet link wired port after the AP fails over to backup cluster or falls back to primary cluster. 0-60 secs 0 NOTE: The port bounce feature is disabled when the default value is 0.

Example

The following command configures the Dual 5GHz mode option for 340 Series access points:

```
(host) [mynode] (config) #ap system profile <profile-name>
(host) [mynode] (AP system profile "<profile-name>") #dual-5ghz-mode enabled
```

The following commands configure LACP and AP LACP LMS map information settings:

```
(host) [mynode] (config) #ap system-profile LACP
(host) [mynode] (AP system profile "LACP") #lms-ip 192.0.2.1
(host) [mynode] (AP system profile "LACP") #exit
(host) [mynode] (config) #ap-lacp-striping-ip
(host) [mynode] (AP LACP LMS map information) #striping-ip 192.0.2.2 lms
192.0.2.1
(host) [mynode] (AP LACP LMS map information) #aplacp-enable
```

For more information on configuring LACP support, including important pre-deployment considerations and troubleshooting information, refer to the *ArubaOS User Guide*. It is recommended not to configure GRE striping IP address for stand-alone controller deployments.

The following command removes one IPM step or priority from the AP system profile, "default":

```
(host) [mynode] (config) #ap system-profile default
(host) [mynode] (AP system profile "default") #no ipm-power-reduction-step-
prio ipm-step cpu_throttle_50
```

The following command removes all IPM priorities set for an AP system profile:

```
(host) [mynode] (AP system profile "default") #no ipm-power-reduction-step-
prio all
```

The following commands configure the recovery mode parameter for 300 Series access points:

```
(host) [mynode] (config) #ap system-profile <profile-name>
(host) [mynode] (AP system profile "<profile-name>") #recovery-mode auto
```

The following commands configure the wired port downtime for both Ethernet link and PoE:

```
(host) [mynode] (config)#ap system-profile <profile-name>
(host) [mynode] (AP system profile "<profile-name>") # wired-poe-bounce-
interval <wired-poe-bounce-interval>
(host) [mynode] (AP system profile "<profile-name>") # wired-port-bounce-
interval <wired-port-bounce-interval>
(host) [mynode] (AP system profile "<profile-name>") # write memory
```

Command History

Release	Modification
ArubaOS 8.11.0.0	<p>The following modifications were introduced:</p> <ul style="list-style-type: none"> ■ The following new parameters were added: <ul style="list-style-type: none"> ● <code>flex-dual {2.4GHz-and-6GHz 5GHz-and-2.4GHz 5GHz-and-6GHz}</code> ● <code>flex-dual-mode {2.4GHz-and-6GHz 5GHz-and-2.4GHz 5GHz-and-6GHz Automatic}</code> ■ The following changes were made to the <code>ipm-power-reduction-step-prio ipm-step</code> parameter: <ul style="list-style-type: none"> ● Replaced <code>radio_2ghz_chain_1x1</code> with <code>radio_1_chain_1x1</code> ● Replaced <code>radio_2ghz_chain_2x2</code> with <code>radio_1_chain_2x2</code> ● Replaced <code>radio_2ghz_chain_3x3</code> with <code>radio_1_chain_3x3</code> ● Replaced <code>radio_2ghz_disable</code> with <code>radio_1_disable</code> ● Replaced <code>radio_2ghz_power_3dB</code> with <code>radio_1_power_3dB</code> ● Replaced <code>radio_2ghz_power_6dB</code> with <code>radio_1_power_6dB</code> ● Replaced <code>radio_5ghz_2_chain_1x1</code> with <code>radio_2_chain_1x1</code> ● Replaced <code>radio_5ghz_2_chain_2x2</code> with <code>radio_2_chain_2x2</code> ● Replaced <code>radio_5ghz_2_chain_3x3</code> with <code>radio_2_chain_3x3</code> ● Replaced <code>radio_5ghz_2_disable</code> with <code>radio_2_disable</code> ● Replaced <code>radio_5ghz_2_power_3dB</code> with <code>radio_2_power_3db</code> ● Replaced <code>radio_5ghz_2_power_6dB</code> with <code>radio_2_power_6db</code> ● Replaced <code>radio_5ghz_chain_1x1</code> with <code>radio_0_chain_1x1</code> ● Replaced <code>radio_5ghz_chain_2x2</code> with <code>radio_0_chain_2x2</code> ● Replaced <code>radio_5ghz_chain_3x3</code> with <code>radio_0_chain_3x3</code>

Release	Modification
ArubaOS 8.6.0.0	The <code>sesimagotag-esl-server</code> parameter was added.
ArubaOS 8.5.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>rap-corp-dns-server <ipv4 address></code> ■ <code>rap-corp-dns-server_ ipv6 <ipv6 address></code>
ArubaOS 8.4.0.0	The following modifications were introduced: <ul style="list-style-type: none"> ■ The IPv6 address support was added to the <code>ip-or-dns</code> parameter. ■ The <code>ap-usb-power-mode</code> and <code>wids-ampdu-optimization</code> parameters were added. ■ The <code>sesImagotag-esl-channel</code> and <code>sesImagotag-esl-serverip</code> parameters were added. ■ The <code>ap-usb-power-override</code> parameter was deprecated. The following parameters were added: <ul style="list-style-type: none"> ■ <code>radio_5ghz_chain_4x4</code> ■ <code>radio_5ghz_chain_5x5</code> ■ <code>radio_5ghz_chain_6x6</code> ■ <code>radio_5ghz_chain_7x7</code> ■ The <code>dump-server <dump-server></code> parameter was deprecated. ■ The <code>dump-collection-profile {default profile-name}</code> parameter was introduced.
ArubaOS 8.3.0.0	The following new parameters were added: <ul style="list-style-type: none"> ■ <code>dual-5ghz-mode</code> ■ <code>recovery-mode</code> ■ <code>ap-deploy-hour</code>
ArubaOS 8.2.0.0	<ul style="list-style-type: none"> ■ The <code>all</code> sub-parameter was added to the <code>ipm-power-reduction-step-prio</code> parameter. ■ The <code>no ipm-power-reduction-step-prio ipm-step <ipm-step> priority <priority number></code> parameter was changed to <code>no ipm-power-reduction-step-prio ipm-step <ipm-step></code>. ■ The <code>flex-radio-mode</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters.	Config mode on Mobility Conductor.

ap test

```
ap test
  airmatch
  ap-name
  bss-termination
  dot11k-force-beacon-request
  dot11k-force-link-measurement-request
  dot11k-force-tsm-request
  dot11v-force-bss-transition
  force_send_delts
  ip-addr
  ip6-addr
  netdest
  network-check
  rebootstrap
  remote-dot11v-force-bss-transition
  wan
```

Description

Execute this command to get the test results in an AP.

Parameter	Description
ap test	Run test command on AP.
ap-name bar-retries bar-times	Name of the access point.
bss-termination	Trigger timed BSS-termination, sending BTM-requests to MBO-STAs.
dot11k-force-beacon-request sta <sta_mac>	Test force sending 802.11 Beacon Report Request frame.
dot11k-force-link-measurement-request sta <sta_mac>	Test force sending 802.11 Link Measurement Request frame.
dot11k-force-tsm-request sta <sta_mac>	Test force sending TSM Report Request frame.
dot11v-force-bss-transition sta <sta_mac>	Test force sending BSS Transition Mgmt Request frame.

Parameter	Description
<code>force_send_delts</code>	Force sending DELTS to the client.
<code>ip-addr</code>	IP Address of Access Point.
<code>ip6-addr</code>	IPv6 address of Access Point.
<code>netdest</code>	Trigger netdestination config push.
<code>network-check</code>	Check the network.
<code>rebootstrap ap-name ip-addr ip6-addr</code>	Rebootstrap AP.
<code>remote-dot11v-force-bss-transition</code>	Test force sending BSS Transition Management Request frame.
<code>wan down up</code>	Wan link test command. <ul style="list-style-type: none"> ■ down — Trigger wan down event. ■ up — Trigger wan up event.

Example

The following command displays different results of AP-related tests:

```
(host) [mynode] #ap test
```

Command History

apugr

```
apugr
  act part <partition>
  add ap-name <ap-name>
  move ap-name <ap-name> target <target>
```

Description

This command can be executed for cluster upgrade.

Parameter	Description
act	Active upgrade preload ap.
part <partition>	AP preload partition.
add	Adds upgrade preload AP.
ap-name <ap-name>	Name of the AP.
move	Moves an AP to another target
ap-name <ap-name>	Name of the AP.
target <target>	Ip address of the target controller.

Available on all platforms.	Base operating system.	Enable mode on Mobility Conductor.

ap usb-acl-prof

```
ap usb-prof default | {<profile-name> clone | no | rule vendor <vendor> action <action>}
```

Description

This command is used to create a AP USB ACL profile.

Parameter	Description
default	Name of the default AP USB ACL profile.
<profile-name>	Name of the AP USB ACL profile.
clone	Copy AP USB ACL profile data from another AP USB ACL profile.
no	Negate any configured parameter.
rule	USB access rule.
vendor <vendor>	Name of USB vendor. Available options are: <ul style="list-style-type: none">■ Alcatel-L800■ Amberbox-detector■ Amberbox-gateway■ C-motech-CNU-680■ EpiValley-SEC-8089■ Franklin-u770-u772■ Franklin-U300■ Franklin-U301■ Franklin-U600■ Fujisoft■ Globetrotter-ICON-225■ Globetrotter-ICON-322■ HanShow■ Huawei-3276s-150■ Huawei-D41HW■ Huawei-E1552■ Huawei-E157■ Huawei-E160■ Huawei-E169-E180-E220■ Huawei-E170-E272-E220■ Huawei-E173■ Huawei-E1731-177DT06■ Huawei-E1750■ Huawei-E176-E176G-E1553■ Huawei-E1762■ Huawei-E180■ Huawei-E180-E1692-E1762

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable Mode.

ap usb-profile

ap usb-profile default | {<profile-name> clone | no | usb-acl-profile}

Description

This command is used to create a AP USB profile.

Parameter	Description
default	Name of the default AP USB profile.
<profile-name>	Name of the AP USB profile.
clone	Copy AP USB profile data from another AP USB profile.
no	Negate any configured parameter.
usb-acl-profile	Apply USB ACL profile to AP USB profile.

Example

The following command creates an AP USB profile named sample-ap-usb-profile and applies a USB ACL profile named sample-usb-acl-profile to it:

```
(host) [mynode] (config) #ap usb-profile sample-ap-usb-profile
(host) (mynode) (AP USB profile "sample-ap-usb-profile") #usb-acl-profile
sample-usb-acl-profile
```

ap wifi-uplink-profile

```
ap wifi-uplink-profile {default | <profile-name>}
  allowed band {a | g | all}
  bssid <bssid>
  clone {default | <source> }
  essid <essid>
  no
  opmode {opensystem | personal | static-wep}
  wepkey1 <wepkey1>
  wepkey2 <wepkey2>
  wepkey3 <wepkey3>
  wepkey4 <wepkey4>
  weptxkey <weptxkey>
  wpa-hexkey <wpa-hexkey>
  wpa-passphrase <wpa-passphrase>
```

Description

This command configures a Wi-Fi uplink profile. When both wpa-hexkey and wpa-passphrase parameters are configured, wpa-hexkey takes precedence.

Parameter	Description
ap wifi-uplink-profile <profile-name>	Name of this instance of the profile. The name must be 1-63 characters.
allowed band {a g all}	The radio band(s) on which the Wi-Fi uplink is used. Select one of the following options: <ul style="list-style-type: none">■ a: 802.11a band only (5 GHz)■ g: 802.11g band only (2.4 GHz)■ all: Both 802.11a and 802.11g bands (5 GHz and 2.4 GHz) all
bssid <bssid>	Name of the required BSSID to which the client is associated.
clone	Copies data from another Wi-Fi uplink profile.
essid <essid>	Name of the required ESSID to which the client is associated.
no	Negates any configured parameter.
opmode	Name of the data encryption mode. Select one of the following modes: <ul style="list-style-type: none">■ opensystem—No authentication or encryption.■ personal—A wildcard mode that matches several PSK mode key management suites and cipher suites,

Parameter	Description
	<p>including WPA-PSK-TKIP, WPA-PSK-AES, WPA2-PSK-TKIP and WPA2-PSK-AES.</p> <ul style="list-style-type: none"> ■ static-wep—WEP with static keys. <p>NOTE: The static-wep opmode is no longer supported from ArubaOS 8.11.0.0 onwards.</p> <p>opensystem</p>
wepkey1 <wepkey1>	<p>The first static WEP key associated with the key index. Can be 10 or 26 hex characters in length.</p> <p>NOTE: The wepkey1 <wepkey1> parameter is no longer supported from ArubaOS 8.11.0.0 onwards.</p>
wepkey2 <wepkey2>	<p>The second static WEP key associated with the key index. Can be 10 or 26 hex characters in length.</p> <p>NOTE: The wepkey2 <wepkey2> parameter is no longer supported from ArubaOS 8.11.0.0 onwards.</p>
wepkey3 <wepkey3>	<p>The third static WEP key associated with the key index. Can be 10 or 26 hex characters in length.</p> <p>NOTE: The wepkey3 <wepkey3> parameter is no longer supported from ArubaOS 8.11.0.0 onwards.</p>
wepkey4 <wepkey4>	<p>The fourth static WEP key associated with the key index. Can be 10 or 26 hex characters in length.</p> <p>NOTE: The wepkey4 <wepkey4> parameter is no longer supported from ArubaOS 8.11.0.0 onwards.</p>
weptxkey <weptxkey>	<p>The key index to specify which static WEP key is to be used. Can be 1, 2, 3, or 4.</p> <p>1</p> <p>NOTE: The weptxkey <weptxkey> parameter is no longer supported from ArubaOS 8.11.0.0 onwards.</p>
wpa-hexkey <wpa-hexkey>	<p>The WPA Pre-Shared Key (PSK). This key must be of 64 hexadecimal characters.</p>
wpa-passphrase <wpa-passphrase>	<p>The WPA password that generates the PSK. The passphrase must be between 8–63 characters, inclusive</p>

Example

The following commands create a Wi-Fi uplink profile:

```
(host) [mynode] (config) # ap wifi-uplink-profile test-uplink
(host) [mynode] (WiFi uplink profile "test-uplink") # essid uplink-new
(host) [mynode] (WiFi uplink profile "test-uplink") # wpa-passphrase *****
(host) [mynode] (WiFi uplink profile "test-uplink") # opmode personal
(host) [mynode] (WiFi uplink profile "test-uplink") # exit
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The following parameters were deprecated: <ul style="list-style-type: none"> ▪ static-wep under opmode ▪ wepkey1 <wepkey1> ▪ wepkey2 <wepkey2> ▪ wepkey3 <wepkey3> ▪ wepkey4 <wepkey4> ▪ weptxkey <weptxkey>
ArubaOS 8.5.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters.	Config mode on Mobility Conductor.

ap wipe out flash

```
ap wipe out flash
  ap-name <ap-name>
  ip-addr <ip-addr>
```

Description

Overwrite the entire AP compact flash, destroying its contents (including the current image file). Use this command only under the supervision of Aruba technical support. If you delete the current image in the AP's flash memory, the AP will not function until you reload another image.

Parameter	Description
ap-name	Wipe out the flash of the AP with the specified name.
ip-addr	Wipe out the flash of the AP with the specified IP address.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

ap wired-ap-profile

```
ap wired-ap-profile {default | <profile-name>}
  broadcast
  clone {default | <source> }
  forward-mode {bridge|split-tunnel|tunnel}
  no
  switchport {access vlan <vlan> | mode {access|trunk} | trunk {allowed vlan <vlan-
list>| add <vlan-list> | except <vlan-list> | remove <vlan-list>}} | {native vlan
<vlan>}
  trusted
  wired-ap-enable
  wired-ap-mode {normal|daisy-chain}
```

Description

This command configures a wired AP profile. This command is only applicable to Aruba APs that support a second Ethernet port. The wired AP profile configures the second Ethernet port (enet1) on the AP.

For mesh deployments, this command is applicable to all Aruba APs configured as mesh nodes. If you are using mesh to join multiple Ethernet LANs, configure and enable bridging on the mesh point Ethernet port.

Mesh nodes only support bridge mode and tunnel mode on their wired ports (enet0 or enet1). Split tunnel mode is not supported.

Use the bridge mode to configure bridging on the mesh point Ethernet port. Use tunnel mode to configure secure jack operation on the mesh node Ethernet port.

When configuring the Ethernet ports on APs with multiple Ethernet ports, note the following requirements:

- configured as a mesh portal, connect enet0 to the managed device to obtain an IP address. The wired AP profile controls enet1. Only enet1 supports secure jack operation.
- configured as a mesh point, the same wired AP profile will control both enet0 and enet1.

Parameter	Description
ap wired-ap-profile <profile-name>	Name of this instance of the profile. The name must be 1-63 characters.
broadcast	Forward broadcast traffic to this tunnel.
clone <source>	Name of an existing wired AP profile from which parameter values are copied.

Parameter	Description
forward-mode	<p>In this default forwarding mode, the AP handles all 802.11 association requests and responses, but sends all 802.11 data packets, action frames and EAPOL frames over a GRE tunnel to the managed device for processing. The managed device removes or adds the GRE headers, decrypts or encrypts 802.11 frames and applies firewall rules to the user traffic as usual. This parameter controls whether data is tunneled to the managed device using generic routing encapsulation (GRE), bridged into the local Ethernet LAN (for remote APs), or a combination thereof depending on the destination (corporate traffic goes to the managed device, and Internet access remains local). All forwarding modes support band steering, TSPEC or TCLAS enforcement, 802.11k and station blacklisting/denylisting.</p>
bridge	<p>802.11 frames are bridged into the local Ethernet LAN. When a remote AP or campus AP is in bridge mode, the AP handles all 802.11 association requests and responses, encryption or decryption processes, and firewall enforcement. The 802.11e and 802.11k action frames are also processed by the AP, which then sends out responses as needed.</p> <p>An AP in bridge mode supports 802.1X and MAC authentication types.</p> <p>Virtual APs in bridge mode using static WEP should use key slots 2-4 on the managed device. Key slot 1 should only be used with Virtual APs in tunnel mode.</p>
split-tunnel	<p>802.11 frames are either tunneled or bridged, depending on the destination (corporate traffic goes to the managed device, and Internet access remains local). An AP in split-tunnel mode supports only the 802.1X authentication type.</p> <p>An AP in split-tunnel forwarding mode handles all 802.11 association requests and responses, encryption or decryption, and firewall enforcement. The 802.11e and 802.11k action frames are also processed by the AP, which then sends out responses as needed.</p> <p>Virtual APs in split-tunnel mode using static WEP should use key slots 2-4 on the managed device. Key slot 1 should only be used with Virtual APs in tunnel mode.</p>
tunnel	<p>In this default forwarding mode, the AP handles all 802.11 association requests and responses, but sends all 802.11 data packets, action frames, and EAPOL frames over a GRE tunnel to the managed device for processing. The managed device removes or adds the GRE headers, decrypts or encrypts 802.11 frames and applies firewall rules to the user traffic as usual.</p>
no	Negates any configured parameter.
switchport	Configures the switching mode characteristics for the port.
access vlan <vlan>	The VLAN to which the port belongs. The default is VLAN 1.

Parameter	Description
<code>mode {access trunk}</code>	The mode for the port, either access or trunk mode. The default is access mode.
<code>trunk allowed vlan {add <vlan-list> except <vlan-list> remove <vlan-list> <vlan-list></code>	Allows multiple VLANs on the port interface. You must define this parameter using VLAN IDs or VLAN names. VLAN IDs and VLAN names cannot be listed together.
<code>trunk native vlan <vlan></code>	The native VLAN for the port (frames on the native VLAN are not tagged with 802.1q tags).
<code>trusted</code>	Sets port as either trusted or untrusted. The default setting is untrusted.
<code>wired-ap-enable</code>	Enables the wired AP. The wired AP is disabled by default.
<code>wired-ap-mode</code>	Enables the wired AP mode. The wired AP mode can be set to daisy-chain or normal modes.
<code>daisy-chain</code>	Enables daisy-chain mode. In this mode, the port works on trusted bridge mode and it retains the previous wired port configuration even when the controller is disconnected.
<code>normal</code>	Enables the wired AP in normal mode.

Example

The following command configures the enet1 port on a multi-port AP as a trunk port:

```
(host) [mynode] (config) #ap wired-ap-profile wiredap1
(host) [mynode] (Wired AP profile "wiredap1") #switchport mode trunk
(host) [mynode] (Wired AP profile "wiredap1") #switchport trunk allowed 4,5
```

Command History

Release	Modification
ArubaOS 8.4.0.0	The <code>wired-ap-mode</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

ap wired-port-profile

```
ap wired-port-profile {default | <profile-name>}
  aaa-profile {default | <profile-name>}
  authentication-timeout <timeout>
  auto-recovery-enable
  auto-recovery-interval <auto-recovery-interval>
  bridge-role
  broadcast-threshold <broadcast-threshold>
  clone {default | <source>}
  enet-link-profile <profile-name>
  lldp-profile {default | <profile-name>}
  loop-detection-interval <loop-detection-interval>
  loop-protect-enable
  no
  portfast
  portfast-trunk
  rap-backup
  shutdown
  spanning-tree
  storm-control-broadcast
  storm-control-broadcast-threshold
  wired-ap-profile <profile-name>
```

Description

This command configures a wired port profile. This command is only applicable to APs with Ethernet ports. Issue this command to enable or disable the wired port, define an AAA profile for wired port devices, and associate the port with an ethernet link profile that defines its speed and duplex values.

Parameter	Description
ap wired-port-profile <profile-name>	Name of this instance of the profile. The name must be 1-63 characters.
aaa-profile <profile-name>	Name of a AAA profile to be used by devices connecting to the wired port of the AP.
authentication-timeout <timeout>	Authentication timeout value, in seconds, for devices connecting the wired port of the AP. 1-65535 5

Parameter	Description
auto-recovery-enable	Enables automatic recovery of the port in the AP that is shut down because of loop protection. After the automatic recovery, if the loop re-occurs, then the port is shutdown again Disabled
auto-recovery-interval <auto-recovery-interval>	Specify the time, in seconds, to automatically recover the port in the AP that is shut down because of loop protection. 30-43200 300
bridge-role <role>	Role that is assigned to a user if split-tunnel authentication fails.
broadcast-threshold <broadcast-threshold>	Set the storm control threshold in packets per second. 1-1000000 2000
clone <source>	Create a new AP wired port profile based upon the values of an existing profile.
enet-link-profile <profile-name>	Specify an Ethernet link profile to be used by devices associated with this wired port profile. The Ethernet link profile defines the duplex value and speed to be used by the port.
lldp-profile <profile-name>	Specify an LLDP profile to be used by devices associated with this wired port profile. The LLDP profile specifies the type-length-value (TLV) elements to be sent in LLDP PDUs.
loop-detection-interval <loop-detection-interval>	Specify the time, in seconds, to send loop detection packets on the ports of an AP. 1-10 2
loop-protect-enable	Enables loop protection on the ports of an AP.

Parameter	Description
	Disabled
no	Negates any defined parameter
portfast	Enables portfast for AP wired ports. Spanning tree must be enabled before this command can be used.
portfast-trunk	Spanning tree must be enabled before this command can be used.
rap-backup	Use the <code>rap-backup</code> parameter to use the wired port on a Remote AP for local connectivity and troubleshooting when the AP cannot reach the managed device. If the AP is not connected to the managed device, no firewall policies will be applied when this option is enabled. (The AAA profile will be applied when the AP is connected to managed device).
shutdown	Disable the wired AP port.
spanning-tree	Enables the spanning-tree protocol.
storm-control-broadcast	Enables the broadcast storm control. When this parameter is enabled, if the AP detects a loop on one of its Ethernet port, it shuts down the Ethernet port. This prevents the AP from receiving or sending any frames.
storm-control-broadcast-threshold	Specify the broadcast packets per second on each Ethernet port of an AP before the Ethernet port is shut down. 2000
wired-ap-profile <profile-name>	Name of a wired AP profile to be used by devices connecting the wired port of the AP. The wired AP profile defines the forwarding mode and switchport values used by the port.

Example

The following command defines a AAA profile for wired port devices:

```
(host) [mynode] (config) #ap wired-port-profile wiredport1
(host) [mynode] (AP wired port profile"wiredport1") #aaa-profile default-open
(host) [mynode] (AP wired port profile"wiredport1") #authentication-timeout
30
(host) [mynode] (AP wired port profile"wiredport1") #wired-ap-profile
wiredapl
```

Command History

ap zeroize-tpm-keys

```
ap zeroize-tpm-keys {ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr>}
```

Description

This command is used to erase the TPM content and render an AP permanently inoperable.

Parameter	Description
ap-name <ap-name>	Name of the AP.
ip-addr <ip-addr>	IP address of the AP.
ip6-addr <ip6-addr>	IPv6 address of the AP.

Example

Execute the following command to erase the TPM content and render an AP permanently inoperable.

```
(host) [mynode] (config) #ap zeroize-tpm-keys 192.168.2.4
You are about to execute a command which will make the AP inoperable and
void the RMA.
Are you sure you want to proceed? [y/n]: y
TPM keys have been zeroized. Please reboot the AP.
```

arci-set-mon-request-timeout

```
arci-set-mon-request-timeout <time>
```

Description

This command sets MON response timeout value for webUI request.

Parameter	Description
<time>	Specify MON response timeout value in seconds for webUI request. 25 seconds

Example

The following command sets MON response timeout to 20 seconds for webUI request.

```
(host) [mynode]arci-set-mon-request-timeout 20
```

arm cellular-move-sta

```
arm cellular-move-sta <mac> <est-tput>
```

Description

This command triggers a cellular handoff assist.

Parameter	Description
<mac>	MAC address of STA to kick off from wifi.
<est-tput>	Estimated throughput value(kbps).

Example

The following command triggers a cellular handoff assist.

```
(host)[mynode]arm cellular-move-sta 00:05:4e:50:14:aa 23
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

arm move-sta

```
arm move-sta <client-mac> <newbssid>
```

Description

This command moves a client station to another BSSID.

Parameter	Description
<mac>	MAC address of the client to be moved to another BSSID
<newbssid>	BSSID of the AP to which the client should associate.

Example

The following command moves a client with the MAC address **00:0B:86:01:7A:C0** to the BSSID **00:1C:B3:09:85:15**:

```
(host) [mynode] (config) #arm move-sta 00:0B:86:01:7A:C0 00:1C:B3:09:85:15
```

arp

```
arp <ipaddr> <macaddr>
```

Description

This command adds a static Address Resolution Protocol (ARP) entry. If the IP address does not belong to a valid IP subnetwork, the ARP entry is not added. If the IP interface that defines the subnetwork for the static ARP entry is deleted, you will be unable to use the arp command to overwrite the entry's current values; use the no arp command to negate the entry and then enter a new arp command.

Parameter	Description
<ipaddr>	IP address of the device to be added.
<macaddr>	Hardware address of the device to be added, in the format xx:xx:xx:xx:xx:xx.

Example

The following command configures an ARP entry:

```
(host) [node] (config) #arp 10.152.23.237 00:0B:86:01:7A:C0
```

audit-trail

audit-trail [all]

Description

This command enables an audit trail. By default, audit trail is enabled for all commands in configuration mode. Use the `show audit-trail` command to display the content of the audit trail.

Parameter	Description
all	Enables audit trail for all commands, including enable mode commands. The <code>audit-trail</code> command without this option enables audit trail for all commands in configuration mode.

Example

The following command enables an audit trail:

```
(host) [mynode] (config) #audit-trail
```

Related Commands

banner

```
banner
  enforce accept
  motd <delimiter> <textString>
```

Description

This command defines a text banner to be displayed at the login prompt when a user accesses Mobility Conductor. The banner you define is displayed at the login prompt for Mobility Conductor. The banner is specific to the Mobility Conductor on which you configure it. The WebUI displays the configured banner at its login prompt, but you cannot use the WebUI to configure the banner.

The delimiter is a single character that indicates the beginning and the end of the text string in the banner. Select a delimiter that is not used in the text string you define, because the Mobility Conductor ends the banner when it sees the delimiter character repeated.

There are two ways of configuring the banner message:

- Enter a space between the delimiter and the beginning of the text string. The text can include any character except a quotation mark (""). Use quotation marks to enclose your text if you are including spaces (spaces are not recognized unless your text string is enclosed in quotation marks; without quotation marks, the text is truncated at the first space). You can also use the delimiter character within quotation marks.
- Press the **Enter** key after the delimiter to be placed into a mode where you can simply enter the banner text in lines of up to 255 characters, including spaces. Quotation marks are ignored.

Parameter	Description
<code>enforce-accept</code>	Enforces the user to accept the content added in the banner before logging in.
<code>motd</code>	Enter a message, to be displayed as a banner.
<code><delimiter></code>	Indicates the beginning and end of the banner text.
<code><textString></code>	The text you want displayed. up to 1023 characters

Example

The following example configures a banner by enclosing the text within quotation marks:

```
(host) [mynode] (config) #banner motd * "Welcome to my controller. This controller is in the production network, so please do not save configuration changes. Zach Jennings is awesome. Maintenance will be performed at 7:30 PM, so please log off before 7:00 PM."*
```

The following example configures a banner by pressing the **Enter** key after the delimiter:

```
(host) [mynode] (config) #banner motd *
Enter TEXT message [maximum of 1023 characters].
Each line in the banner message should not exceed 255 characters.
End with the character '*'.

Welcome to my controller. This controller is in the production network, so please
do not save configuration changes. Zach Jennings is awesome. Maintenance will be
performed at 7:30 PM, so please log off before 7:00 PM.*
```

The banner display is as follows:

```
Welcome to my controller. This controller is in the production network, so please
do not save configuration changes. Zach Jennings is awesome. Maintenance will be
performed at 7:30 PM, so please log off before 7:00 PM.
```

Command History

Release	Modification
ArubaOS 8.4.0.0	The <code>enforce-accept</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

banner via

```
banner via <delimiter> <textstring>
```

Description

This command defines a login banner for Virtual Intranet Access (VIA) users. The banner you define is displayed when a user accesses VIA. The WebUI displays the configured banner at its login prompt, but you cannot use the WebUI to configure the banner.

The delimiter is a single character that indicates the beginning and the end of the text string in the banner. Select a delimiter that is not used in the text string you define.

There are two ways of configuring the banner message:

- Enter a space between the delimiter and the beginning of the text string. The text can include any character except a quotation mark ("). Use quotation marks to enclose your text if you are including spaces (spaces are not recognized unless your text string is enclosed in quotation marks; without quotation marks, the text is truncated at the first space). You can also use the delimiter character within quotation marks.

- Press the **Enter** key after the delimiter to be placed into a mode where you can simply enter the banner text in lines of up to 255 characters, including spaces. Quotation marks are ignored.

Parameter	Description
<delimiter>	Indicates the beginning and end of the banner text.
<textstring>	The text you want displayed. up to 1023 characters

Example

The following example configures a banner by enclosing the text within quotation marks:

```
(host) [mynode] (config) #banner via * "Welcome"*
```

The following example configures a banner by pressing the **Enter** key after the delimiter:

```
(host) [mynode] (config) #banner via *  
Enter TEXT message [maximum of 1023 characters].  
Each line in the banner message should not exceed 255 characters.  
End with the character '*'.  
  
Welcome*
```

Command History

blmgr

```
blmgr
  trace-level
    category {all | cli | stm | syslog | utild}
      loglevel {alert | critical | debug | emergency | error | info | notice |
        warn }
```

Description

This command configures client denylist manager.

Parameter	Description
trace-level	Set parameters for debug tracing in client denylist manager.
category	Specify one of the following trace category to enable or disable: <ul style="list-style-type: none">■ all: Traces all categories■ cli: Traces in the category of CLI■ stm: Traces in the category of STM■ syslog: Traces in the category of syslog■ utild: Traces in the category of UTILD
loglevel	Specify one of the following log level of syslogs to be included in the trace: <ul style="list-style-type: none">■ alert: Trace all logs equal to or higher than LOG_ALERT.■ critical: Trace all logs equal to or higher than LOG_CRIT■ debug: Trace all logs equal to or higher than LOG_DEBUG.■ emergency: Trace all logs equal to or higher than LOG_

Parameter	Description
	EMERG. ■ error : Trace all logs equal to or higher than LOG_ERR. ■ info : Trace all logs equal to or higher than LOG_INFO . ■ notice : Trace all logs equal to or higher than LOG_NOTICE. ■ warn : Trace all logs equal to or higher than LOG_WARN .

Example

The following example enables traces in the cli category and traces all logs equal to or higher than error log.

```
(host) [mynode] (config) #blmgr trace-level category cli loglevel error
```

iotcfg | set-attr <azure-log-level> <br-loglvl> <tag-logging> <ws-connect> <ws-
loglvl>}
```

Description

This command configures the Bluetooth Low Energy (BLE) relay on devices.

Parameter	Description
<code>export-ap-ble-all-beacon-info</code>	Export AP's BLE radio all Beacons parameters to a csv file.
<code>export-ap-ble-custom-beacon-info</code>	Export AP's BLE radio Custom Beacon parameters to a csv file.
<code>export-ap-ble-ibeacon-info</code>	Exports AP's BLE radio iBeacon parameters to a CSV file.
<code>send_sync_iotcfg</code>	Sends synchronized IoT configurations to the APs.
<code>set-attr</code>	Sets the attribute value.
<code>azure-log-level <azure-log-level></code>	Set one of the following azure log level for debug: <ul style="list-style-type: none">▪ none▪ error▪ info▪ trace▪ all
<code>br-loglvl <br-loglvl></code>	Process debug log for one of the following: <ul style="list-style-type: none">▪ level bitmap (AP-Transport-Profile (0x1)▪ APB Info (0x2)▪ CLI (0x4)▪ Beacon Mgmt (0x8)▪ Asset Tracking (0x10)▪ Telemetry WS (0x20)▪ Telemetry HTTPS (0x40)▪ ZF (0x80)▪ SB API(0x100)▪ WSS (0x200)▪ AZURE(0x800))
<code>tag-logging <tag-logging></code>	Initiates or terminates the tag report logging. This action is completed using binary numbers, for example 1: initiate, 0: terminate.

Parameter	Description
<code>ws-connect <ws-connect></code>	Initiates or terminates the web-socket connection. This action is completed using binary numbers, for example, 1: initiate, 0: terminate.
<code>ws-loglvl <ws-loglvl></code>	Provides the log levels to debug a web-socket connection.

Example

The following command exports the AP's BLE iBeacon information into a CSV file:

```
(host) [mynode] #ble_relay export_ap_ble_ibeacon_info
ble_info.txt file ready to be copied out
=====
```

Command History

Release	Modification
ArubaOS 8.4.0.0	The <code>export-ap-ble-ibeacon-info</code> parameter was introduced.
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on the Mobility Conductor.

ble_relay set-attr

```
ble_relay set-attr {azure-log-level <azure-log-level> | br-loglvl <br-loglvl> |  
tag-logging <tag-logging> | ws-connect <ws-connect> | ws-loglvl <ws-loglvl>}
```

Description

This command configures the attribute values of Bluetooth Low Energy (BLE) relay.

Parameter	Description
azure-log-level <azure-log-level>	Set one of the following azure log level for debug: <ul style="list-style-type: none">▪ none▪ error▪ info▪ trace▪ all
br-loglvl <br-loglvl>	Process debug log for one of the following: <ul style="list-style-type: none">▪ level bitmap (AP-Transport-Profile (0x1)▪ APB Info (0x2)▪ CLI (0x4)▪ Beacon Mgmt (0x8)▪ Asset Tracking (0x10)▪ Telemetry WS (0x20)▪ Telemetry HTTPS (0x40)▪ ZF (0x80)▪ SB API(0x100)▪ WSS (0x200)▪ AZURE(0x800)
tag-logging <tag-logging>	Initiates or terminates the tag report logging. Enter one of the following values: <ul style="list-style-type: none">▪ 1: initiate▪ 0: terminate
ws-connect <ws-connect>	Initiates or terminates the WebSocket connection.
ws-loglvl <ws-loglvl>	Enter the log level to debug the WebSocket connection.

Command History

Release	Modification
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on the Mobility Conductor.

ble service-profile

```
ble service-profile <profile-name> {advertisement-format ibeacon|clone
<source>|include-ap-group <include-ap-group>|major <major-range>|minor <minor-
range>|no|radio-instance {all|external|internal}|uuid <uuid>}
```

Description

This command configures a Bluetooth Low Energy (BLE) service profile.

Parameter	Description
<profile-name>	Name of the BLE service profile.
advertisement-format ibeacon	Advertising behavior. Only iBeacon is supported.
advertisement-interval	Interval for advertised beacon. Range: [100-30000 ms] and increment in multiples of 100. Default: 500ms
clone <source>	Copy data from another BLE service profile.
custom-payload	The payload for custom beacon. The length is 3-31 bytes and each byte includes 2 ASCII characters.
include-ap-group <include-ap-group>	Applies the BLE service profile to specified AP group.
major <major-range>	Major range of iBeacon in minimum-maximum format. Default value is 0-65535.
minor <minor-range>	Minor range of iBeacon in minimum-maximum format. Default value is 0-65535.
no	Negates any configured parameter.
radio-instance	IoT radio instance to use.
all	Use all IoT radio instances.
external	Use external IoT radio instance.
internal	Use internal IoT radio instance.
uuid <uuid>	iBeacon UUID in hexadecimal format of predefined length. Example: 4152554E-F99B-4A3B-86D0-947070693A78

Example

The following command exports the AP's BLE iBeacon information into a CSV file:

```
(host) [mynode] (config) #ble service-profile default
(host) [mynode] (BLE service profile "default") #advertisement-format
ibeacon
(host) [mynode] (BLE service profile "default") #include-ap-group lobby
(host) [mynode] (BLE service profile "default") #major 0-65535
(host) [mynode] (BLE service profile "default") #minor 0-65535
(host) [mynode] (BLE service profile "default") #radio-instance all
(host) [mynode] (BLE service profile "default") #uuid 4152554E-F99B-4A3B-
86D0-947070693A78
```

Related Commands

Command	Description
show ble service-profile	Shows the BLE service profile.

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on the Mobility Conductor.

boot

```
boot
  cf-test [fast|read-only|read-write]
  system partition <partition_id>
  verbose
```

Description

This command configures the boot options for the controller.

Parameter	Description
cf-test	Sets the type of compact flash test to run when booting the controller.
fast	Performs a fast test, which does not include media testing.
read-only	Performs a read-only media test.
read-write	Performs a read-write media test.
system partition {0 1}	Enter system partition followed by the partition number (0 or 1) that you want the controller to use during the next boot (login) of the controller. NOTE: A controller reload is required before the new boot partition takes effect.
verbose	Prints extra debugging information at boot.

Example

The following command uses system partition 1 the next time the controller boots:

```
(host) [mynode] #boot system partition 1
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config and Enable mode on Mobility Conductor.

branch-gateway

```
branch-gateway
  peer <IP address>
  interface vlan <vlanId>
```

Description

This command configures Branch Gateway.

Parameter	Description
<code>peer <IP address></code>	Specify IP address of transit vlan in peer gateway.
<code>interface vlan <vlanId></code>	Specify VLAN ID of the transit interface to use for sending peer traffic.

Example

The following example configures a banner by enclosing the text within quotation marks:

```
(host) [mynode] (config) #branch-gateway peer 12.3.4.5 interface vlan 2
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Config mode on Mobility Conductor.

branch-uplink-pool

```
branch-uplink-pool <branch_pool_name> <branch_pool_start_address> <branch_pool_end_address>
```

Description

This command is used to configure branch uplink IP Pool for branch deployment. Uplink pool is configured on the VPNC's to handle duplicate IP addresses scenario on the branches.

Parameter	Description
<branch_pool_name>	Name of the pool.
<branch_pool_start_address>	Starting IP address for the pool.
<branch_pool_end_address>	Ending IP address for the pool.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

bulkedit import csv

```
bulkedit import csv <csv-name>
```

Description

Use the `bulkedit import csv` command to import data from a .csv file.

Parameter	Description
<code>bulkedit import csv</code>	Imports data from a .csv file.
<code><csv-name></code>	Name of the .csv file.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config modes on the managed device or the Mobility Conductor.

bulkedit export devices

bulkedit export devices

Description

Use the `bulkedit export devices` command to export data to a .csv file.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config modes on the managed device or the Mobility Conductor.

ca-bundle

```
ca-bundle
  update
    connect-timeout <timeout value>
    max-time <max-time value>
    download_url <url>
  reset
```

Description

This command upgrades/ resets the trusted CA certificates.

Parameter	Description
update	Upgrades the trusted CA certificates of managed devices.
connect-timeout<timeout value>	Time allowed, in seconds, for the managed device to connect to the server Range: 1-3600 Default: 120
max-time <max-time value>	Maximum time allowed, in seconds, for the certificates to upgrade. Range: 1-3600 Default: 120
download_url <url>	(Optional) CA certificates will be downloaded from the specified URL. If URL is not mentioned, the certificates will be downloaded from Activate. NOTE: The URL should begin with either http or https.
reset	Resets certificates to the factory default image.

Example

The following command upgrades the trusted CA certificates:

```
(host) [mynode] (config) #ca-bundle update connect-timeout 60
(host) (mynode) (config) #ca-bundle update max-time 120
```

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on managed devices.

capacity-license

```
capacity-license
enable
```

Description

This command configures capacity-license feature .

Parameter	Description
enable	Enable capacity-license feature.

Example

```
(host) [mynode] (config) #capacity-license enable
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command requires the PEFNG license.	Configure mode on Mobility Conductor.

ccm-debug

```
ccm-debug
  config-dump {disable | enable}
  config-rollback node <node-path> config-id <cfg-id>
  full-config-sync
  verify-config-sync
```

Description

Use the `ccm-debug config-rollback` command to roll back the configuration of a node to the previous version. Use this command to request a full configuration sync.

Parameter	Description
<code>config-dump</code>	Configure config dump message after write memory command. <ul style="list-style-type: none">▪ disable : Disables config dump after write memory command.▪ enable : Enables config dump after write memory command.
<code>config-rollback</code>	Rolls back to the previous configuration.
<code>node <node></code>	Specifies the configuration node.
<code>config-id <cfg-id></code>	Specifies the configuration ID (full path name of the config node) to roll back to.
<code>full-config-sync</code>	Request for a full config sync.
<code>verify-config-sync <node-path></code>	Verify if connected managed devices and Standby configurations are in sync.
<code>app-config</code>	Compare with application's running configuration.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable and Config mode on the managed device or the Mobility Conductor.

cd

cd <node-path>

Description

This command changes the current configuration node to the specified node. The desired node is specified by the node-path, which can be an absolute path from the root node or relative path from the current node. Use this command to view the list of all nodes in the configuration hierarchy.

Parameter	Description
<node-path>	Path of the configuration node.

Example

The following command changes the current node-path (**/mm/mynode**) to **/md**:

```
(host) [mynode] #cd /md
(host) [md] #
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command requires the PEFNG license.	Config mode on Mobility Conductor.

cfgm

```
cfgm {set config-chunk <size>|set heartbeat <time>|set timeout <time>|set  
vpnconnect_retry <retry num>}
```

Description

This command enables the configuration module on a Mobility Conductor or a managed device.

Parameter	Description
set config-chunk	Maximum packet size, in Kilobytes, that is sent every second to a managed device whenever a configuration is sent to that node. If the connection between the Mobility Conductor and managed device is slow or uneven, you can lower the size to reduce the amount of data that must be retransmitted. If the connection is very fast and stable, you can increase the size to make the transmission more efficient. 1-100 10 Kbytes
set heartbeat	Interval, in seconds, at which heartbeats are sent. You can increase the interval to reduce traffic load. 10-300 10 seconds
set timeout	Time, in seconds, of socket Rx inactivity before reconnecting with Mobility Conductor. 20-200 120 seconds
set vpnconnect_retry	VPN pre-connect packet retry heartbeat intervals . 3

Example

The following command sets the maximum packet size as 20 KB per second whenever a configuration is sent to the managed device:

```
(host) [mm] (config) #cfgm set config-chunk 20
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>set timeout</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

change-config-node

change-config-node <node-path>

Description

This command changes the current CLI node context to the specified node. The desired node is specified by the node-path, which can be an absolute path from the root node or relative path from the current node. Use this command to view the list of all nodes in the configuration hierarchy.

Parameter	Description
<node-path>	Path of the configuration node.

Example

The following command changes the current node-path (**/mm/mynode**) to **/md**:

```
(host) [mynode] #change-config-node /md
(host) [md] #
```

Related Commands

Command	Description
cd	Changes the working node to the specified path.

Description

This command clears various user-configured values from your running configuration. This command clears the specified parameters of their current values.

Parameter	Description
aaa	Clear all values associated with authentication profile.
auth-survivability-cache	Clear all auth survivability cached data. Parameters: <ul style="list-style-type: none"> ▪ <code>all</code>—Clear all entries in the auth survivability cache. ▪ <code>station</code>—Clear an entry in the auth survivability cache for station.
authentication-server	Provide authentication server details to clear values specific to an authentication server or all authentication server. Parameters: <ul style="list-style-type: none"> ▪ <code>all</code>—Clear all server statistics. ▪ <code>internal</code>—Clear Internal server statistics. ▪ <code>ldap</code>—Clear LDAP server statistics. ▪ <code>radius</code>—Clear RADIUS server statistics. ▪ <code>tacacs</code>—Clear TACACS server statistics.
device-id-cache	Clear all device ID cache. Parameters: <ul style="list-style-type: none"> ▪ <code>all</code>—Clear all entries in the device ID cache.

Parameter	Description
	<ul style="list-style-type: none"> ▪ <code>mac</code>—Clear entries in the device ID cache for MAC address.
<code>load-balance statistics</code>	Clear load balance statistics. Parameters: <ul style="list-style-type: none"> ▪ <code>server group</code>—Clear load balance statistics of a server group.
<code>multiple-server-accounting statistics</code>	Clear multiple server accounting statistics. Parameters: <ul style="list-style-type: none"> ▪ <code>all</code>—Clear for all server groups. ▪ <code>server-group</code>—Clear multiple server accounting statistics for a server group.
<code>state</code>	Clear internal status of authentication modules. Parameters: <ul style="list-style-type: none"> ▪ <code>configuration</code>—Clear all configured objects. ▪ <code>debug-statistics</code>—Clear debug statistics. ▪ <code>messages</code>—Clear authentication messages that were sent and received.
<code>acl</code>	Clear ACL statistics.
<code>hits</code>	Clear ACL hit statistics.
<code>acl-debug</code>	Debug ACL hit statistics.
<code>airgroup</code>	Clear AirGroup statistics and user entries from the user table.
<code>cli-policy all</code>	Clears AirGroup policies except ClearPass Policy Manager policies.
<code>server</code>	Clears AirGroup servers.
<code>statistics</code>	<ul style="list-style-type: none"> ▪ blocked-queries—Clears the statistics of service IDs which were queried but not available in the AirGroup service table.

Parameter	Description
	<ul style="list-style-type: none"> ▪ blocked-service-id—Clears the statistics for the list of blocked services. ▪ cppm-entries—Clears the statistics that are displayed for show airgroup cppm entries command. ▪ internal-state—Clears internal state statistics of mDNS module. ▪ multi-controller—Clears the statistics maintained for multi-controller message exchanges. ▪ query—Clears statistics maintained in the user and server table. ▪ service—Clears statistics maintained in the AirGroup service table.
user	<ul style="list-style-type: none"> ▪ Mac Address—Clears the AirGroup server Mac addresses. ▪ dlna—Clears the AirGroup DLNA users. ▪ mdns—Clears the AirGroup mDNS users. ▪ all—Removes the current AirGroup user entries from the user table.
ap	Clear all AP related information.
arm bandwidth-management	Clears AP bandwidth management table counters. An AP can be specified by ap-name, BSSID, IPv4 address, or IPv6 address.
arm client-match	<ul style="list-style-type: none"> ▪ rules file-name <file-name> — Clears an imported file of ClientMatch rules. ▪ summary—Clears the ClientMatch summary information ▪ unsupported—Clears the MAC address of an unsteerable client or clients.

Parameter	Description
<pre>crash-info</pre>	Clears AP crash information. An AP can be specified by ap-name, IPv4 address, or IPv6 address.
<pre>debug</pre>	<ul style="list-style-type: none"> ▪ bss-dmo-stats— Clears DMO debug statistics from a specific BSSID of an AP. ▪ classification-counters—Clears classification counters. ▪ client-stats— Clears statistics from a client. ▪ dot11r {efficiency-stat}— Clears 802.11r-related stats. ▪ lacp—Clears transmitted and received packet counters displayed in the show ap debug lacp command. ▪ lldp—Clears LLDP for an AP. ▪ counters—Clears LLDP statistics. ▪ openflow— Clears openflow statistics. ▪ radio-stats— Clears aggregate radio debug statistics of an AP. ▪ sta-msg-stats—Clear AP-STM to STM message statistics.
<pre>mesh</pre>	Clear all mesh commands. <ul style="list-style-type: none"> ▪ debug—Clears debug information. ▪ counters—Clears statistics for a mesh node.
<pre>port {ap-name serial-num wired-mac} <port></pre>	Toggle the link on the specified port. <ul style="list-style-type: none"> ▪ ap-name—Clear specified port on AP with this name. ▪ serial-num—Clear specified port on AP with this serial number. ▪ wired-mac—Clear specified port on AP at this MAC address.
<pre>remote flash-config</pre>	Clears the flash configuration from a specified AP. An AP can be specified by ap-name, BSSID, IPv4 address, or IPv6 address.

Parameter	Description
arci-mon-mgmt-server	Clear management server counters
arm	Clear the following types of ARM ClientMatch information: <ul style="list-style-type: none"> client-match-summary client-match-unsteerable
arp	Clear all ARP table information. You can either clear all information or enter the IP address of the ARP entry to clear a specific value.
aruba-central	Clear Aruba Central WS Counters
ble_relay	Display ble relay status.
branch-gateway-peer	Display branch gateway peer information
counters	Clear all interface configuration values.
gigabitethernet	Clears configuration related to gigabitethernet ports.
port-channel <id>	Clears statistics related to a port-channel. Port-channel ID ranges from 0 to 7.
tunnel	Clears all tunnel configuration values on interface ports.
vrrp [ipv6]	Clears all VRRP configuration values on interface ports. Include the ipv6 parameter to clear IPv6 counters.
crypto	Clears the specified crypto information.
dp	Clears crypto latest DP packets.
ipsec sa [peer [[<ip-address>] [v6 <ipv6-address>]]]	Clears crypto IPsec state SAs for the following: <ul style="list-style-type: none"> peer—state for a peer v6—state for an ipv6 peer
isakmp sa [peer [[<source-ip>] [v6 <source-ipv6>]]]	Clears crypto isakmp state SAs for the following: <ul style="list-style-type: none"> peer—state for a peer v6—state for an ipv6 peer

Parameter	Description
stats	Clears crypto statistics.
datapath	<p>Clears all configuration values and statistics for the following datapath modules.</p> <ul style="list-style-type: none"> ▪ application {counters} ▪ bridge {counters} ▪ bwm {counters} ▪ compression {counters} ▪ cp-bwm {counters} ▪ crypto {counters} ▪ debug {performance} ▪ dma {counters} ▪ eap {counters} ▪ frame {counters} ▪ hardware {counters statistics} ▪ ip-fragment-table {ipv4 ipv6} ▪ ip-reassembly {counters} ▪ maintenance {counters} ▪ message-queue {counters} ▪ mobility {stats} ▪ network {egress ingress} ▪ papi {counters remote-device-table} ▪ route {counters} ▪ route-cache {A.B.C.D counters} ▪ route-cache-v6 {X:X:X:X} ▪ scheduler {counters} ▪ session {dpi counters} ▪ ssl {counters} ▪ station {counters} ▪ tcp {counters} ▪ tunnel {counters} ▪ user {counters} ▪ wan-hc {counters} ▪ web-cc {counters} ▪ wifi-reassembly {counters} ▪ wmm {counters}
dds	Clears Distributed Data Store statistics.
dot1x	<p>Clears all 802.1X-specific counters and supplicant statistics. Use the following parameters:</p> <ul style="list-style-type: none"> ▪ counters

Parameter	Description
	<ul style="list-style-type: none"> ▪ <code>supplicant-info</code>
<code>fault</code>	Clears all SNMP fault configuration.
<code>gap-db</code>	<p>Clears global AP database. This command is often used to clear all stale AP records. Use the following parameters:</p> <ul style="list-style-type: none"> ▪ <code>ap-name</code> ▪ <code>lms</code> ▪ <code>wired-mac</code> <p>To delete stale APs:</p> <ol style="list-style-type: none"> 1. Issue the <code>clear gap-db stale-ap ap-name <ap-name> lms lms-ip <lms-ip></code> command to delete a stale entry on a particular managed device. 2. Issue the <code>clear gap-db ap-name <ap-name></code> command to delete the GAP entries for the AP on the Mobility Conductor and the current LMS of the AP. <p>NOTE: The first step will delete stale entries individually from the old managed devices and the second step will remove stale entries for the Mobility Conductor and the current LMS.</p>
<code>gsm</code>	Clear GSM statistics.
<code>iap branch-key</code>	Clear IAP branch key.
<code>iap statistics</code>	Clear IAP statistics.
<code>iap subnet-stats</code>	Clear statistics of IAP subnet.
<code>ifmap</code>	Clear IF-MAP connection.
<code>ip</code>	<p>Clears IP information from DHCP bindings, IGMP groups and IP mobility configuration. Use the following parameters:</p> <ul style="list-style-type: none"> ▪ <code>dhcp</code>

Parameter	Description
	<p>Starting from ArubaOS 8.8.0.0, issue the <code>clear ip dhcp binding ip-address <ip-address></code> command to clear DHCP bindings for a specific IP address.</p> <ul style="list-style-type: none"> ▪ <code>igmp {cluster group mobility-group stats-counters}</code> ▪ <code>mobile {host multicast-vlan-table traffic trail}</code> ▪ <code>probe {stats}</code>
ipc statistics	<p>Clears all inter process communication statistics. Use the following parameters:</p> <ul style="list-style-type: none"> ▪ <code>app-ap</code> ▪ <code>app-id</code> ▪ <code>app-name</code>
app-ap	<p>Clears the statistics related to the following AP commands:</p> <ul style="list-style-type: none"> ▪ <code>am</code> ▪ <code>ofald</code> ▪ <code>sapd</code> ▪ <code>stm</code>
app-id	<p>Clears the statistics related to an application id.</p>
app-name	<p>Clears statistics application name related statistics:</p> <ul style="list-style-type: none"> ▪ aaa ▪ ads ▪ auth-resp ▪ authmgr ▪ certmgr ▪ cfgm ▪ cluster_mgr ▪ cpsec ▪ cts ▪ dbsync ▪ dds ▪ dhcp ▪ esi

Parameter	Description
	<ul style="list-style-type: none"> ▪ extifmgr ▪ fpapps ▪ gsmmgr ▪ httpd ▪ ike ▪ ip_flow_export ▪ l2tp L2TP ▪ licensemgr ▪ mdns ▪ mobileip ▪ ntp ▪ ofa ▪ ospf ▪ phonehome ▪ pim ▪ pktfilter ▪ pptp ▪ profmgr ▪ publisher ▪ resolver ▪ sapm ▪ sapm-resp ▪ snmpt ▪ stm ▪ stm-lopri ▪ syslogd ▪ ucm ▪ userdb ▪ web_cc ▪ wms
<p>ipv6</p>	<p>Clears all IPv6 session statistics, MLD group and member information, MLD statistics, counters, and DHCPv6 binding information. Use the following parameters:</p> <ul style="list-style-type: none"> ▪ <code>datapath {session}</code> ▪ <code>counters</code> ▪ <code>dhcp {binding}</code> ▪ <code>mld {cluster <stats> group proxy-mobility-group information stats-counters}</code> ▪ <code>neighbor {all ipv6}</code>

Parameter	Description
lc-cluster bucketmap publish counters	Clears the bucketmap publish counter values for the cluster on the Cluster Leader.
gsm counters	Clear GSM counter information for that cluster.
papi counters	Clear PAPI counter information for that cluster.
vlan-probe counters	Clear vlan-probe counters for that cluster.
lldp	<p>Clears LLDP information on all the interfaces. Use the following parameters:</p> <ul style="list-style-type: none"> ■ neighbors {interface gigabitethernet fastethernet slot/module/port} ■ statistics {interface gigabitethernet fastethernet slot/module/port}
loginsession	Clears login session information for a specific login session, as identified by the session id.
master-local/conductor-local	Clears all master-local/conductor-local switch statistics.
stats	<p>Clears the statistics of local or all switches connected to the Mobility Conductor or managed devices. Use the following sub-parameters:</p> <ul style="list-style-type: none"> ■ all— Clears the statistics of all the managed devices. ■ ip {ipv4-address ipv6-address}— Clears the statistics of IPv4 address or IPv6 address of the switch. ■ local-stats— Clears the master-local/conductor-local statistics at the managed device.

Parameter	Description
master-local-entry/conductor-local-entry	Clears managed device information from the Mobility Conductor LMS list. Specify the IP address of the managed device to be removed from the Mobility Conductor active LMS list.
master-local-session/conductor-local-session	Clear and reset master-local/conductor-local TCP connection. Specify the IP address of either the Mobility Conductor or managed device.
mon-serv	<p>Clears all monitoring server statistics. Use the following parameters:</p> <ul style="list-style-type: none"> ■ ap-microboot-stats — Clears the AP micro-bootstrapping statistics. ■ message-stats — Clears the monitoring and Advanced Monitoring (AMON) message statistics. ■ microboot-stats-all — Clears all micro-bootstrapping statistics. ■ radio-microboot-stats — Clears Radio micro-bootstrapping statistics. ■ sta-microboot-stats — Clears STA micro-bootstrapping statistics. ■ vap-microboot-stats — Clears VAP micro-bootstrapping statistics.
mon-serv-fw	<p>Clears all monitoring server statistics. Use the following parameters:</p> <ul style="list-style-type: none"> ■ apprf-pool-counters — Clears AppRF Pool counters. ■ message-stats — Clears the monitoring and Advanced Monitoring (AMON) message statistics.
off-loader	Clear offloader statistics.

Parameter	Description
openflow	Clear openflow statistics.
openflow-controller	Clear openflow statistics of the controller.
pan	Clear Palo Alto Networks interface.
perf-test	Clear Iperf throughput test process.
reports	Displays Iperf throughput test reports. Use the following parameters: <ul style="list-style-type: none"> ▪ ap {ap-name ip-addr ip6-addr} — All Iperf throughput test on the access point. ▪ controller — All Iperf throughput test on the controller.
phonehome	Resets phonehome stats.
port	Clear all port statistics that includes link-event counters or all counters. Use the following parameters: <ul style="list-style-type: none"> ▪ link-event ▪ stats
port-security-error gigabitethernet	Clear all port-security-error counters. Use the following parameters: <ul style="list-style-type: none"> ▪ slot ▪ module ▪ port
process	Clear Process level operations.
fpapps	Clear information from Level7's Layer2/Layer3 module.
message-queue-stats	Clear statistics on Fpapps internal message queue operations.
task-stats	Clear statistics on Fpapps internal OS API tasks.
timer-stats	Clear statistics on Fpapps Internal Timer Module.

Parameter	Description
<code>provisioning-ap-list</code>	Clear APs from provisioning list.
<code>provisioning-params</code>	Clear provisioning parameters and reset them to the default configuration values.
<code>rap-wml</code>	Clear wired MAC lookup cache for a DB server.
<code>snmp</code>	Clear SNMP information.
<code>tunneled-node-mgr</code>	Clear tunneled node manager information.
<code>ucc</code>	Clear UCC state information.
<code>client ip <ipaddr></code>	Clear the UCC counter for a client.
<code>sessions ip <ipaddr></code>	Clear active UCC sessions based on a specific client IP address.
<code>statistics counter call {client global}</code>	Clear UCC call statistics based on particular client or system wide.
<code>update-counter</code>	Clear all update counter statistics.
<code>uplink</code>	Clear uplink manager configuration.
<code>vpdn</code>	Clear all VPDN configuration for L2TP and PPTP tunnel. Use the following parameters: <ul style="list-style-type: none"> ■ <code>tunnel l2tp id <l2tp-tunnel-id></code> ■ <code>tunnel pptp id <pptp-tunnel-id></code>
<code>web-cc</code>	Clear all web content classification information.
<code>web-cc cache <MD5-1></code>	Clear web content category URLs from the datapath cache by specifying the two MD5 values of the URL to be removed from the cache. To view all entries in the datapath, and the MD5 values for each entry, issue the command <code>show datapath web-cc</code> .

Parameter	Description
<code>web-cc stats</code>	Clear all web content classification statistics. To view current statistics information, issue the command <code>show web-cc stats</code> .
<code>web-cc md</code>	Clear all web content classification managed nodes. Use the following parameter: <ul style="list-style-type: none"> ▪ <code>stats</code> — Clears all web content classification statistics.
<code>websocket</code>	Clear Web-Socket Interface statistics.
<code>whitelist-db/ allowlist-db</code>	Clear whitelist/allowlist statistics. Use the following parameter: <ul style="list-style-type: none"> ▪ <code>cpsec-stats</code> — Clear CPsec whitelist/allowlist statistics.
<code>wms</code>	Clear all WLAN management commands. Use the following parameters: <ul style="list-style-type: none"> ▪ <code>ap</code> — All AP related commands. Specify the BSSID of the AP. ▪ <code>client</code> — Clear all wired client related commands. Specify the MAC address of the client. ▪ <code>event</code> — Clears all events. Parameters: <ul style="list-style-type: none"> ▪ <code>database-id</code> — Clear a single event with database id. ▪ <code>event-type</code> — Clear all events with type. ▪ <code>target-mac</code> — Clear all events assigned to a target MAC. ▪ <code>probe</code> — Clear all probe information. Specify the BSSID of the probe.
<code>ap</code>	Clear AP information.
<code>client</code>	Clear client information.
<code>event</code>	Clear event information.
<code>probe</code>	Clear probe information.

Parameter	Description
wired-mac	<p>Clear learned and collected wired-mac information:</p> <ul style="list-style-type: none"> ▪ all — Clear all learned and collected wired mac information. ▪ gw-mac — Clear gateway wired mac information collected from APs. ▪ monitored-ap-wm — Clear monitored AP wired mac information collected from APs. ▪ prop-eth-mac — Clear wired mac information collected from APs. ▪ reg-ap-oui — Clear registered AP OUI information collected from APs. ▪ system-gw-mac — Clear system gateway mac information learned at the controller . ▪ system-wired-mac — Clear system wired mac information learned at the controller. ▪ wireless-device — Clear routers or potential wireless devices information.

Example

The following command clears all aaa counters for all authentication servers:

```
(host) [mynode] #clear aaa authentication-server all
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The <code>clear lc-cluster bucketmap publish counters</code> command was introduced.
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .

Release	Modification
	All instances of <code>master-local-entry</code> have been replaced with <code>conductor-local-entry</code> . All instances of <code>master-local-session</code> have been replaced with <code>conductor-local-session</code> .
ArubaOS 8.8.0.0	The <code>ip dhcp binding ip-address <ip-address></code> parameter was introduced.
ArubaOS 8.6.0.17 and 8.7.1.9	The iap statistics , iap branch-key , and iap subnet-stats parameters were introduced.
ArubaOS 8.6.0.0	The <code>route-cache-v6</code> sub-parameter was added to the <code>datapath</code> parameter.
ArubaOS 8.3.0.0	The <code><port></code> sub-parameter was added to the <code>port</code> parameter.
ArubaOS 8.2.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>master-local</code> ■ <code>mon-serv</code> ■ <code>mon-serv-fwv</code> ■ <code>perf-test</code> ■ <code>web-cc md</code>
ArubaOS 8.0.0.0	Command introduced.

clear amon-receiver

```
show amon-receiver [[dest-stats] | [dest-stats-all] | [dest-stats-inst-0] | [dest-  
stats-inst-1] | [dest-stats-inst-2] | [dest-stats-inst-3] | [dest-stats-inst-4] |  
[dest-stats-inst-5] | [dest-stats-inst-6] | [dest-stats-inst-7] | [dest-table] |  
[error-counters] | [error-counters-all] | [interest-table] | [list-details] |  
[parameter] | [set-debug-level-dest] | [src-stats-all] | [stats-counters] | [stats-  
counters-all]]
```

Description

This command displays AMON receiver information.

Parameter	Description
dest-stats-all	Clear all destination statistics
dest-stats-inst-0	Clears destination statistics instance 0
dest-stats-inst-1	Clears destination statistics instance 1
dest-stats-inst-2	Clears destination statistics instance 2
dest-stats-inst-3	Clears destination statistics instance 3
dest-stats-inst-4	Clears destination statistics instance 4
dest-stats-inst-5	Clears destination statistics instance 5
dest-stats-inst-6	Clears destination statistics instance 6
dest-stats-inst-7	Clears destination statistics instance 7
error-counters	Clears error counters
src-stats-counters	Clears stats counters for a particular source
src-stats-counters-all	Clears all stats counters for all sources
stats-counters	Clears stats counters
stats-counters-all	Clears all stats counters

Example

The following command displays AMON receiver information for destination statistics instance 0:

```
(host) [mynode] #clear amon-receiver dest-stats-inst-0
```

```
Clear Amon Receiver Stats
-----
AMON-RECEIVER
```

clear amon-sender

```
show amon-sender [[dest-stats] | [dest-stats-all] | [dest-stats-inst-0] | [dest-  
stats-inst-1] | [dest-stats-inst-2] | [dest-stats-inst-3] | [dest-stats-inst-4] |  
[dest-stats-inst-5] | [dest-stats-inst-6] | [dest-stats-inst-7] | [dest-table] |  
[error-counters] | [error-counters-all] | [interest-table] | [list-details] |  
[parameter] | [set-debug-level-dest] | [src-stats-all] | [stats-counters] | [stats-  
counters-all]]
```

Description

This command displays AMON sender information. This command must be issued on the managed device.

Parameter	Description
bundle-counters	Clears bundle counters
dest-stats-inst-0	Clears destination statistics instance 0.
dest-stats-inst-1	Clears destination statistics instance 1.
dest-stats-inst-2	Clears destination statistics instance 2.
dest-stats-inst-3	Clears destination statistics instance 3.
dest-stats-inst-4	Clears destination statistics instance 4.
dest-stats-inst-5	Clears destination statistics instance 5.
dest-stats-inst-6	Clears destination statistics instance 6.
dest-stats-inst-7	Clears destination statistics instance 7.
egress-counters	Clears egress counters.
error-counters	Clears error counters.
src-stats-counters	Clears stats counters for a particular source.
src-stats-counters-all	Clears stats counters for all sources.
stats-counters	Clears stats counters.
stats-counters-all	Clears all stats counters.

Example

The following command displays AMON sender information for destination statistics instance 0:

```
(host) [mynode] #logon 192.0.1.12
(MN-7240) #clear amon-sender dest-stats-inst-0
```

Command History

clear wms wired-mac

```
clear wms wired-mac [ all | gw-mac <mac> | monitored-ap-wm <mac> | prop-eth-mac <mac> | reg-ap-oui <mac> | system-gw-mac <mac> | system-wired-mac <mac> | wireless-device <mac>]
```

Description

Clear *learned* and *collected* Wired MAC information. Optionally, enter the MAC address, in **nn:nn:nn:nn:nn:nn** format, of the AP that has seen the Wired MAC.

Parameter	Description
all	Clear all the learned and collected wired Mac information.
gw-mac <mac>	Clear the gateway wired Mac information collected from the APs.
monitored-ap-wm <mac>	Clear monitored AP wired Mac information collected from the APs.
prop-eth-mac <mac>	Clear the wired Mac information collected from the APs.
reg-ap-oui <mac>	Clear the registered AP OUI information collected from the APs.
system-gw-mac <mac>	Clear system gateway Mac information learned at the controller.
system-wired-mac <mac>	Clear system wired Mac information learned at the controller.
wireless-device <mac>]	Clear routers or potential wireless devices information.

clock cli-timestamp

clock cli-timestamp

Description

This command enables the timestamp feature, adding a date and time to the output of `show` commands.

When you enable the timestamp feature, the CLI includes a timestamp in the output of each `show` command indicating when the `show` command was issued. Note that the output of `show clock` and `show log` commands do not include timestamps, even when this feature is enabled. You can disable timestamps using the command `no clock cli-timestamp`.

Example

The following example enables the timestamp feature.

```
(host) [mynode] (config) #clock cli-timestamp
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

clock set

```
clock set <year> <month> <day> <time>
```

Description

This command sets the date and time. You can configure the year, month, day, and time. You must configure all four parameters.

Specify the time using a 24-hour clock. You must specify the seconds.

Parameter	Description
clock set	Sets the time and date.
<year>	Sets the year. Requires all 4 digits. Numeric
<month>	Sets the month. Give the complete month name. january-december
<day>	Sets the day. 1-31
<time>	Sets the time. Specify hours, minutes, and seconds separated by spaces. 0-23 for hours 1-60 for minutes 1-60 for seconds

Example

The following example configures the clock to January 1, 2017, at 16:22:52.

```
(host)[mynode] #clock set 2017 january 1 16 22 52
```

Command History

Release	Modification

clock summer-time recurring

```
clock summer-time <WORD> recurring  
  <1-4> <start day> <start month> <hh:mm>  
  first <start day> <start month> <hh:mm>  
  last <start day> <start month> <hh:mm>  
  <1-4> <end day> <end month> <hh:mm>  
  first <end day> <end month> <hh:mm>  
  last <end day> <end month> <hh:mm>
```

Description

This command sets the software clock to begin and end daylight savings time on a recurring basis. This command subtracts exactly 1 hour from the configured time.

The **WORD** can be any alphanumeric string, but cannot start with a colon (:). A **WORD** longer than five characters is not accepted. If you enter a **WORD** containing punctuations, the command is accepted, but the timezone is set to UTC.

You can configure the time to change on a recurring basis. To do so, set the week, day, month, and time when the change takes effect (daylight savings time starts). You must also set the week, day, month, and time when the time changes back (daylight savings time ends).

The **start day** requires the first three letters of the day. The **start month** requires the first three letters of the month.

You also have the option to set the number of hours by which to offset the clock from UTC. This has the same effect as the [clock timezone](#) command.

Parameter	Description
<WORD>	Abbreviation for your time zone. For example, PDT for Pacific Daylight Time. 3-5 characters
<1-4>	Enter the week number to start and end daylight savings time. For example, enter 2 to start daylight savings time on the second week of the month. 1-4
first	Enter the keyword first to have the time change begin or end on the first week of the month.
last	Enter the keyword last to have the time change begin or end on the last week of the month.
<start day>	Enter the weekday when the time change begins or ends. Sunday-Saturday
<start month>	Enter the month when the time change begins or ends.

Parameter	Description
	January-December
<hh:mm>	Enter the time, in hours and minutes, that the time change begins or ends. 24 hours

Example

The following example sets daylight savings time to occur starting at 2:00 AM on Sunday in the second week of March, and ending at 2:00 AM on Sunday in the first week of November. The example also sets the name of the time zone to PST with an offset of UTC - 8 hours.

```
(host) [mynode] (config) #clock summer-time PST recurring 2 Sun Mar 2:00
first Sun Nov 3:00 -8
```

Related Commands

Command	Description
show clock	Displays the system clock, configured for daylight savings.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

clock timezone

clock timezone <name>

Description

This command sets the timezone on a controller. The `name` parameter can be any alphanumeric string, but cannot start with a colon (:). A time zone name longer than five characters is not accepted. If you enter a time zone name containing punctuation, the command is accepted, but the time zone is set to UTC.

Parameter	Description
<name>	Name of the timezone. 3-5 characters

Example

The following example configures the timezone to PST.

```
(host) [mynode] (config) #clock timezone PST
```

Related Commands

Command	Description
show clock	Displays the system clock under the configured timezone.

clear aaa auth-survivability-cache

clear aaa auth-survivability-cache

Description

This command allows you to clear the data that is currently in the local Survival Server cache.

Parameter	Description
all	Clears all entries in the Authentication Survivability Cache.
station	Clears the entry in the Authentication Survivability Cache for a particular station.
A:B:C:D:E:F	Specify the MAC address of the station.

Example

To clear the auth-survivability cache:

```
(host) [mynode] (config) #clear aaa auth-survivability-cache <all> |  
<station MAC_address>
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

cluster-debug

cluster-debug

```
bucketmap {rebalance | essid <ssid_name> {bucketindex <buck_idx>| active
<active_uac_idx> | standby <standby_uac_idx>}}
standby-aac reassign [[active-aac-ip] <active_aac> [active-aac-ip6]] <active_aac_
v6> [[standby-aac-ip] [standby-aac-ip6]] <new_standby_aac> <new_standby_aac_v6>
[ap-group] <ap-group> [ap-mac] <ap-mac>
calc-sta-uac <sta_mac> <ssid_name>
```

Description

This command set is used to change the bucketmap entries and to reassign the standby AAC. However, changing the bucketmap entries is not recommended by Aruba.

Parameter	Description
bucketmap	Bucket map.
rebalance	Evenly rebalance bucketmap distribution based on the cluster node's platform capacity. NOTE: The cluster-debug bucketmap rebalance command is disruptive and disconnects all the connected clients. To minimize impact on clients, run this command with caution, possibly during a maintenance window.
ssid <ssid_name>	Essid name.
Bucketindex <0-255>	Index within bucket map. The valid range of values for index is <0-255>.
active <0-11>	Index of UAC in bucket map's UAC List. The valid range of values for index is <0-11>.
standby <standby_uac_idx>	Standby UAC . Index of UAC in bucket map's UAC List or -1 if no standby desired. The valid range of values for index is <0-11>.
calc-sta-uac	Calculate station UAC and index by using bucketmap in GSM channel.
<sta_mac>	Enter the station MAC Address.
<ssid_name>	Enter the Essid name.
standby-aac	Standby AAC.
reassign	Reassign Standby AAC.

Parameter	Description
active-aac-ip <active_aac>	Active AAC IP Address. Enter the IP address of Active AAC. Use the following parameters: <ul style="list-style-type: none"> standby-aac-ip <new_standby_aac>: Enter the IP Address of new standby AAC. standby-aac-ip6 <new_standby_aac_v6>: Enter the IPv6 Address of new standby AAC.
active-aac-ip6 <active_aac_v6>	Active AAC IPv6 Address. Enter the IPv6 address of Active AAC.
ap-group <ap-group>	Enter the AP Group name. Use the following parameters: <ul style="list-style-type: none"> active-aac-ip <active_aac>: Enter the IP Address of active AAC. active-aac-ip6 <active_aac_v6>: Enter the IPv6 Address of active AAC. standby-aac-ip <new_standby_aac>: Enter the IP Address of new standby AAC. standby-aac-ip6 <new_standby_aac_v6>: Enter the IPv6 Address of new standby AAC.
ap-mac <ap_mac>	Enter the AP MAC Address.

Command History

Release	Modification
ArubaOS 8.6.0.17 and 8.7.1.9	The bucketmap rebalance parameter was introduced.
ArubaOS 8.2.0.0	The <code>calc-sta-uac</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

cluster-member-custom-cert

```
cluster-member-custom-cert member-mac <mac> ca-cert <ca> server-cert <cert>  
suite-b <gcm-128 | gcm-256>]
```

Description

This command sets the managed device as a CPsec cluster root, and specifies a custom user-installed certificate for authenticating cluster members. If your network includes multiple Mobility Conductor each with their own hierarchy of APs and managed device, you can allow APs from one hierarchy to failover to any other hierarchy by defining a cluster of Mobility Conductor. Each cluster will have one Mobility Conductor as its cluster root, and all other managed devices as cluster members.

To define a managed device as a cluster root, issue one of the following commands on that managed device:

- [cluster-member-custom-cert](#): Define the Mobility Conductor as a cluster root, and select a user-installed certificate to authenticate that cluster member.
- [cluster-member-factory-cert](#): Define the Mobility Conductor as a cluster root, and select a factory-installed certificate to authenticate that cluster member.
- [cluster-member-ip](#) : Define the Mobility Conductor as a cluster root, and set the IPsec key to authenticate that cluster member.

For information on installing certificates on your controller, refer to the *Management Utilities* chapter of the *ArubaOS User Guide*.

Parameter	Description
member-mac <ca>	MAC address of the cluster member.
ca-cert <ca>	Name of the CA certificate uploaded via the WebUI.
ca-cert <ca>	Name of the CA certificate uploaded via the WebUI.
server-cert <cert>	Name of the server certificate uploaded via the WebUI.
suite-b	To use Suite-B encryption in the secure communication between the cluster root and cluster member, specify one of the following Suite-B algorithms: <ul style="list-style-type: none">▪ gcm-128: Encryption using 128-bit AES-GCM▪ gcm-256: Encryption using 256-bit AES-GCM

Example

The following example selects a customer installed certificate for cluster member authentication.

```
(host) (config) # cluster-member-custom-cert member-mac 00:1E:37:CB:D4:52 ca-  
cert cacert1 server-cert servercert1
```

Related Commands

cluster-member-factory-cert

cluster-member-factory-cert member-mac <mac>

Description

This command sets the managed device as a CPsec cluster root, and specifies a custom user-installed certificate for authenticating cluster members. To define a controller as a cluster root, issue one of the following commands on that controller:

- [cluster-member-custom-cert](#): Define the managed device as a cluster root, and select a user-installed certificate to authenticate that cluster member.
- [cluster-member-factory-cert](#): Define the managed device as a cluster root, and select a factory-installed certificate to authenticate that cluster member.
- [cluster-member-ip](#): Define the Managed device as a cluster root, and set the IPsec key to authenticate that cluster member.

For information on installing certificates on your controller, refer to the *Management Utilities* chapter of the *ArubaOS User Guide*.

Parameter	Description
<mac>	MAC address of the user-installed certificate on the cluster member.

Example

The following command sets the managed device on which you issue command as a root managed device, and adds the managed device **172.21.18.18** as a cluster member with the IPsec key **ipseckey1**:

```
(host) (config) #cluster-member-factory-cert member-mac 00:1E:37:CB:D4:52
```

Related Commands

Parameter	Description
control-plane-security	Configure the CPsec profile.

Parameter	Description
<u>show cluster-config</u>	Show the multi-master/conductor cluster configuration for the CPsec feature.
<u>show cluster-switches</u>	Issue this command on a Mobility Conductor using CPsec in a multi-master environment to show other managed devices to which it is connected.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on managed devices.

cluster-member-ip

```
cluster-member-ip <ip-address>  
    ipsec <key>
```

Description

This command sets the Mobility Conductor as a CPsec cluster root, and specifies the IPsec key for a cluster member. The Mobility Conductor operating as the cluster root will use the CPsec feature to create a self-signed certificate, then certify its own managed devices and APs. Next, the cluster root will send the certificate to each cluster member, which in turn certifies their own managed devices and APs. Since all managed devices and APs in the cluster get their certificates from the cluster root, they will all have the same trust anchor, and the APs can switch to any other managed device in the cluster and still remain connected to the secure network.

Issue the [cluster-member-ip](#) command on the Mobility Conductor you want to define as the cluster root to set the IPsec key for secure communication between the cluster root and each cluster member. Use the IP address **0.0.0.0** in this command to set a single IPsec key for all member managed devices, or repeat this command as desired to define a different IPsec key for each cluster member.

Once the cluster root has defined an IPsec key for all cluster members, you must access each of the member managed devices and issue the command [cluster-root-ip](#) to define the IPsec key for communication to the cluster root.

Parameter	Description
<ip-address>	Switch IP address of a CPsec cluster member. You can also use the IP address 0.0.0.0 to set a single IPsec key for all cluster members.
ipsec <key>	Configure the value of the IPsec key for secure communication between the cluster root and the specified cluster member. The key must be between 6-64 characters.

Example

The following command sets the managed device on which you issue command as a root managed device, and adds the managed device **172.21.18.18** as a cluster member with the IPsec key **ipseckey1**:

```
(host) (config) #cluster-member-ip 172.21.18.18 ipsec ipseckey1
```

Related Commands

Parameter	Description
control-plane-security	Configure the CPsec profile.
show cluster-config	Show the multi-master/conductor cluster configuration for the CPsec feature.
show cluster-switches	Issue this command on a Mobility Conductor using CPsec in a multi-master environment to show other managed devices to which it is connected.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

cluster-root-ip

```
cluster-root-ip <ip-address>  
  ipsec <key>  
  ipsec-custom-cert root-mac1 <mac1> [root-mac2 <mac2>] ca-cert <ca> server-cert  
  <cert> [suite-b <gcm-128 | gcm-256>]  
  ipsec-factory-cert root-mac-1 <mac> [root-mac-1 <mac>]
```

Description

This command sets the Mobility Conductor as a CPsec cluster member, and defines the IPsec key or certificate for secure communication between the cluster member and the Mobility Conductor's cluster root.

Parameter	Description
<ip-address>	The IP address of CPsec cluster root Mobility Conductor. To set a single IPsec key for all member managed devices in the cluster, use the IP address 0.0.0.0 .
ipsec <key>	Set the value of the IPsec PSK for communication with the cluster root. This parameter must be have the same value as the IPsec key defined for the cluster member via the cluster-member-ip command.
ipsec-factory-cert	Use a factory-installed certificate for secure communication between the cluster root and the specified cluster member by specifying the MAC address of the certificate.
root-mac-1 <mac>	Specify MAC address of the cluster root.
ipsec-custom-cert	Use a custom user-installed certificate for secure communication between the cluster root and the specified cluster member.
root-mac-1 <mac>	Specify the MAC address of the cluster-root's certificate.
root-mac-2 <mac>	(Optional) If your network has multiple Mobility Conductor, use this parameter to specify he MAC address of the redundant cluster-root's certificate.
ca-cert <ca>	Name of the CA certificate uploaded via the WebUI
server-cert <cert>	Name of the server certificate uploaded via the WebUI.
suite-b	To use Suite-B encryption in the secure communication between the cluster root and cluster member, specify one of the following Suite-B algorithms <ul style="list-style-type: none">▪ gcm-128: Encryption using 128-bit AES-GCM▪ gcm-256: Encryption using 256-but AES-GCM

Example

The following command defines the IPsec key for communication between the cluster member and the root managed device **172.21.45.22**:

```
(host) [mynode] (config) #cluster-root-ip 172.21.45.22 ipsec ipseckey1
```

Related Commands

Parameter	Description
control-plane-security	Configure the CPsec profile.
show cluster-config	Show the multi-master/conductor cluster configuration for the CPsec feature.
show cluster-switches	Issue this command on a Mobility Conductor using CPsec in a multi-master environment to show other managed devices to which it is connected.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on managed devices.

cm_mu_client_thresh

cm-mu-client-thresh <count>

Description

This ClientMatch command configures the client threshold on a multi-user-capable (MU-capable) radio. This command is used when MU-capable clients attempt to steer to a MU-capable radio. Clients are not steered to radios that have already met the client threshold, preventing the need for load-balancing.

Parameter	Description
count	Total number of clients that can be associated to a radio, in which the radio can still be considered for MU-steering. 15

Example

The following example configures a threshold of 12 clients on a MU-MIMO-capable radio:

```
(host) (config) #cm-mu-client-thresh <12>
```

Command History

Version	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters.	Config mode on Mobility Conductor.

cm_mu_snr_thresh

cm-mu-snr-thresh <value>

Description

This ClientMatch command configures the Signal to Noise Ratio (SNR) threshold for a multi-user-capable (MU-capable) radio. The **cm-mu-snr-thresh** value must be greater than the **cm-sticky-snr** value for a MU-capable client to be steered to that radio.

Parameter	Description
value <dB>	Minimum SNR value of a client on the target radio, in which the radio can still be considered for MU-steering. > 25 30

Example

The following example configures an SNR threshold of 90 on a MU-MIMO-capable radio:

```
(host) (config) #cm-mu-snr-thresh <90>
```

Command History

Version	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters.	Config mode on Mobility Conductor.

command-set-profile

command-set-profile <profile-name>

Description

This command configures a command set profile.

Parameter	Description
<profile-name>	Specify name of the profile to configure.

Example

```
(host) [mynode] (config) #command-set-profile default
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command requires the PEFNG license.	Configure mode on Mobility Conductor.

controller-amon

```
controller-amon  
  bssid-tunnel-stats
```

Description

This command configures controller AMON process.

Parameter	Description
bssid-tunnel-stats	Enable sending cluster statistics in AMON feed.

Example

```
(host) [mynode] (config) #controller-amon bssid-tunnel-stats
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command requires the PEFNG license.	Configure mode on Mobility Conductor.

controller-ble

```
controller-ble  
  opmode { disabled| PersistentConsole}
```

Description

This command displays controller information.

Parameter	Description
opmode	Configure one of the following BLE operational mode for 90xx series controllers: <ul style="list-style-type: none">■ disabled: BLE is turned off.■ PersistentConsole: BLE radio allows serial console access over BLE alongwith beaconing.

Example

```
(host) [mynode] (config) #controller-ble opmode PersistentConsole
```

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command requires the PEFNG license.	Configure mode on Mobility Conductor.

controller-ble opmode

```
disabled  
persistentconsole
```

Description

This command configures the BLE operation mode of a controller.

Parameter	Description
disabled	In the disabled opmode, the BLE radio in a controller is turned off. Disabled
persistentconsole	In the persistentconsole opmode, the BLE radio in a controller allows serial console access over BLE along with beaconing.

Command History

Release	Modification
ArubaOS 8.7.0.0	The <code>beaconing</code> parameter was removed.
ArubaOS 8.5.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

control-plane-security

```
control-plane-security
  auto-cert-allow-all
  auto-cert-allowed-addr <start> <end>
  auto-cert-allowed-addr <startv6> <endv6>
  auto-cert-prov
  cpsec-enable
  no
  timer
```

Description

Configure the control plane security profile by identifying APs to receive security certificates.

The managed devices enabled with control plane security only send certificates to APs that you have identified as valid APs on the network. If you are confident that all campus APs currently on your network are valid APs, you can configure automatic certificate provisioning to send certificates from the managed device to each campus AP, or to all campus APs within a specific range of IP addresses. If you want closer control over each AP that gets certified, you can manually add individual campus APs to the secure network by adding each AP's information to a campus AP whitelist/allowlist.

Parameter	Description
<code>auto-cert-allow-all</code>	When you issue the control-plane-security auto-cert-allow-all command, the managed device sends a certificate to all associated APs when auto certificate provisioning is enabled. When disabled, the managed device sends certificates only to APs whose IP or IPv6 addresses are in the ranges specified by auto-cert-allowed-addr .
<code>auto-cert-allowed-addr <start> <end></code>	Use this command to define a specific range of AP IP addresses. The managed device sends certificates to the APs in this IP range when auto certificate provisioning is enabled. Identify a range by entering the starting IP address and the ending IP address in the range, separated by a single space. You can repeat this command as many times as necessary to define multiple IP ranges.
<code>auto-cert-allowed-addr <startv6> <endv6></code>	Use this command to define a specific range of AP IPv6 addresses. The managed device sends certificates to the APs in this IPv6 range when auto certificate provisioning is enabled. Identify a range by entering the starting IPv6 address and the ending IPv6 address in the range, separated by a single space. You can repeat this command as many times as necessary to define multiple IP ranges.

Parameter	Description
<code>auto-cert-prov</code>	Issue this command to enable automatic certificate provisioning. When this feature is enabled, the managed device will attempt to send certificates to associated APs. To disable this feature, use the command <code>no auto-cert-prov</code> . Automatic certificate provisioning is disabled by default
<code>cpsec-enable</code>	Issue this command to enable control plane security. To disable this feature, use the command <code>no cpsec-enable</code> . Control plane security is enabled by default.
<code>no</code>	Negates any configured parameter.
<code>timer <timer></code>	Timer value, in dd:hh (days:hours) format, that prevents APs from going into unapproved-no-cert state when the APs remain idle for two or more hours. The minimum value of hours in dd:hh format is 2 hours.

Example

The following command defines a range of IP addresses that should receive certificates from the managed device, and enables the control plane security feature:

```
(host) [md] (config) #control-plane-security
auto-cert-allowed-addr 10.21.18.10 10.21.10.90
cpsec-enable
```

Related Commands

Command	Description
show control-plane-security	Displays the configured control plane security profile settings.

Command History

Release	Modification
ArubaOS 8.3.0.0	The <code>timer</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

configuration device

```
configuration device
  default-node <node-path>
  file <mac address>
  <mac-address> device-model
  {A7005|A7008|A7010|A7024|A7030|A7205|A7210|A7220|A7240|A7240XM|A7280|MC-VA}
  [<config-path>] |move-to[<dest-path>] [<mac-address-2>]
```

Description

This command maps a device to an existing node in the configuration hierarchy.

The node to which the device is mapped is specified by the `node-path`, which can be an absolute path from the root node or relative path from the current node. If the `node-path` is not specified, the device is mapped to the current node. A device-specific node is created to store the configuration for the device. The node is named using the specified MAC address of the device.

Use the `show configuration devices` command to view the complete list of devices provisioned on your Mobility Conductor, and the `show configuration node-hierarchy` command to view the list of all nodes in the configuration hierarchy.

Parameter	Description
<code>default-node <node-path></code>	Specifies the node to which any device without explicit device-node mapping is attached. If a default node is not configured, unknown devices cannot connect to Mobility Conductor.
<code>file</code>	Use file for initially configuring the node
<code><mac-address></code>	MAC address of the device to be added.
<code><mac-address></code>	MAC address of a device that must be mapped to a node in the configuration hierarchy.
<code>device-model</code>	Model number for the device: <ul style="list-style-type: none">▪ A7005▪ A7008▪ A7010▪ A7024▪ A7030▪ A7205▪ A7210▪ A7220▪ A7240▪ A7240XM▪ A7280▪ MC-VA

Parameter	Description
<config-path>	Full configuration path to which the device is mapped. If the path is not specified, the device is mapped to the current node.
move-to <dest-path>	Moves the device to the specified configuration path of the destination node.
<mac-address-2>	MAC address of the destination node in the configuration hierarchy.

Example

The following command specifies **/md** as the default node:

```
(host) [mynode] (config) #configuration device default-node /md
```

Command History

Release	Modification
ArubaOS 8.3.0.0	The <code>A7280</code> option was added under the <code>device-model</code> parameter.
ArubaOS 8.2.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>move-to</code> ■ <code>dest-path</code> ■ <code>mac-address-2</code>
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

configuration node

```
configuration node
  replace-config <filename> [ignore-masterip-config] [<node-path>]
  replace-config-reboot
  <node-path>
    clone-from <source-path>
    file config-file <filename>
    move-to <dest-path>
```

Description

This command configures nodes in the configuration hierarchy. Node name and location are specified by the node-path, which can be an absolute path from the root node or relative path from the current node. Use this command to view the list of all nodes in the configuration hierarchy.

Parameter	Description
replace-config <filename>	New configuration file to be applied for the specified node.
ignore-masterip-config	(Optional) Ignores any master/conductor IP related changes from the specified configuration file.
<node-path>	(Optional) Path of the configuration node to which the new configuration is to be applied.
replace-config-reboot <filename1>	Replace node's configuration with the configuration file name provided and then reboot.
<node-path>	Path of the configuration node to be added, removed, or moved.
clone-from <source-path>	Copies an existing node's configuration to a new node. The source and destination node names and locations are specified by the source node-path and node-path, respectively.
file config-file <filename>	Use configuration file for initially configuring the node.
move-to <dest-path>	Moves an existing user-created node in the hierarchy to the specified destination node. System-generated nodes cannot be moved. Ensure the following points while moving a node or device, otherwise the move operation will fail: <ul style="list-style-type: none">▪ The node to be moved is a leaf node and does not have any group node or a device node as a child node under it.▪ No configuration is pending on the parent nodes of the child node to be moved.▪ The configuration on the node to be moved is compliant with the configuration in the new ancestor nodes chain.

Example

The following command clones the **/md/group2** node-path to the **/md/group1** node:

```
(host) [mynode] (config) #configuration node /md/group1 clone-from /md/group2
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>move-to</code> sub-parameter was introduced under the <code><node-path></code> parameter.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

configuration purge-pending-config

configuration purge-pending-config [<node-path>]

Description

This command cleans up any pending configurations on nodes in the configuration hierarchy. Issue this command without the <node-path> parameter to purge all pending configurations in the hierarchy. Use the `show configuration node-hierarchy` command to view the list of all nodes in the configuration hierarchy.

Parameter	Description
<node-path>	Path of the configuration node to be purged.

Example

The following command cleans up pending configuration on the **/md** node:

```
(host) [mynode] (config) #configuration purge-pending-config /md
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

configuration rename

```
configuration rename  
  <old-path>  
  <new-path>
```

Description

This command renames a node path to the specified new name.

Parameter	Description
<old-path>	Name and path of the node to be renamed.
<new-path>	Renames the existing node name to the specified name. The node paths of the child nodes under the renamed node are automatically updated.

Example

The following command renames the **/md/node1** node-path to the **/md/node2** node:

```
(host) [mynode] (config) #configuration rename /md/node1 /md/node2
```

Command History

Release	Modification
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

configure terminal

```
configure terminal
  ids unauthorized-device-profile <profile name>
    detect-wifi-direct-p2p-groups | wifi-direct-network-quiet-time | protect-wifi-
    direct-p2p-groups
```

Description

This command allows you to enter the configuration mode. Starting from ArubaOS 8.11.0.0, this command allows you to configure the Wi-Fi Direct settings of an **IDS Unauthorized Device** profile.

Parameter	Description
<code>ids unauthorized-device-profile <profile name></code>	Name of the IDS Unauthorized Device profile.
<code>detect-wifi-direct-p2p-groups</code>	Indicates if the Wi-Fi Direct detection is turned on or off.
<code>wifi-direct-network-quiet-time</code>	The wait time, in seconds, after detecting a Wi-Fi Direct network, after which the check can be resumed. NOTE: The minimum wait time is 60 seconds.
<code>protect-wifi-direct-p2p-groups</code>	Indicates the containment of peers associated with WIFI-Direct GO and devices in a WIFI Direct group, which are connected to a WLAN Infrastructure.

Examples

The following example shows how to execute the `configure terminal` command:

```
(host) # configure terminal
(host) (config) #
```

To return to enable mode, enter `Ctrl-Z` or `exit`.

The following example enables the **Detect WIFI-Direct P2P Groups** parameter:

```
(host) # configure terminal ids unauthorized-device-profile test
```

```
(host) (IDS Unauthorized Device Profile "test")# detect-wifi-direct-p2p-groups
```

The following example configures the wait time for detecting a Wi-Fi Direct network to 120 seconds:

```
(host) # configure terminal ids unauthorized-device-profile test
(host) (IDS Unauthorized Device Profile "test")# wifi-direct-network-quiet-time 120
```

The following example enables the **Protect From WIFI-Direct P2P Groups** parameter:

```
(host) # configure terminal ids unauthorized-device-profile test
(host) (IDS Unauthorized Device Profile "test")# protect-wifi-direct-p2p-groups
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The <code>ids unauthorized-device-profile</code> parameter is introduced.
ArubaOS 8.0.0.0	Command introduced

Command Information

Platforms	License	Command Mode

controller ble-init-action

```
controller ble-init-action apb-power-reset | clear-all-beacons | clear-all-log-  
mac-filters | clear-log-mac-filter | log-level | log-level-str |log-mac-filter |  
msg-select |  
ota-fw-upgrade | remove-beacon-mac | send-apb-update | send-update | start-log  
| stop-log | zigbee permit-joining restart <all> | <mac>
```

Description

This command will initiate BLE action for controller.

Parameter	Description
apb-power-reset	This parameter will power-on reset for the on-board BLE radio.
clear-all-beacons	This parameter will delete all beacon data.
clear-all-log-mac-filters	This parameter will clear all the BLE daemon log MAC filters.
clear-log-mac-filter	This parameter will clear the BLE daemon log MAC filter.
log-level	BLE daemon log level specified as a number.
log-level-str	BLE daemon log levels specified as comma-separated values (without quotes). Possible values: 'info','warning','error','ageout','bmreq','fw-upgrade',' fw-upgradeerr','cfgupdate','cfgupdateerr','beacon','bcntl v','bcnerr','apb','tags','zf','amon','iot_gw','at-https- json','at-websocket-protobuf'.
log-mac-filter	BLE daemon log MAC filter.
msg-select	Sets bits to enable specific messages from APB to controller BLE Daemon - refer to BLE config CLI command.
ota-fw-upgrade	Over the Air firmware upgrade for onboard BLE.
remove-beacon-mac	Deletes beacon with matching MAC address.
send-apb-update	Sends APB info update to BLE Relay on controller.
send-update	Sends IoT payload message to BMC immediately.
start-log	Enables BLE Daemon logging.
stop-log	Disables BLE Daemon logging.
zigbee permit-joining restart	Re-starts zigbee initial permit joining duration.

Parameter	Description
all	Re-starts all devices.
mac <mac-address>	Re-starts specific devices.

Example

```
(host) [mynode] #controller ble-init-action stop-log
```

Command History

Release	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

controller-ip

```
controller-ip {loopback|vlan <id>}
```

Description

This command sets the IP address of the managed device to the loopback interface address or a specific VLAN interface address.

This command allows you to set the managed device IP to the loopback interface address or a specific VLAN interface address. If the managed device IP command is not configured, the managed device IP defaults to the loopback interface address. If the loopback interface address is not configured, the first configured VLAN interface address is selected. Generally, VLAN 1 is the factory default setting and thus becomes the managed device IP address.

Parameter	Description
loopback	Sets the IP address to the loopback interface. Disabled
vlan <id>	Sets the IP address to a VLAN interface.

Example

The following command sets the IP address to VLAN interface 6.

```
(host) [md] #controller-ip vlan 6
```

Related Commands

Command	Description
show controller-ip	Displays the controller's IP address and VLAN interface ID.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
Available on all platforms	Base operating system.	Config mode on Mobility Conductor.

controller-ipv6

```
controller-ipv6 [loopback|{vlan <VLAN ID>}]  
no ...
```

Description

This command sets the default IPv6 address of the Mobility Conductor to the IPv6 loopback interface address or a specific VLAN interface address.

This command allows you to set the default IPv6 address of the Mobility Conductor to the IPv6 loopback interface address or a specific IPv6 VLAN interface address. If the Mobility Conductor IPv6 command is not configured then the Mobility Conductor IP defaults to the loopback interface address. If the loopback interface address is not configured then the first configured VLAN interface address is selected. Generally, VLAN 1 is the factory default setting and thus becomes the Mobility Conductor IP address.

Parameter	Description
loopback	Sets the managed device IP to the loopback interface. Disabled
vlan	Set the managed device IP to a VLAN interface.
vlan <id>	Specifies the VLAN interface ID.
address <X:X:X:X::X>	Specifies the IPv6 address.

Example

The following command sets the Mobility Conductor IP address to VLAN interface 6:

```
(host) [mynode] (config) #controller-ipv6 vlan 6
```

The following example displays the use of extended scope of address range:

```
(host) [mynode] (config) #controller-ipv6 vlan 294 address 2942::5
```

Related Commands

usb: partition <part> <usbfilename> {flash: <flashfilename>|system: partition
{0|1}}
```

copy-provisioning-params

Description

This command copies files to and from the managed device.

Use this command to save back-up copies of the configuration file to an FTP or TFTP server, or to load a saved file from an FTP or TFTP server.

Three partitions reside on the file system flash. Totalling 256MB, the three partitions provide space to hold the system image files (in partitions 1 and 2 which are 45MB each) and user files (in partition 3, which is 165MB). System software runs on the system partitions; the database, DHCP, startup configuration, and logs are positioned on the user partition.

To restore a database, copy the database from the network server and import the database.

To restore a configuration file, copy the file from network server to the managed device's flash system then copy the file from the flash system to the system configuration. This ensures that you do not accidentally overwrite your system startup configuration file.

Unlike the managed device's flash, the USB device has more than two partitions; not just 0 and 1. When copying a file from a USB device, you must know which partition the target file is on. Use the `show storage` command to identify the location of the file to identify the correct USB partition.

Parameter	Description
flash: <srcfilename>	Copies the contents of the managed device's flash file system, the system image, to a specified destination.
flash:	Copies the file to the flash file system.
<destfilename>	New name of the copied file.

Parameter	Description
ftp:	Copies the file to the FTP file system.
<ftphost>	IPv4 or IPv6 address of the FTP server.
<user>	Name of the FTP user.
<remote-dir>	Name of the remote directory.
<destfilename>	New name of the copied file.
scp:	Copies the file to the SCP file system.
<scphost>	IPv4 or IPv6 address of the remote SCP host.
<username>	Username for secure login.
<destfilename>	New name of the copied file.
tftp:	Copies the file to a TFTP server.
<tftphost>	IP address of the TFTP server.
<destfilename>	New name of the copied file.
usb:	Copies the file to an attached USB storage device.
partition	Specifies the partition on the USB device (0,1).
<destfilename>	New name of the copied file.
ftp:	Copies a file from the FTP server.
<ftphost>	IPv4 or IPv6 address or hostname of the FTP server.
<user>	User account name required to access the FTP server.
<filename>	Full name of the file to be copied.
partition	Specifies the system partition to save the file (0,1).
running-config	Copies the active or running configuration to a specified destination.
flash:	Copies the configuration to the flash file system.
<filename>	New name of the copied configuration file.
ftp:	Copies the configuration to an FTP server.
<ftphost>	IP address of the FTP server.

Parameter	Description
<user>	User account name required to access the FTP server.
<filename>	New name of the copied configuration file.
<remote-dir>	Specifies a remote directory, if needed.
startup-config	Copies the active, running configuration to the start-up configuration.
tftp:	Using TFTP, copy the configuration to a TFTP server.
<tftphost>	Specifies the IP address or hostname of the TFTP server.
<filename>	New name of the copied configuration file.
scp:	Copies an ArubaOS image file or file from the flash file system using the Secure Copy protocol. The SCP server or remote host must support SSH version 2 protocol.
<scphost>	IPv4 or IPv6 address of the SCP server or remote host.
<username>	User account name required to access the SCP server or remote host.
<filename>	Absolute path of the filename to be copied.
flash:	Copies the file to the flash file system.
<destfilename>	New name of the copied file.
system:	Copies the file to the system partition.
partition	Specifies the system partition to save the file (0,1).
system:	Copies the specified system partition.
<srcpartition>	Disk partition from which to copy the system data (0,1).
<destpartition>	Disk partition to copy the system data to (0,1).
tftp:	Copies a file from the specified TFTP server to either the controller or another destination. This command is typically used when performing a system restoration, or to pull a specified file name into the wms database.
<tftphost>	IPv4 or IPv6 address of the TFTP server.
<filename>	Full name of the file to be copied.
flash:	Copies the file to the flash file system.

Parameter	Description
<destfilename>	New name of the copied file.
system:	Copies the file to the system partition.
partition	Specifies the system partition to save the file (0,1).
usb:	Copies a file from an attached USB device to the flash file system.
partition <part>	Specifies the partition on the USB device (0,1).
<usbfilename>	Full name of the USB file to be copied.
flash:	Copies the file to the flash file system.
<flashfilename>	New name of the copied file.
system:	Copies the file to the system partition.
partition	Specifies the system partition to save the file (0,1).

Example

The following commands copy the configuration file named "engineering" from the TFTP server to the managed device's flash file system, and then uses that file as the startup configuration. This example assumes the startup configuration file is named default.cfg:

```
(host) [mynode] (config) #copy tftp: 192.0.2.0 engineering flash:
default.bak
copy flash: default.bak flash: default.cfg
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

copy-provisioning-params

```
copy-provisioning-params  
  ap-name <ap-name>  
  ip-addr <ip-addr>
```

Description

This command copies a provisioning-ap-list entry to provisioning-params.

Parameter	Description
ap-name <ap-name>	Specify the AP name for which data provisioning is to be used.
ip-addr <ip-addr>	Specify the IP address for which data provisioning is to be used.

Example

```
(host) [mynode] #copy-provisioning-params ap-name default
```

cp-bandwidth-contract

```
cp-bandwidth-contract <string> pps <1...256000>
```

Description

This command configures a bandwidth contract traffic rate, which can then be associated with a whitelist/allowlist session ACL.

Parameter	Description
<string>	Name of the bandwidth contract.
<1...256000>	Bandwidth rate in packets per second (pps). NOTE: It is recommended that you do not exceed 96000 packets per second or you may encounter buffer allocation issues. 1-256000

Example

The following example configures a bandwidth contract named “cp-rate” with a rate of 100 pps.

```
(host) [mynode] (config) #cp-bandwidth-contract cp-rate pps 100
```

Related Commands

Command	Description
show cp-bwcontracts	Displays a list of control processor bandwidth contracts for whitelist/allowlist ACLs.
firewall cp	This command creates a new whitelist/allowlist ACL and can associate a bandwidth contract with that ACL.

Command History

Version	Modification
ArubaOS 8.0.0.0	Command introduced.

```

Descriptions

This command configures Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP).

Parameter	Description
allow-via-subnet-routes	Configures VIA clients to push subnet routes to Mobility Conductor.
ca-certificate	Assigns the Certificate Authority (CA) certificate used to authenticate VPN clients.
certificate-group	Configures an IKE certificate group for VPN Clients.
disable-aggressive-mode	Disables the IKEv1 aggressive mode.
disable-ipcomp	Disables IP compression on Mobility Conductor.

Parameter	Description
dpd	Configures IKE DPD.
key	Configures the IKE preshared key for site-to-site VPN.
key-hex	Configures the IKE PRE-SHARED key for hex-based characters [0-9,a-f,A-F].
max-allowed-negotiations	Configures the maximum allowed in negotiations value. Exchanges will be throttled after this max limits
max-allowed-ikev1-exchanges	Configures the maximum allowed in-negotiation ikev1 exchanges. Exchanges will be throttled after this max limits.
permit-invalid-cert	Allows invalid or expired certificates to be used for site-to-site VPN.
ppk-add	Configure Postquantum Preshared Key (PPK).
ppk-delete	Delete Postquantum Preshared Key (PPK).
ppk	Configures the IKE Postquantum Preshared Key (PPK).
route ipsec	Configures the subnet route using an IPsec map.
sa-cleanup	Enables the cleanup of IKE SAs.
server-certificate	Assigns the server certificate used to authenticate the Mobility Conductor or managed device for VPN clients using IKEV1 or IKEV2.
use-TPMcert	Use TPM certificate.
xauth	Enables IKE XAuth for VPN clients.

Command History

Release	Modification
ArubaOS 8.10.0.0	The <code>ppk</code> parameter was introduced.
ArubaOS 8.8.0.0	The <code>maximum-allowed-negotiations</code> parameter was introduced.
ArubaOS 8.0.1.0	The <code>allow-via-subnet-routes</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

crypto-local isakmp allow-via-subnet-routes

crypto-local isakmp allow-via-subnet-routes

Description

This command allows VIA clients to push subnet routes to Mobility Conductor.

Example

This command enables VIA clients to push subnets to Mobility Conductor:

```
(host) [mynode] (config) #crypto-local isakmp allow-via-subnet-routes
```

Related Commands

Command	Description
show crypto-local isakmp	Indicates if Mobility Conductor can accept subnet routes from VIA clients.

```

Description

This command configures IPsec mapping for site-to-site VPNs.

You can use Mobility Conductor instead of VPN concentrators to connect sites at different physical locations.

You can configure separate CA and server certificates for each site-to-site VPN. You can also configure the same CA and server certificates for site-to-site VPN and client VPN. Use the `show crypto-local ipsec-map` command to display the certificates associated with all configured site-to-site VPN maps; use the **tag <map>** option to display certificates associated with a specific site-to-site VPN map.

Mobility Conductor supports site-to-site VPNs with two statically addressed managed device, or with one static and one dynamically addressed managed device. By default, site-to-site VPN uses

IKE Main-mode with Pre-Shared-Keys to authenticate the IKE SA. This method uses the IP address of the peer, and therefore will not work for dynamically addressed peers.

To support site-site VPN with dynamically addressed devices, you must enable IKE Aggressive-Mode with Authentication based on a Pre-Shared-Key. A managed device with a dynamic IP address must be configured to be the initiator of IKE Aggressive-mode for Site-Site VPN, while the managed device with a static IP address must be configured as the responder of IKE Aggressive-mode.

IKEv2 site-to-site VPNs between Mobility Conductor and 7000 Series Mobility Conductor support traffic compression between those devices. When this hardware-based compression feature is enabled, the quality of unencrypted traffic (such as Skype4b or Voice traffic) is not compromised by increased latency or decreased throughput.

Parameter	Description
<code><map></code>	Name of the IPsec map.
<code><priority></code>	Priority of the entry. 1-9998
<code>client-mode [<nat> <network>]</code>	Enables client-mode where: nat enables nat mode with any and any. network enables network mode
<code>dst-net</code>	IP address and netmask for the destination network.
<code>disable</code>	Disables an existing IPsec map. New maps are enabled by default.
<code>dst-net <ipsec-map-dst-net> <ipsec-map-dst-mask> any</code>	IP address and netmask for the destination network.
<code>dst-net-ipv6 <ipsec-map-dst-net-ipv6> <ipsec-map-dst-prefix-len></code>	IPv6 address and netmask for the destination network.
<code>enrolled-cert-auth</code>	Enables the enrolled certificate authentication for site-to-site tunnel.
<code>factory-cert-auth</code>	Enables factory certificate authentication for site-to-site VPNs. Disabled
<code>force-natt</code>	Include this parameter to always enforce UDP 4500 for IKE and IPsec. This option is disabled by default. Disabled
<code>force-tunnel-mode</code>	Configures the force-tunnel-mode flag.

Parameter	Description
<code>ip access-group</code>	Configures the IP access group name.
<code>ip <access-group></code>	Attaches a route ACL to the IPsec map for a site-to-site VPN. When you associate a routing ACL to inbound traffic on a Mobility Conductor terminating a site-to-site VPN, that ACL can forward traffic as normal, route traffic to a nexthop router on a nexthop list, or redirect traffic over an L3 GRE tunnel or tunnel group. For more information on creating a routing ACL, see ip access-list route .
<code>session-acl <session acl name></code>	Configures session ACL on IPsec map.
<code>ip-compression</code>	Enable compression for traffic in an IKEv2 site-to-site tunnel between a master/conductor and local 7000 Series Mobility Conductor. Compression is disabled by default. Disabled
<code>ipsec-mtu <mtu></code>	Configures the IPsec MTU of the security association (SA). NOTE: Starting from ArubaOS 8.11.0.0, the supported range has changed from 1024-1500 to 1024-9216 MTU size for an IPsec site-to site tunnel between two managed devices when Jumbo frames are enabled.
<code>load-balance</code>	Enable VPN load balancing for any tunnel. Disabled
<code>local-fqdn <local_id_fqdn></code>	If the managed device has a dynamic IP address, you must specify the FQDN of the managed device to configure it as a initiator of IKE aggressive-mode.
<code>monitor <monitor-ip> interval <interval_secs></code>	Configure link monitor where <monitor-ip> is IP address of monitor server. interval <interval_secs> is optional interval in seconds.
<code>no</code>	Negates a configured parameter.

Parameter	Description
<pre>peer-cert-dn <peer-dn></pre>	<p>If you are using IKEv2 to establish a site-to-site VPN to a statically addressed remote peer, identify the peer device by entering its certificate subject name in the Peer Certificate Subject Name field.</p>
<pre>peer-fqdn</pre>	<p>For site-to-site VPNs with dynamically addressed peers, specify a FQDN for the managed device:</p> <ul style="list-style-type: none"> ▪ any-fqdn: Any remote FQDN ID ▪ fqdn-id: Unique remote FQDN ID <pre>any-fqdn</pre>
<pre>peer-ip <ipaddr></pre>	<p>If you are using IKEv1 to establish a site-to-site VPN to a statically addressed remote peer, identify the peer device by entering the IP address of the peer gateway.</p> <p>NOTE: If you are configuring an IPsec map for a static-ip managed device with a dynamically addressed remote peer, you must leave the peer gateway set to its default value of 0.0.0.0.</p>
<pre>peer-ipv6 <ipsec-map-peer-ipv6></pre>	<p>If you are using IKEv1 to establish a site-to-site VPN to a statically addressed remote peer, identify the peer device by entering the IPv6 address of the peer gateway.</p> <p>NOTE: If you are configuring an IPsec map for a static-ip managed device with a dynamically addressed remote peer, you must leave the peer gateway set to its default value.</p>
<pre>pre-connect</pre>	<p>Enables or disables pre-connection.</p> <pre>disabled</pre>
<pre>set ca-certificate <cacert-name></pre>	<p>User-defined name of a trusted CA certificate installed on the Mobility Conductor. Use the show crypto-local pki TrustedCA command to display the CA certificates that have been imported into the Mobility Conductor. The CA certificate name must be between 1-64 characters in length.</p> <pre>1-64 characters</pre>

Parameter	Description
<pre>set ikev1-policy <policy-v1-number></pre>	Select an IKEv1 policy for the ipsec-map. Predefined policies are described in the table below.
<pre>set ikev2-policy <policy-v2-number></pre>	Select IKEv2 policy for the ipsec-map. Predefined policies are described in the table below.
<pre>set pfs</pre>	<p>If you enable Perfect Forward Secrecy (PFS) mode, new session keys are not derived from previously used session keys. Therefore, if a key is compromised, that compromised key will not affect any previous session keys. To enable this feature, specify one of the following Perfect Forward Secrecy modes:</p> <ul style="list-style-type: none"> ▪ group1: 768-bit Diffie Hellman prime modulus group. ▪ group2: 1024-bit Diffie Hellman prime modulus group. ▪ group14: 2048-bit Diffie Hellman prime modulus group. ▪ group19: 256-bit random Diffie Hellman ECP modulus group. (For IKEv2 only) ▪ group20: 384-bit random Diffie Hellman ECP modulus group. (For IKEv2 only) <p>disabled</p>
<pre>set security-association lifetime kilobytes <kilobytes></pre>	Configures the lifetime for the security association (SA) in kilobytes. 1000 - 1000000000 kilobytes
<pre>set security-association lifetime seconds <seconds></pre>	Configures the lifetime for the security association (SA) in seconds. 300-86400 seconds 7200 seconds
<pre>set server-certificate <cert-name></pre>	User-defined name of a server certificate installed for the site-to-site IPsec map. Use the <code>show crypto-local pki ServerCert</code> command to display the server certificates that have been imported into the Mobility Conductor. The server certificate name must be between 1-64 characters in length.

Parameter	Description
	1-64 characters
<pre>set transform-set <transform-set-name1> [<transform-set-name2>] [<transform-set-name3>] [<transform-set-name4>]</pre>	<p>Name of the transform set for this IPsec map. One transform set name is required, but you can specify up to four transform sets. Configure transform sets with the <code>crypto ipsec transform-set</code> command.</p> <p>transform</p>
<pre>src-net <ipsec-map-src-net> <ipsec-map-src-mask> any</pre>	IP address and netmask for the source network.
<pre>src-net-ipv6 <ipsec-map-src-net-ipv6> <ipsec-map-src-prefix-len></pre>	IPv6 address and netmask for the source network.
<pre>trusted</pre>	<p>Enables a trusted tunnel.</p> <p>NOTE: The <i>trusted <disable></i> sub-parameter is not supported on the managed device. You must always use the <i>trusted <enable></i> sub-parameter so that the traffic can pass through.</p> <p>disabled</p>
<pre>uplink failover</pre>	<p>Enables or disables uplink failover for site-to-site tunnels.</p> <p>disabled</p>
<pre>version</pre>	<p>Select the IKE version for the IPsec map.</p> <ul style="list-style-type: none"> ▪ v1: IKEv1 ▪ v2: IKEv2 <p>v1</p>
<pre>vlan <ipsec-map-vlan-id></pre>	<p>VLAN ID. Enter 0 for the loopback, and 4095 for cellular.</p> <p>1-4094</p>

Understanding Default IKE policies

ArubaOS includes the following default IKE policies. These policies are predefined and cannot be edited.

Table 7: Default IKE Policy Settings

Policy Name	Policy Number	IKE Version	Encryption Algorithm	Hash Algorithm	Authentication Method	PRF Method	Diffie-Hellman Group
Default protection suite	10001	IKEv1	3DES-168	SHA 160	Pre-Shared Key	N/A	2 (1024 bit)
Default Remote AP Certificate protection suite	10002	IKEv1	AES -256	SHA 160	RSA Signature	N/A	2 (1024 bit)
Default Remote AP PSK protection suite	10003		AES -256	SHA 160	Pre-Shared Key	N/A	2 (1024 bit)
Default Remote AP IKEv2 RSA protection suite	1004	IKEv2	AES -256	SSHA160	RSA Signature	hmac-sha1	2 (1024 bit)
Default Cluster PSK protection suite	10005	IKEv1	AES -256	SHA160	Pre-Shared Key	Pre-Shared Key	2 (1024 bit)
Default IKEv2 RSA protection suite	1006	IKEv2	AES - 128	SHA 96	RSA Signature	hmac-sha1	2 (1024 bit)
Default IKEv2 PSK protection suite	10007	IKEv2	AES - 128	SHA 96	Pre-shared key	hmac-sha1	2 (1024 bit)
Default Suite-B 128bit ECDSA protection suite	10008	IKEv2	AES - 128	SHA 256-128	ECDSA-256 Signature	hmac-sha2-256	Random ECP Group (256 bit)

Policy Name	Policy Number	IKE Version	Encryption Algorithm	Hash Algorithm	Authentication Method	PRF Method	Diffie-Hellman Group
Default Suite-B 256 bit ECDSA protection suite	10009	IKEv2	AES -256	SHA 384-192	ECDSA-384 Signature	hmac-sha2-384	Random ECP Group (384 bit)
Default Suite-B 128bit IKEv1 ECDSA protection suite	10010	IKEv1	AES-GCM-128	SHA 256-128	ECDSA-256 Signature	hmac-sha2-256	Random ECP Group (256 bit)
Default Suite-B 256-bit IKEv1 ECDSA protection suite	10011	IKEv1	AES-GCM-256	SHA 256-128	ECDSA-256 Signature	hmac-sha2-256	Random ECP Group (256 bit)

When using a default IKE (V1 or V2) policy for an IPsec map, the priority number should be the same as the policy number.

Examples

The following commands configures site-to-site VPN between two managed devices:

```
(host) [mynode] (config) #crypto-local ipsec-map sf-chi-vpn 100
src-net 101.1.1.0 255.255.255.0
dst-net 100.1.1.0 255.255.255.0
peer-ip 172.16.0.254
vlan 1
trusted

(host) [mynode] (config) #crypto-local ipsec-map chi-sf-vpn 100
src-net 100.1.1.0 255.255.255.0
dst-net 101.1.1.0 255.255.255.0
peer-ip 172.16.100.254
vlan 1
trusted
```

For a dynamically addressed managed device that initiates IKE Aggressive-mode for Site-Site VPN:

```
(host) [mynode] (config) #crypto-local ipsec-map <ipsec-map-name> <ipsec-
map-number>
src-net <ipsec-map-src-net> <ipsec-map-src-mask>
dst-net <ipsec-map-dst-net> <ipsec-map-dst-mask>
peer-ip <ipaddr>
local-fqdn <local_id_fqdn>
vlan <ipsec-map-vlan-id>
pre-connect {enable|disable}
trusted enable
For the Pre-shared-key:
crypto-local isakmp key <key> address <ipaddr> netmask <mask>
```

For a static IP managed device that responds to IKE Aggressive-mode for Site-Site VPN:

```
(host) [mynode] (config) #crypto-local ipsec-map <ipsec-map-name> <ipsec-
map-number>
src-net <ipsec-map-src-net> <ipsec-map-src-mask>
dst-net <ipsec-map-dst-net> <ipsec-map-dst-mask>
peer-ip 0.0.0.0
peer-fqdn fqdn-id <peer_id_fqdn>
vlan <ipsec-map-vlan-id>
trusted enable
```

For the Pre-shared-key:

```
crypto-local isakmp key <key> fqdn <fqdn-id>
```

For a static IP managed device that responds to IKE Aggressive-mode for Site-Site VPN with One PSK for All FQDNs:

```
(host) [mynode] (config) #crypto-local ipsec-map <ipsec-map-name> <ipsec-
map-number>
src-net <ipaddr> <mask>
peer-ip 0.0.0.0
peer-fqdn any-fqdn
vlan <id>
trusted enable
```

For the Pre-shared-key for All FQDNs:

```
crypto-local isakmp key <key> fqdn-any
```

The following example displays the use of extended scope of address range:

```
(host) [mynode] (config) #crypto-local ipsec-map sparta2vesuvius 100
version v2
set ikev2-policy 10009
peer-ipv6 2004::1
peer-cert-dn "/C=US/ST=HI/L=Camp
Smith/O=PACOM/OU=mil/CN=vesuvius.red1.vpn/emailAddress=admin@pacom.mil"
vlan 202
src-net-ipv6 2012:: 64
dst-net-ipv6 2014:: 64
set transform-set "default-gcm256"
set pfs group20
trusted
set ca-certificate red.ca
set server-certificate sparta.red.vpn
!
```

Related Commands

Command	Description
show crypto-local ipsec-map	Displays current IPsec map configurations for site-to-site VPNs.
crypto_local isakmp disable-ipcomp	Globally disables IP compression on all site-to-site VPNs between Mobility Conductor and managed devices by disabling compression from the master/conductor.

crypto-local isakmp disable-aggressive-mode

crypto-local isakmp disable-aggressive-mode

Description

The command disables the IKEv1 aggressive mode.

The Mobility Conductor-managed device communication, by default, uses IPsec aggressive mode when a PSK is used for authentication. You need to convert Mobility Conductor-managed device communication to certificate-based IPsec authentication before disabling aggressive mode.

Disabling aggressive mode will impact other sessions that use aggressive mode, such as Conductor-local IKE session with PSK.

Example

```
(host) [mynode] (config) #crypto-local isakmp disable-aggressive-mode
```

Related Commands

Command	Description
show crypto-local isakmp	Indicates if aggressive mode is enabled or disabled.

crypto-local isakmp ca-certificate

```
crypto-local isakmp ca-certificate <cacert-name>
```

Description

This command assigns the Certificate Authority (CA) certificate used to authenticate VPN clients. You can assign multiple CA certificates. Use the `show crypto-local isakmp ca-certificate` command to view the CA certificates associated with VPN clients.

Parameter	Description
<cacert-name>	User-defined name of a trusted CA certificate installed on the Mobility Conductor. Use the <code>show crypto-local pki TrustedCA</code> command to display the CA certificates that have been imported into the Mobility Conductor.

Example

This command configures a CA certificate:

```
(host) [mynode] (config) #crypto-local isakmp ca-certificate TrustedCA1
```

Related Commands

Command	Description
show crypto-local isakmp	Displays CA certificates configured for VPN clients.

crypto-local isakmp certificate-group

```
crypto-local isakmp certificate-group server-certificate <server_cert-name> ca-  
certificate <ca_cert-name>
```

Description

The command configures an IKE certificate group for VPN Clients. This feature allows you to create a certificate group so you can access multiple types of certificates on the same Mobility Conductor.

Parameter	Description
server-certificate <server-cert-name>	The IKE server certificate name for VPN clients. 1-64 characters
ca-certificate <ca-cert-name>	The IKE CA certificate for this server certificate. 1-64 characters

Example

This command configures a certificate group that consists of server certificate named "newtest" with the CA certificate "TrustedCA".

```
(host) [mynode] (config) #crypto-local isakmp certificate-group server-  
certificate newtest ca-certificate TrustedCA
```

Related Commands

Command	Description
show crypto-local isakmp	Displays the configured IKE certificate groups for VPN clients.
show crypto-local isakmp	Displays the configured IKE server certificate for VPN clients.

crypto_local isakmp disable-ipcomp

crypto-local isakmp disable-ipcomp

Description

This command disables IP compression on Mobility Conductor. When this hardware-based compression feature is enabled, the quality of unencrypted traffic (such as Skype4b or Voice traffic) is not compromised by increased latency or decreased throughput.

Example

```
(host) [mynode] (config) #crypto-local isakmp disable-ipcomp
```

Related Commands

crypto-local isakmp dpd

```
crypto-local isakmp dpd idle-timeout <idle_sec> retry-timeout <retry_sec> retry-attempts <retry_num>
```

Description

This command configures IKE DPD. DPD is enabled by default for site-to-site VPNs.

Parameter	Description
<code>idle-timeout <idle_sec></code>	Idle timeout, in seconds. 10-3600 seconds 22 seconds
<code>retry-timeout <retry_sec></code>	Retry interval, in seconds. 2-60 seconds 2 seconds
<code>retry-attempts <retry_num></code>	Number of retry attempts. 3-10 3

Example

The following command configures DPD parameters:

```
(host) [mynode] (config) #crypto-local isakmp dpd idle-timeout 60 retry-timeout 3 retry-attempts 5
```

Related Commands

crypto-local isakmp key

```
crypto-local isakmp {key <keystring>|key-hex <keystring>}  
  address <peer-address> netmask <mask>  
  addressv6 <peer-addressv6>  
  fqdn <ike-id-fqdn>  
  fqdn-any
```

Description

This command configures the IKE preshared key for site-to-site VPN. This command configures the IKE preshared key.

Parameter	Description
key <keystring>	IKE preshared key value, between 6-64 characters. To configure a pre-shared key that contains non-alphanumeric characters, surround the key with quotation marks. For example: <code>crypto-local isakmp key "key with spaces" fqdn-any</code> .
key-hex <keystring>	IKE preshared key value, between 6-64 hex-based characters. To configure a pre-shared key that contains non-alphanumeric characters, surround the key with quotation marks.
address <peer-address>	IP address for the preshared key.
netmask <mask>	Netmask for the preshared key.
addressv6 <peer-addressv6>	IPv6 address for the preshared key.
fqdn <ike-id-fqdn>	Configures the PSK for the specified FQDN.
fqdn-any	Configures the PSK for any FQDN.

Example

The following command configures an IKE preshared key for site-to-site VPN:

```
(host) [mynode] (config) #crypto-local isakmp key R8nD0mK3y address

crypto-local isakmp ppk-add

```
crypto-local isakmp ppk-add
  ppk-id <ppk_id>
  ppk-value
  ppk-value-hex
  ppk-value-hex-tpi1
  ppk-value-hex-tpi2
  ppk-value-tpi1
  ppk-value-tpi2
  peer-any
  peer-fqdn
  peer-ip
  peer-ipv6
  peer-mac
```

Description

This command configures the IKE Postquantum Preshared Key (PPK). This command is limited to site-to-site VPNs.

Parameter	Description
ppk-id <ppk_id>	Configures PPK ID. Must be between 3-256 characters.
ppk-value	Configures ppk value.
ppk-value-hex	Configures the PPK Value in hex characters [0-9,a-f,A-F].
ppk-value-hex-tpi1	Configures first part of ppk value for two person integrity in hex characters [0-9,a-f,A-F].
ppk-value-hex-tpi2	Configures second part of ppk value for two person integrity in hex characters [0-9,a-f,A-F].

Parameter	Description
ppk-value-tpi1	Configures first part of ppk value for two person integrity.
ppk-value-tpi2	Configures second part of ppk value for two person integrity.
peer-any	Configures PPK for any Peer.
peer-fqdn	Configures PPK for peer-fqdn.
peer-ip	Configures PPK for peer IP.
peer-ipv6	Configures PPK for peer IPv6.
peer-mac	Configures PPK for peer MAC.

Example

The following command configures an IKE Postquantum Preshared Key(PPK) for a site-to-site VPN:

```
(host)[mynode] #crypto-local isakmp ppk-add
ppk-id                Configure ppk id

(host) [mynode] #crypto-local isakmp ppk-add ppk-id demo
ppk-value             Configure ppk value
ppk-value-hex        Configure the PPK Value in hex characters [0-
9,a-f,A-F]
ppk-value-hex-tpi1   Configure first part of ppk value for two
person integrity in hex characters [0-9,a-f,A-F]
ppk-value-hex-tpi2   Configure second part of ppk value for two
person integrity in hex characters [0-9,a-f,A-F]
ppk-value-tpi1       Configure first part of ppk value for two
person integrity
ppk-value-tpi2       Configure second part of ppk value for two
person integrity

(host) [mynode] #crypto-local isakmp ppk-add ppk-id demo ppk-value
<ppk_value>          Configure ppk value. Must be between 3-256
characters.

(host) [mynode] #crypto-local isakmp ppk-add ppk-id demo ppk-value
demoval peer-
peer-any              Configure PPK for any Peer
peer-fqdn             Configure peer-fqdn
peer-ip               Configure PPK for peer IP
peer-ipv6             Configure PPK for peer IPv6
peer-mac              Configure PPK for peer MAC
```

Command History

ArubaOS 8.10.0.0	Parameter introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	The ppk add command is a global action command that should be configured locally, on an individual managed device to perform a PPK-based exchange.

crypto-local isakmp ppk-delete

```
crypto-local isakmp ppk-delete
  ppk-id <ppk_id>
    peer-any
    peer-fqdn
    peer-ip
    peer-ipv6
    peer-mac
```

Description

This command deletes the IKE Postquantum Preshared Key (PPK). This command is limited to site-to-site VPNs.

Parameter	Description
ppk-id <ppk_id>	Configures PPK ID. Must be between 3-256 characters.
peer-any	Deletes PPK for any peer
peer-fqdn	Deletes peer-fqdn
peer-ip	Deletes PPK for peer IP
peer-ipv6	Deletes PPK for peer IPv6
peer-mac	Deletes PPK for peer MAC

Command History

Version	Modification
ArubaOS 8.10.0.0	Parameter introduced.

crypto-local isakmp xauth

crypto-local isakmp xauth

Description

This command enables IKE XAuth for VPN clients.

The `no crypto-local isakmp xauth` command disables IKE XAuth for VPN clients. This command only applies to VPN clients that use certificates for IKE authentication. If you disable XAuth, then a VPN client that uses certificates will not be authenticated using a username and password. You must disable XAuth for Cisco VPN clients using CAC Smart Cards.

Example

This command disables IKE XAuth for Cisco VPN clients using CAC Smart Cards:

```
(host) [mynode] (config) #no crypto-local isakmp xauth
```

Related Commands

Command	Description
show crypto-local isakmp	Indicates if IKE XAuth is enabled or disabled.

crypto-local pki rcp

```
crypto-local pki rcp <name> [allow-low-assurance-devices|crl-location  
<filename>|enable-ocsp-responder|ocsp-responder-cert <ocsp-responder-cert>|ocsp-  
signer-cert <ocsp-signer-cert>|ocsp-url <ocsp-url>|revocation-check <method1>  
[<method2>]|server-unreachable {revoke-cert|fail-over|allow-cert}]
```

Description

This command specifies the certificates used to sign OCSF for the revocation checkpoint. A revocation checkpoint is automatically created when a TrustedCA or IntermediateCA certificate is imported into Mobility Conductor.

This command allows you to configure the check methods that are used for the given revocation checkpoint. You can configure Mobility Conductor to perform real-time certificate revocation checks using the Online Certificate Status Protocol (OCSP) or traditional certificate validation using the Certificate Revocation List (CRL) client. Refer to the *Certificate Revocation* chapter in the *ArubaOS 8.x User Guide* for more information on how to configure this feature using both the WebUI and CLI.

Parameter	Description
allow-low-assurance-devices	Enables or disables low assurance devices.
crl-location <file>	Location of the CRL that is used for the rcp. The specified CRL filename must be previously imported onto Mobility Conductor before using this option.
enable-ocsp-responder	Enables the OCSP Responder for this revocation checkpoint. The default is disabled.
ocsp-responder-cert <ocsp-responder-cert>	Specifies the certificate that is used to verify OCSP responses. The certificate must be one of the certificate names displayed when the <code>show crypto-local pki OCSPResponderCert</code> command is executed.
ocsp-signer-cert <ocsp-signer-cert>	Specifies the certificate that is used to sign OCSP responses for this revocation checkpoint. The OCSP signer certificate must be previously imported onto Mobility Conductor through the WebUI. The OCSP signer cert can be the same TrustedCA as the checkpoint, a designated OCSP signer certificate issued by the same CA as the checkpoint, or another local trusted authority. If the <code>ocsp-signer-cert</code> is not specified, OCSP responses are signed using the global OCSP signer certificate. If that is not present, an error message is sent out to clients.

Parameter	Description
	<p>NOTE: The OCSP signer certificate (if configured) takes precedence over the global OCSP signer certificate as this is check point specific.</p>
ocsp-url <ocsp-url>	Configures the OCSP Server URL. The URL must be in the form of http://my.responder.com/path . This parameter can contain only one responder URL at time.
revocation-check <method1> [<method2>]	Configures the revocation check methods used for this rcp. Options include: <ul style="list-style-type: none"> ▪ None (default): No revocation checks are performed ▪ CRL: CRL revocation check method ▪ OCSP: OCSP revocation check method You can configure one fallback method.
server-unreachable {revoke-cert fail-over allow-cert}	Configures one of the following methods to use upon failure to connect to the OCSP server: <ul style="list-style-type: none"> ▪ allow-cert: The certificate is considered 'Good' upon failure to establish connection with the OCSP responder server. ▪ fail-over: The certificate revocation is matched against the CRL upon failure to establish connection with the OCSP responder server. ▪ revoke-cert: The certificate is considered 'Revoked' upon failure to establish connection with the OCSP responder server.

Example

This example configures an OCSP client with the OCSP revocation check method and CRL backup method:

```
(host) [mynode] (config) #crypto-local pki rcp CARoot
ocsp-responder-cert RootCA-Ocsp_responder
ocsp-url http://10.4.46.202/ocsp
crl-location file Security1-WIN-05PRNGEKA0-CA-unrevoked.crl
revocation-check ocsp crl
```

Related Commands

Command	Description
crypto-local pki	Configures local certificates, OCSP signer or responder certificates, and Certificate Revocation Lists (CRL). You can also list revocation checkpoints and enable the responder service.
show crypto-local pki	Displays local certificates, OCSP signer or responder certificates, and CRL data and statistics.

Command History

crypto-local isakmp route ipsec

```
crypto-local isakmp route ipsec <route-ipsec-map-name> { subnet <subnet-val> | vlan <vlan-value> }
```

Description

This command configures the subnet route using an IPsec map. The following example configures a subnet route for VLAN 1 using an IPsec map:

```
(host) [mynode] (config) #crypto-local isakmp route ipsec default-local-master-ipsecmap192.190.189.1 vlan 1
```

Parameter	Description
<route-ipsec-map-name>	Name of the IPsec map.
subnet <subnet-val>	subnet route to be pushed.
vlan <vlan-value>	VLAN for which the subnet route is pushed. Each VLAN must be separated by a comma and dash.

Related Commands

Command	Description
show crypto-local ipsec-map	Displays the list of configured IPsec maps.
show vlan	Displays the list of configured VLANs.

crypto-local isakmp sa-cleanup

crypto-local isakmp sa-cleanup

Description

This command enables the cleanup of IKE SAs. You can also remove expired ISAKMP SAs from the Mobility Conductor using this command.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

crypto-local isakmp server-certificate

crypto-local isakmp server-certificate <cert-name>

Description

This command assigns the server certificate used to authenticate the Mobility Conductor or managed device for VPN clients using IKEv1 or IKEv2. This certificate is only for VPN clients and not for site-to-site VPN clients. You can assign separate server certificates for VPN clients using IKEv1 and clients using IKEv2. Use the `show crypto-local isakmp server-certificate` command to view the server certificate associated with VPN clients.

There is a default server certificate installed on Mobility Conductor. However this certificate does not guarantee security for production networks. Best practices is to replace the default certificate with a custom certificate issued for your site or domain by a trusted CA. You can use the WebUI to generate a Certificate Signing Request (CSR) to submit to a CA and then import the signed certificate received from the CA into Mobility Conductor. For more information, see "Managing Certificates" in the *ArubaOS User Guide*.

Parameter	Description
<cert-name>	User-defined name of a server certificate installed on the Mobility Conductor or managed device.

Example

This command configures a server certificate:

```
(host) [mynode] (config) #crypto-local isakmp server-certificate  
MyServerCert
```

Related Commands

Command	Description
show crypto-local isakmp	Displays the server certificates that have been imported into Mobility Conductor.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Config mode on Mobility Conductor.

crypto map global-map

```
crypto map global-map <map-number> ipsec-isakmp {dynamic <dynamic-map-name>|ipsec <ipsec-map-name>}
```

Description

This command configures the default global map. This command identifies the dynamic or IPsec map used as the default global map. If you have not yet defined a dynamic or IPsec map, issue the command [crypto map global-map](#) or [crypto-local ipsec-map](#) to define map parameters.

Parameter	Description
<map-number>	Priority of the map.
ipsec-isakmp	Configures an IPsec map.
dynamic <dynamic-map-name>	Uses a dynamic map.
ipsec <ipsec-map-name>	Uses an IPsec map.

Example

The following command configures the global map with the dynamic map named *dynamic_map_2*.

```
(host) [mynode] (config) #crypto map global-map 2 ipsec-isakmp dynamic
dynamic_map_2
```

The following examples display the use of extended scope of address range:

```
(host) [mynode] (config) #crypto map GLOBAL-IKEV2-MAP 10000 ipsec-isakmp
dynamic default-rap-ipsecmap
(host) [mynode] (config) #crypto map GLOBAL-MAP 10000 ipsec-isakmp dynamic
default-dynamicmap
```

Related Commands

Command	Description
show crypto map	Displays IPsec map configurations.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

crypto pki-import

```
crypto pki-import
  {der|pem|pfx|pkcs12|pkcs7}
  CRL
  IntermediateCA
  OCSPResponderCert
  OCSPSignerCert
  PublicCert
  ServerCert
  TrustedCA
  <name> <filename> [<passphrase>]
```

Description

The command imports certificates for the captive portal feature and enables installation of a CSR for the Captive Portal feature.

Parameter	Description
der	Import the following certificates in .der (Distinguished Encoding Rule) format.
pem	Import a certificate in X.509 .pem (Privacy-enhanced Electronic Mail) format.
pfx	Import a certificate in .pfx (Personal inFormation eXchange) format.
pkcs12	Import a certificate in .p12 format.
pkcs7	Import a certificate in .p7c format.
CRL	Import a Certificate Revocation List.
IntermediateCA	Import an intermediate Certificate Authority (CA) certificate.
OCSPResponderCert	Import an Online Certificate Status Protocol (OCSP) Responder certificate.
OCSPSignerCert	Import an OCSP Signer certificate.
PublicCert	Import a public certificate.
ServerCert	Import a server certificate.
TrustedCA	Import a trusted CA certificate.
<name> <filename> <passphrase>	<ul style="list-style-type: none">▪ name- Name of the certificate.▪ filename- Original imported file name of the certificate.

Parameter	Description
	<ul style="list-style-type: none"> ▪ passphrase– Optional passphrase for storing the certificate private key. <p>NOTE: The passphrase is not stored in the system. It is used during the import process only.</p>

Example

The following command installs a server certificate in **.der** format.

```
(host) [md] #crypto pki-import der ServerCert cert_20
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

crypto-local pki

```
crypto-local pki
  allow-low-assurance-devices
  CRL <name> <filename>
  global-ocsp-signer-cert
  IntermediateCA <name> <filename>
  OCSPResponderCert <certname> <filename>
  OCSPSignerCert <certname> <filename>
  PublicCert <name> <filename>
  rcp <name>
  ServerCert <name> <filename>
  service-ocsp-responder {enable|disable}
  TrustedCA <name> <filename>
```

Description

This command configures a local certificate, OCSP signer or responder certificate, and Certificate Revocation List (CRL). You can also list revocation checkpoints and enable the responder service.

This command lets you configure the Mobility Conductor to perform real-time certificate revocation checks using the Online Certificate Status Protocol (OCSP) or traditional certificate validation using the Certificate Revocation List (CRL) client. Refer to the *Certificate Revocation* chapter in the *ArubaOS 8.x User Guide* for more information on how to configure this feature using both the WebUI and CLI.

Parameter	Description
allow-low-assurance-devices	Enables or disables low assurance devices.
CRL	Specifies a Certificate Revocation list. Validation of the CRL is done when it imported through the WebUI (requires the CA to have been already present). CRLs can only be imported through the WebUI.
<name>	Name of the CRL.
<filename>	Original imported filename of the CRL.
global-ocsp-signer-cert	Specifies the global OCSP signer certificate used to sign OCSP responses if there is no checkpoint-specific OCSP signer certificate present. If the ocp-signer-cert is not specified, OCSP responses are signed using the global OCSP signer certificate. If this is not present, an error message is sent out to clients. NOTE: The OCSP signer certificate (if configured) takes precedence over the global OCSP signer certificate as this is checkpoint-specific.

Parameter	Description
IntermediateCA	Configures an intermediate CA certificate.
<name>	Name of the intermediate CA certificate.
<filename>	Original imported filename of the CRL.
OCSPResponderCert	Configures an OCSP responder certificate.
<certname>	Name of responder certificate.
<filename>	Original imported filename of the responder certificate.
OCSPSignerCert	Configures an OCSP signer certificate.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.
PublicCert	Public key of a certificate. This allows an application to identify an exact certificate.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.
rcp <name>	Specifies the revocation checkpoint. A revocation checkpoint is automatically created when a TrustedCA or IntermediateCA certificate is imported on the Mobility Conductor. See crypto-local pki rcp for more details.
ServerCert	Configures a server certificate. This certificate must contain both a public and private key (the public and private keys must match). You can import a server certificate in either PKCS12 or x509 PEM format; the certificate is stored in x509 PEM DES encrypted format on the Mobility Conductor.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.
service-ocsp-responder	Enables or disables the OCSP responder service. The default is disabled . To enable this option, a CRL must be configured for this revocation checkpoint, as this is the source of revocation information in the OCSP responses.
TrustedCA	Configures a trusted CA certificate. This can be either a root CA or intermediate CA. Aruba encourages (but does not require) an intermediate CA's signing CA to be the Mobility Conductor itself.
<certname>	Name of the signer certificate.
<filename>	Original imported filename of the signer certificate.

Example

The following example configures the Mobility Conductor as an OCSF responder:

```
(host) [mynode] (config) #crypto-local pki service-ocsp-responder
(host) [mynode] (config) #crypto-local pki rcp CARoot
ocsp-signer-cert RootCA-Ocsp_signer
crl-location file Security1-WIN-05PRGNGEKAO-CA-unrevoked.crl
enable-ocsp-responder
```

Related Commands

Command	Description
crypto-local pki rcp	Specifies the certificates that are used to sign OCSF responses for this revocation check point
show crypto-local pki	Displays local certificates, OCSF signer or responder certificates, and CRL data and statistics.

Command History

Version	Modification
ArubaOS 8.2.0.0	The <code>allow-low-assurance-devices</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

crypto dynamic-map

```
crypto dynamic-map <dynamic-map-name> <dynamic-map-number>
  disable
  no ...
  set pfs {group1|group2|group14|group19|group20}
  set security-association lifetime kilobytes <kilobytes>
  set security-association lifetime seconds <seconds>
  set transform-set <name1> [[<name2>] [<name3>] [<name4>]]
  version {v1|v2}
```

Description

This command configures a new or existing dynamic map. Dynamic maps enable IPsec SA negotiations from dynamically addressed IPsec peers. Once you have defined a dynamic map, you can optionally associate that map with the default global map using the command [crypto map global-map](#).

Parameter	Description
<dynamic-map-name>	Name of the map.
<dynamic-map-number>	Priority number of the map. 1-10000 10000
disable	Disables the dynamic map.
no	Negates a configured parameter.
set pfs	Enables Perfect Forward Secrecy (PFS) mode. Use one of the following: <ul style="list-style-type: none">▪ group1: 768-bit Diffie Hellman prime modulus group.▪ group2: 1024-bit Diffie Hellman.▪ group14: 2048-bit Diffie Hellman.▪ group19: 256-bit random Diffie Hellman ECP modulus group.▪ group20: 384-bit random Diffie Hellman ECP modulus group. group1
set security-association lifetime seconds <seconds>	Lifetime for the security association (SA) in seconds. 300-86400 7200
set security-association	Lifetime for the security association (SA) in kilobytes.

Parameter	Description
<code>lifetime kilobytes <kilobytes></code>	1000 - 1000000000
<code>set transform-set <name1> [[<name2>] [<name3>] [<name4>]]</code>	Name of the transform set for this dynamic map. You can specify up to four transform sets. You configure transform sets with the crypto ipsec transform-set command. transform
<code>version {v1 v2}</code>	Version of IKE protocol used to set up a security association (SA) in the IPsec protocol suite: <ul style="list-style-type: none"> ▪ v1:IKEv1 ▪ v2: IKEv2 v1

Example

The following command configures a dynamic map:

```
(host) [mynode] (config) #crypto dynamic-map dmap1 100
set pfs group2
set security-association lifetime seconds 300
```

Related Commands

Command	Description
show crypto dynamic-map	Displays IPsec dynamic map configurations.

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	The group19 and group20 PFS options requires the Advanced Cryptography (ACR) license. All other parameters are available in the base operating system.	Config mode on Mobility Conductor.

crypto ipsec

```
crypto ipsec
  mtu <max-mtu>
  rekey interval <ipsec-rekey-interval>
  transform-set <transform-set-name>
    esp-3des {esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
    esp-aes128 {esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
    esp-aes128-gcm
    esp-aes192 {esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
    esp-aes256 {esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
    esp-aes256-gcm
    esp-des {esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
    esp-null {esp-md5-hmac|esp-null-hmac|esp-sha-hmac}
```

Description

This command configures IPsec parameters. Define the Maximum Transmission Unit (MTU) size allowed for network transmissions using IPsec security, and create or edit transform sets that define a specific encryption and authentication type.

Parameter	Description
mtu <max-mtu>	Configure the IPsec Maximum Transmission Unit (MTU) size. <ul style="list-style-type: none">▪ Range—1024-2500▪ Default —1500 NOTE: Starting from ArubaOS 8.10.0.0, the supported range has changed from 1024-1500 to 1024-2500 MTU size.
rekey interval <ipsec-rekey-interval>	Configure IPsec rekey interval. the value can be between 300 to 7200 seconds. The no crypto ipsec rekey interval parameter restores the rekey time to default value.
transform-set <transform-set-name>	Configure a transform set.
transform-set <transform-set-mtu>	Create or modify a transform set.
esp-3des	Use ESP with 168-bit 3DES encryption.
esp-aes128	Use ESP with 128-bit AES encryption.
esp-aes128-gcm	Use ESP with 128-bit AES-GCM encryption.
esp-aes192	Use ESP with 192-bit AES encryption.

Parameter	Description
<code>esp-aes256</code>	Use ESP with 256-bit AES encryption.
<code>esp-aes256-gcm</code>	Use ESP with 256-bit AES-GCM encryption.
<code>esp-des</code>	Use ESP with 56-bit DES encryption.
<code>esp-null</code>	Use ESP with NULL encryption. Supported with only IKEv1.
The following fields are common to the parameters listed in the command definition:	
<code>esp-md5-hmac</code>	Use ESP with the MD5 (HMAC variant) authentication algorithm.
<code>esp-null-hmac</code>	Use ESP with no authentication. This option is not recommended.
<code>esp-sha-hmac</code>	Use ESP with the SHA (HMAC variant) authentication algorithm.

Example

The following command configures 3DES encryption and MD5 authentication for a transform set named **set2**:

```
(host) [mynode] (config)# crypto ipsec transform-set set2 esp-3des esp-md5-hmac
```

Command History

Release	Modification
ArubaOS 8.7.0.0	The <code>rekey</code> parameter was introduced.
ArubaOS 8.1.0.0	The <code>esp-null</code> transform-set parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	The <code>esp-aes128-gcm</code> and <code>esp-aes56-gcm</code> transform-set parameters require the Advanced Cryptography (ACR) license. All other parameters are available in the base OS.	Config mode on Mobility Conductor.

crypto isakmp

```
crypto isakmp
  block-aruba-ca {enable|disable}
  clear-map
  eap-passthrough {eap-gtc|eap-mschapv2|eap-peap|eap-tls}
  groupname <name>
  initiate-route
  key {key <keystring>|key-hex <keystring-hex>}
  packet-dump {peer <pktdump-peer-ip> | peer-v6 <pktdump-peer-ipv6>}
  policy
  rekey
  udpencap-behind-natdevice {enable|disable}
```

Description

This command configures Internet Key Exchange (IKE) parameters for the Internet Security Association and Key Management Protocol (ISAKMP). Use this command to configure the IKE pre-shared key, set the EAP authentication method for IKEv2 clients using EAP user authentication, and enable source NAT if the IP addresses of clients need to be translated to access the network.

Parameter	Description
block-aruba-ca	Configures the managed device to accept or reject Aruba-certified clients: <ul style="list-style-type: none">▪ enable: Rejects Aruba-certified client certificates and uses custom certificates instead▪ disable: Accepts Aruba-certified client certificates
clear-map	Clear crypto maps that are created by auto-passcode command but not used now.
eap-passthrough	Select one of the following authentication types for IKEv2 user authentication using EAP. <ul style="list-style-type: none">▪ eap-gtc: EAP-GTC authentication method▪ eap-mschapv2: EAP-MSCHAPv2 authentication method▪ eap-peap: EAP-PEAP authentication method▪ eap-tls: EAP-TLS authentication method <p>NOTE: The eap-passthrough parameter allows IKE module to forward the EAP messages between VPN client and external authentication server during tunnel establishment. It is recommended to have a secure channel between ArubaOS and external authentication server to protect sensitive data.</p>

Parameter	Description
groupname <name>	Configures the IKE Aggressive group name. Aggressive-mode IKE is a 3-packet IKE exchange that does not provide identity-protection, but is faster, because fewer messages are exchanged.
initiate-route	Initiate a route to fpapps.
sa	Security Associations
peer <source-ip>	choose an IKE peer.
key {key <keystring> key-hex <keystring-hex>}	Configures the IKE preshared key, which must be 6-64 characters in length: <ul style="list-style-type: none"> ▪ key: Configures the IKE preshared key using text-based characters. ▪ key-hex: Configures the IKE preshared key using hex-based characters (0-9, a-f, A-F).
packet-dump	Enable the packet dump feature for testing.
peer <pktdump-peer-ip>	Configure peer filter for packet dump.
peer-v6 <pktdump-peer-ipv6>	Configure ipv6 peer filter for packet dump.
policy	Configure an IKE policy. [1 - 10015] - 1 highest priority. (priority > 10000 is reserved for default policies)
rekey	Configure IKE rekey interval. The <code>no crypto isakmp rekey interval</code> parameter restores the rekey time to default value.
udpencap-behind-natdevice	Configures NAT-T if the managed device is behind an NAT device (for Windows VPN Dialer only): <ul style="list-style-type: none"> ▪ enable: Enables NAT-T ▪ disable: Disables NAT-T

Example

The following command configures an ISAKMP peer IP address and subnet mask. After configuring an ISAKMP address and netmask, you will be prompted to enter the IKE preshared key.

```
(host) [mynode] (config) #crypto isakmp address 10.3.14.21 netmask 255.255.255.0
Key:*****Re-Type Key:*****
```

crypto isakmp policy

```
crypto isakmp policy <priority>
  authentication {pre-share|rsa-sig|ecdsa-256|ecdsa-384}
  disable
  enable [bypass|secret]
  encryption {3DES|AES128|AES192|AES256|DES}
  group {1|2|14|19|20}
  hash {md5|sha|sha1-96|sha2-256-128|sha2-384-192}
  prf {PRF-HMAC-MD5|PRF-HMAC-SHA1|PRF-HMAC-SHA256|PRF-HMAC-SHA384}
  lifetime <seconds>
  no disable
  version {v1|v2}
```

Description

This command configures Internet Key Exchange (IKE) policy parameters for the Internet Security Association and Key Management Protocol (ISAKMP). To define settings for a ISAKMP policy, issue the command `crypto isakmp policy <priority>` then press **Enter**. The CLI will enter **config-isakmp** mode, which allows you to configure the policy values.

Parameter	Description
<priority>	Specifies a number from 1 to 10,000 to define a priority level for the policy. The higher the number, the higher the priority level.
authentication	Configures the IKE authentication method: <ul style="list-style-type: none">▪ pre-share: Preshared key▪ rsa-sig: RSA signatures▪ ecdsa-256: ECDSA-256-bit signatures▪ ecdsa-384: ECDSA-384-bit signatures
disable	Disables the IKE policy.
enable [bypass secret]	Enables the IKE policy using the bypass or secret. Bypass prompts for the enable mode login and password. Secret prompts for the enable password.
encryption	Configures the IKE encryption algorithm: <ul style="list-style-type: none">▪ 3DES: 168-bit 3DES-CBC encryption algorithm▪ AES128: 128-bit AES-CBC encryption algorithm▪ AES192: 192-bit AES-CBC encryption algorithm▪ AES256: 256-bit AES-CBC encryption algorithm▪ DES: 56-bit DES-CBC encryption algorithm
group	Configures the IKE Diffie Hellman group: <ul style="list-style-type: none">▪ 1: 768-bit Diffie Hellman prime modulus group. This is the

Parameter	Description
	default group setting. <ul style="list-style-type: none"> ▪ 2: 1024-bit Diffie Hellman prime modulus group ▪ 14: 2048-bit Diffie Hellman DDH prime modulus group ▪ 19: 256-bit random Diffie Hellman ECP modulus group ▪ 20: 384-bit random Diffie Hellman ECP modulus group
hash	Configures the IKE hash algorithm: <ul style="list-style-type: none"> ▪ md5: MD5 (HMAC variant) hash algorithm ▪ sha: SHA1-160 (HMAC variant) hash algorithm ▪ sha1-96: SHA1-96 (HMAC variant) hash algorithm ▪ sha2-256-128: SHA2-256-128 (HMAC variant) hash algorithm ▪ sha2-384-192: SHA2-384-192 (HMAC variant) hash algorithm
prf	Sets one of the following pseudo-random function (PRF) values for an IKEv2 policy: <ul style="list-style-type: none"> ▪ PRF-HMAC-MD5 (default): MD5 (HMAC variant) PRF ▪ PRF-HMAC-SHA1: SHA1-160 (HMAC variant) PRF ▪ PRF-HMAC-SHA256: SHA2-256 PRF ▪ PRF-HMAC-SHA384: SHA2-384 PRF
lifetime <seconds>	Specifies the lifetime of the IKE security association (SA), from 300 - 86400 seconds.
no disable	Disables the IKE policy.
version	Specifies the version of IKE protocol for the IKE policy: <ul style="list-style-type: none"> ▪ v1: IKEv1 ▪ v2: IKEv2

Example

The following command configures the RSA signature authentication method for the given IKE policy:

```
(host) [mynode] (config) #crypto isakmp policy 1
(host) [mynode] (config-isakmp) #authentication rsa-sig
Key:*****Re-Type Key:*****
```

crypto pki

```
crypto pki
  csr {ec|rsa}
    key_len <key_val>
    curve-name <key_val>
    common_name <common_val>
    country <country_val>
    state_or_province <state>
    city <city_val>
    organization <organization_val>
    unit <unit_val>
    email <email_val>
  expirycheck
  export ca-cert pem self-signed {console|<filename>}
```

Description

This command generates a Certificate Signing Request (CSR) for the captive portal feature. Use this command in enable mode to generate a CSR for the Captive Portal feature or to see all managed devices certificates that are expiring.

Displays the CSR output by entering the command `show crypto pki csr`.

Parameter	Description
<code>csr {ec rsa}</code>	Generate a certificate signing request. Execute the <code>show crypto pki csr</code> command to view output again. This parameter has the following sub-parameters: <ul style="list-style-type: none">▪ <code>ec</code>- Generate a certificate signing request with an Elliptic Curve (EC) key.▪ <code>rsa</code>- Generate a certificate signing request with a Rivest, Shamir and Adleman (RSA) key.
<code>key_len <key_val></code>	Generate a certificate signing request with an RSA key with one of the following supported RSA key lengths: <ul style="list-style-type: none">▪ 1024▪ 2048▪ 4096
<code>curve-name <key_val></code>	Generate a certificate signing request with an EC key, with one of the following EC types: <ul style="list-style-type: none">▪ <code>secp256r1</code>▪ <code>secp384r1</code>
<code>common_name <common_val></code>	Specify a common name, e.g., <code>www.yourcompany.com</code> .

Parameter	Description
country <country_val>	Specify a country name, e.g., US or CA.
state_or_province <state>	Specify the name of a state or province.
city <city_val>	Specify the name of a city.
organization <organization_val>	Specify the name of an organization unit, e.g., sales.
unit <unit_val>	Specify a unit value, e.g. EMEA.
email <email_val>	Specify an email address, in the format name@mycompany.com.
expirycheck	Run an expiry check on all certificates on the managed device.
export	Export self signed PKI CA certificate in .pem format.

Example

The following command configures a CSR for a user with the email address *jdoe@example.com*.

```
(host) [md] #crypto pki csr key 1024 common_name www.example.lcom country US state_or_province ca city Sunnyvale organization engineering unit pubs email jdoe@example.com

database synchronize

```
database synchronize
  captive-portal-custom
  period <minutes>
```

Description

This command configures the Mobility Conductor to synchronize the database with a standby or backup Mobility Conductor. This command should be executed from the **/mm** node hierarchy. The command takes effect immediately. Use the `database synchronize period` command in config mode to configure the interval for automatic database synchronization.

Parameter	Description
<code>captive-portal custom</code>	Synchronizes custom captive portal files.
<code>period</code>	Configures the interval for automatic database synchronization.
<code><minutes></code>	Interval, in minutes. Range is 1 — 25200 minutes.

Example

The following command causes the database on the active Mobility Conductor to synchronize with the standby in 25 minute intervals.

```
(host) [mynode] (config) #database synchronize period 25
```

Related Commands

Command	Description
database-synchronize	This command synchronizes the Mobility Conductor database with a standby or backup Mobility Conductor.

datapath

```
datapath {coredump | dns-cache periodic-flush <interval> <threshold> | energy-efficiency}
```

Description

This command configures datapath options.

Parameter	Description
coredump	Generates a coredump, which is a copy of the datapath memory, in the event that the datapath times out. This copy is saved in the system memory.
dns-cache periodic-flush	Configures time period to check if the dns iplist table has reached the configured threshold level.
<interval>	Time interval to check the dns-cache-table threshold. Range: 1 to 24 hours
<threshold>	Threshold limit after which the dns-cache-table will be cleared. Range: 50 to 99 percentage
energy-efficiency	Minimizes idle CPU spinning.

Example

The following command enables datapath coredump:

```
(host) [mynode] (config) #datapath coredump
```

Command History

Release	Description
ArubaOS 8.5.0.7	The dns-cache periodic-flush <interval> <threshold> parameter was introduced.

database-synchronize

database-synchronize

Description

This command synchronizes the Mobility Conductor database with a standby or backup Mobility Conductor.

This command should be executed from the enable mode of the Mobility Conductor and takes effect immediately. If a peer is not configured, the Mobility Conductor displays an error message **Cannot start database synchronization: peer is not configured.**

Example

The following command invokes the database on the active Mobility Conductor to synchronize with the standby:

```
(host) [mynode] #database-synchronize
```

Related Commands

dds trace

```
dds trace {receive|transmit} [channel <channel>|peer <A.B.C.D>|peerv6 <X:X:X:X::X>]
```

Description

This command configures trace events.

Parameter	Description
receive	Configures trace receiving events.
transmit	Configures trace transmitting events.
channel	GSM channel for tracing.
<channel>	Name of GSM channel.
peer	DDS peer.
<A.B.C.D>	Peer IP address.
peerv6	DDS IPv6 peer.
<X:X:X:X::X>	Peer IPv6 address.

Example

The following command configures a trace receiving event for the radio GSM channel. Use the `show gsm channel` command to view the list of available GSM channels.

```
(host) [mynode] (config) #dds trace receive channel radio peer 10.20.22.17
```

delete

```
delete
  filename <filename>
  ssh-host-addr <ipaddr>
  ssh-known-hosts
```

Description

This command deletes a file or RSA signature entry from flash. To prevent running out of flash file space, you should delete files that you no longer need. The `copy scp` command creates RSA signatures whenever it connects to a new host. These host signatures are stored in the flash file system.

Parameter	Description
filename	<p>Name of the file to be deleted.</p> <p>Filenames can be specified in the below formats:</p> <ul style="list-style-type: none">▪ To specify filename listed in 'dir' command <code>delete filename <file-name></code>▪ To specify filename listed in 'dir flash' with complete path <code>delete filename <flash_file_path/file-name></code>▪ To delete multiple files with similar filenames, use 'asterisk' in the end <p>For example, <code>delete filename test*</code>: all file names beginning with test will be deleted from /flash/config folder.</p> <p>For example, <code>delete filename <flash_file_path>/test*</code>: all filenames beginning with test will be deleted from <flash_file_path> folder.</p> <p>NOTE: Only files listed in <code>dir</code> and <code>dir flash</code> can be deleted.</p>
ssh-host-addr	Deletes the entry stored in flash for the RSA host signature created when you run the <code>copy scp</code> command.
ssh-known -hosts	Deletes all entries stored in flash for the RSA host signatures created when you run the <code>copy scp</code> command.

Example

The following command deletes a file:

```
(host) [mynode] #delete filename december-config-backup.cfg
```

The following command deletes an RSA signature entry from flash:

```
(host) [mynode] #delete ssh-host-addr 10.100.102.101
```

The following command deletes all RSA signature entries from flash:

```
(host) [mynode] #delete ssh-known-hosts
```

delete-wired-blacklist-user / delete-wired-denylist-user

delete-wired-blacklist-user / delete-wired-denylist-user mac <macaddr>

Description

This command deletes a wired user from blacklist/denylist table.

Parameter	Description
mac <macaddr>	MAC address, in the format xx:xx:xx:xx:xx:xx.

Example

The following command deletes a wired user from blacklist/denylist table:

```
(host) [mynode] #delete-wired-blacklist-user 00:0b:86:f0:05:60
(host) [mynode] #delete-wired-denylist -user 00:0b:86:f0:05:60
```

dir

```
dir
  date
  flash
  name
  search
  size
  usb:
```

Description

This command displays a list of files stored in the flash file system.

Use this command to view the system files associated with the Mobility Conductor. To view the system file associated with the managed device, login to the Mobility Conductor and initiate a telnet or SSH session to the managed device.

Parameter	Description
date	Sort the directory contents by date
flash	list the /flash directory contents
name	Sort the directory contents by name
search	Filter the directory contents by keyword
size	Sort the directory contents by size
usb:	Displays the files in the external USB. NOTE: This parameter can be executed for managed devices that have an USB port.

Output from this command includes the following:

- The first column contains ten place holders that display the file permissions.
 - First place holder: Displays - for a file or **d** for directory.
 - Next three place holders: Display file owner permissions: **r** for read access, **w** for write access permissions, **x** for executable.
 - Following three place holders: Display member permissions: **r** for read access or **x** for executable.
 - Last three place holders: Display non-member permissions: **r** for read access or **x** for executable.
- The second column displays the number of links the file has to other files or directories.

- The third column displays the file owner.
- The fourth column displays group/member information.
- The remaining columns display the file size, date and time the file was either created or last modified, and the file name.

Example

The following command displays the files currently residing on the system flash:

```
(host) [mynode] #dir
```

The following is sample output from this command:

```
-rw-r--r-- 1 root root 9338 Nov 20 10:33 class_ap.csv
-rw-r--r-- 1 root root 1457 Nov 20 10:33 class_sta.csv
-rw-r--r-- 1 root root 16182 Nov 14 09:39 config-backup.cfg
-rw-r--r-- 1 root root 14174 Nov 9 2005 default-backup-11-8-05.cfg
-rw-r--r-- 1 root root 16283 Nov 9 12:25 default.cfg
-rw-r--r-- 1 root root 22927 May 25 12:21 default.cfg.2016-05-25_20-21-38
-rw-r--r-- 2 root root 19869 May 9 12:20 default.cfg.2016-05-09_12-20-22
```

disaster-recovery

```
disaster-recovery
  off
  on
```

Description

This command enables or disables disaster recovery mode on the managed device.

This command is used to recover operations on a managed device that has inherited an incorrect configuration from the Mobility Conductor and can no longer communicate with the Mobility Conductor. When disaster-recovery is enabled, the configuration inherited from the Mobility Conductor can be modified locally on the managed device. When disaster-recovery mode is disabled, the managed device will synchronize its configuration with the Mobility Conductor and any local configuration changes on the managed device will be overwritten.

An example could be a configuration change on the Mobility Conductor that has modified VLAN or port information on the managed device that breaks the IPSEC connection between them. An administrator can enable disaster-recovery mode and correct the configuration on the managed device to restore connectivity to the Mobility Conductor.

Parameter	Description
off	Disables disaster recovery mode.
on	Enables disaster recovery mode.

Example

The following command enables the disaster recovery mode in the managed device:

```
(host-md) #disaster-recovery on
*****
Entering disaster recovery mode
*****
(DR-Mode) [mm] #
```

disable-crc-workaround

disable-crc-workaround

Description

Starting from ArubaOS 8.6.0.7, users can issue the `disable-crc-workaround` command when port flaps of the uplink switch are not detected by the Mobility Master. This command dumps all the PHY register data like alarms, warnings, signal strength and hence, will be helpful for debugging.

It is to be noted that when this configuration is enabled, the CRC workaround will be initiated only when the uplink switch shuts down and come up and not when the the device is stable.

Example

```
(host) [mynode] (config) #disable-crc-workaround
```

Command History

Release	Description
ArubaOS 8.7.1.1	Command introduced.

Command Information

disable-whitelist-sync / disable-allowlist-sync

disable-whitelist-sync / disable-allowlist-sync

Description

This command disables whitelist/allowlist synchronization with managed devices and it is enabled by default.

Once the entries are synchronized across all controllers, issue the `disable-whitelist-sync / disable-allowlist-sync` command to disable synchronization. Configuring this parameter reduces the number of database queries on Mobility Conductor.

Enabling whitelist/allowlist database synchronization may increase database process CPU utilization on Mobility Conductor if there is a large number of entries and managed devices terminating on the Mobility Conductor.

Example

The following command disables whitelist/allowlist synchronization:

```
(host) [mynode] (config) #disable-whitelist-sync / disable-allowlist-sync
```

Command History

Release	Description
ArubaOS 8.9.0.0	The following terminologies are updated: <ul style="list-style-type: none">▪ All instances of <code>master</code> have been replaced with <code>conductor</code>.▪ All instances of <code>whitelist</code> have been replaced with <code>allowlist</code>.
ArubaOS 8.0.0.0	Command introduced.

dot1x

```
dot1x
  eap-frag-mtu <eapfragmtu>
  high-watermark <1-32000>
  stm-throttling percent <10-80>
```

Use this command only under the supervision of Aruba support.

Description

Use this command under the guidance of Aruba support to configure the maximum and minimum thresholds for the table that contains 802.1X sessions.

Parameter	Description
<code>eap-frag-mtu <eapfragmtu></code>	Enables fragmentation of EAP packets in non-term mode towards EAP server
<code>high-watermark</code>	The maximum entries in the Active table. When the number of entries in the Active table reaches the High Water Mark value, new requests are queued on the Pending table. 1-32000 entries
<code>stm-throttling-percent <10-80></code>	Enables STM throttling when the total entries in the Pending table are greater than (stm-throttling percent) * (high watermark). The default STM throttling percent is 50%. 10-80%

Example

The following command sets the **High Water Mark** value to 200 entries:

```
(host) [mynode] (config) #dot1x high-watermark 200
```

Related Commands

Command	Description
<code>show dot1x watermark</code>	Displays information about the table that contains 802.1X sessions.

dot1x-transactions-monitor

```
dot1x-transactions-monitor
  start
  stop
```

Description

This command starts or stops the display of the rate statistics using the `show dot1x-transactions-monitor` command. After setting the interval and duration of the rate statistics, enable the start option to start the rate statistics in the `show dot1x-transactions-monitor` command output. To stop the running statistics, manually enter the stop command in the `dot1x-transactions-monitor` command.

Parameter	Description
<start>	Starts the rate statistics in the <code>show dot1x-transactions-monitor</code> command output.
<stop>	Stops the rate statistics in the <code>show dot1x-transactions-monitor</code> command output.

Example

The following command sets the interval and duration of stats for a 802.1X user:

```
(host) [mynode] (config) #dot1x-transactions-monitor 15 55
```

Related Commands

Command	Description
dot1x-transactions-monitor set	Sets the rate statistics interval duration and the total duration of a 802.1X transaction.

downloadable-role-delete

downloadable-role-delete STRING

Description

This command deletes a corrupted role downloaded from ClearPass Policy Manager.

You can delete a downloadable role under the following conditions:

- If no user references the role.
- If the role is in **Complete** or **Incomplete** state.

Parameter	Description
STRING	Downloadable role name.

Example

The following command deletes the *abc_profile-3023-8* user role:

```
(host) [mynode] #downloadable-role-delete abc_profile-3023-8
```

dpi

dpi

```
app <string> ports [tcp <tportlist>][udp <uportlist>]
appcategory <string> <categoryID>
custom-app <appname> <appid> [appcategory|http {hostname-param <hostname> uri-
  param <uri>|referrer-param <referrer>}|https {common-name <commonname>}]
global-bandwidth-contract {app <string>[downstream|upstream] [kbits
  <256..2000000>|mbits <1..2000>}|appcategory <string>[downstream |upstream]
  [kbits|mbits <value>]}
```

Description

This command configures DPI and the global bandwidth contract for an application or application category for the AppRF feature, and allows network administrators to define custom applications for use with DPI features.

You can configure bandwidth contracts to limit application and application categories on an application or global level.

Applications and application categories can be user-defined. Issue the `show dpi custom-app all` command to view all user-defined (custom) applications and the `show dpi application category user-defined all` command to view all user-defined categories.

Parameter	Description
app <string>	Name of the application for which you want to enable DPI. For a complete list of supported applications, issue the command <code>show dpi application all</code> .
tcp <tportlist>	Enables DPI on the selected TCP port(s). You can enter a range of ports (for example, 80-85), or enter multiple individual port numbers separated by a comma (or example, 40,44,48).
udp <uportlist>	Enables DPI on the selected TCP port(s). You can enter a range of ports (for example, 80-85), or enter multiple individual port numbers separated by a comma (or example, 40,44,48).
appcategory	Configures an application category.
<string>	Name of the application category. Allowed characters include: <ul style="list-style-type: none">▪ a-z▪ 0-9▪ "_" and "-"
<categoryid>	Sets a unique category ID.

Parameter	Description
	1-32
custom-app	Creates a new custom application.
<appname>	Name of the custom application. Allowed characters include: <ul style="list-style-type: none"> ▪ a-z ▪ 0-9 ▪ " " ▪ -
<appID>	Sets a unique application ID. 1-64
appcategory	Application category name.
http	Creates a new HTTP-based custom application
hostname-param <hostname> uri-param <uri>	Specifies a hostname and URI to create an application based upon that server name and URI
referrer-param <referrer>	A referrer is the URL of a webpage from which a link was followed. Specify a referrer to create a HTTP referrer-based application.
https	Create a new HTTPS-based custom application
common-name <commonname>	Specify a CN to create an application based on it.
global-bandwidth-contract	Configures the global bandwidth contract for an application or application category. 256 kbps-2 gbps
app <string>	Name of the application. For a complete list of supported applications, issue the command <code>show dpi application all</code> . Applications can also be user-defined. Issue the <code>show dpi custom-app all</code> command to view all user-defined (custom) applications.
appcategory <string>	Name of the application category. For a complete list of supported application categories, issue the command <code>show dpi application category all</code> . Application categories can also be user-defined. Issue the <code>show dpi application category user-defined all</code> command to view all user-defined (custom) categories.
downstream	Bandwidth contract to downstream traffic.

Parameter	Description
upstream	Bandwidth contract to upstream traffic.
kbits <value>	Specifies bandwidth in kbits per second. 256-2000000 kbits
mbits <value>	Specifies bandwidth in mbits per second. 1-2000 mbits

Example

The following command configures a global bandwidth contract for downstream traffic:

```
(host) [md] (config) #dpi global-bandwidth-contract appcategory web
downstream kbits 10000
```

Use the following commands to view global bandwidth contract configuration outputs:

```
(host) [md] #show dpi global-bandwidth-contract all
(host) [md] #show dpi global-bandwidth-contract application name
(host) [md] #show dpi global-bandwidth-contract appcategory name
```

Related Commands

Command	Description
show dpi	Displays the applications and application categories that are configured for Deep-Packet Inspection.

dump-collection-profile

```

dump-collection-profile
  clone <source>
  dump-auto-uploading-profile
  dynamic-pcap-interval <dynamic-pcap-interval>
  NO
  server-ip <server-ip>
  server-password <server-password>
  server-path <server-path>
  server-port <server-port>
  server-username <server-username>
  system-dump-enable
  transfer-enable
  transfer-mode {scp | tftp | USB-Transfer}

```

Description

This command configures a dump collection profile.

Parameter	Description
clone <source>	Copy data from specified dump collection profile.
dump-auto-uploading-profile	Configures the dump auto uploading profile.
dynamic-pcap-interval <dynamic-pcap-interval>	Specify the dynamic pcap collection interval in minutes. This value can be from 0 to 30 minutes. To disable the dynamic pcap collection, set this interval value to 0.
NO	Delete command
server-ip <server-ip>	Specify IP address of the server for dump collection.
server-password <server-password>	Specify the server password for dump collection.
server-path <server-path>	Specify the server file path for dump collection.
server-port <server-port>	Server Port for Dump Collection
server-username <server-username>	Server Username for Dump Collection
system-dump-enable	Enable Collection of System Dump in case of AP Crash

Parameter	Description
transfer-enable	Enable transfer of collected file.
transfer-mode {scp tftp USB-Transfer}	Specify one of the following mode to transfer dump files: <ul style="list-style-type: none"> ■ scp: Dump files will be transferred using SCP. ■ TFTP: Dump files will be transferred using TFTP. ■ USB-Transfer: Dump files will be copied to connected USB device in case of a crash.

The following command configures the dump collection profile:

```
(host) [mynode] (config) #dump-collection-profile default
(host) [mynode] (Dump collection profile "default") #
clone                               Copy data from another Dump collection profile
dump-auto-uploading-profile         Dump auto uploading profile
dynamic-pcap-interval              Dynamic pcap collection interval [mins]. Range
0-30. 0:disabled
no                                  Delete Command
server-ip                          Server IP(v4/v6) for Dump Collection
server-password                    Server Password for Dump Collection
server-path                        Server File Path for Dump Collection
server-port                        Server Port for Dump Collection
server-username                    Server Username for Dump Collection
system-dump-enable                 Enable Collection of System Dump in case of AP
Crash
transfer-enable                    Enable Transfer Collected File
transfer-mode                       Configure Dump Transfer Mode
```

The following command configures the dump auto uploading profile.

```
(host) [mynode] (config) #dump-auto-uploading-profile test
(host) [mynode] (Dump Auto Uploading profile "test") #
clone                               Copy data from another Dump Auto Uploading profile
no                                  Delete Command
nss-dump-enable                    Enable Collect nssddr, nssimem Dump Files
radio-dump-enable                  Enable Collect imem, q6mem, QCN9000 Dump Files
```

Command History

Release	Modification
ArubaOS 8.11.1.0	The dump-auto-uploading-profile parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

eject usb

```
eject usb: slot {all|<slotno>}
```

Description

This command ejects an external USB device from the managed device. Use this command to safely remove an external USB device. This command should be executed from the managed device only.

Parameter	Description
all	Eject all external USB devices.
<slotno>	Enter optional slot number to eject the USB device.

Example

This command ejects all external USB devices from the managed device.

```
(host-md) #eject usb: slot all
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Enable mode on Managed Device.

encrypt

encrypt {disable|enable}

Description

This command allows passwords and keys to be displayed in plain text or encrypted. Certain commands, such as `show crypto isakmp key`, display configured key information. Use the `encrypt` command to display the key information in plain text or encrypted.

Parameter	Description
disable	Passwords and keys are displayed in plain text.
enable	Passwords and keys are displayed in encrypted form. enabled

Example

The following command allows passwords and keys to be displayed in plain text:

```
(host) [mynode] #encrypt disable
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

esi group

```
esi group <group_inst> [ping <attributes>|server <server>]
```

Description

This command configures an ESI group. Use the `show esi groups` command to view ESI group information.

Parameter	Description
<group_inst>	Specifies the ESI group configuration.
no	Delete the command.
ping <ping>	Specifies a set of ping checking attributes. Only one set is allowed.
server <server>	Adds or removes a server from the ESI group.

Example

The following command sets up the ESI group named “fortinet”:

```
(host) [md] (config) #esi group fortinet
ping default
server forti_1
```

Related Commands

Command	Description
show esi groups	Displays ESI group information.

All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

esi parser domain

```
esi parser domain <domain-name>  
  peer <peer-ip>  
  server <ipaddr>
```

Description

This command configures an ESI syslog parser domain. The ESI parser is a generic syslog parser that accepts syslog messages from external third-party appliances, such as anti-virus gateways, content filters, and intrusion detection systems. It processes syslog messages according to user-defined rules and takes configurable actions on the corresponding system users.

ESI servers (see [esi server on page 622](#)) are configured into domains to which ESI syslog parser rules (see [esi parser rule on page 616](#)) are applied.

Parameter	Description
<domain-name>	ESI parser domain name.
no	Delete the command.
peer <peer-ip>	Specifies the IP address of an another managed device in this domain, which is notified when the user cannot be found locally. This command is required only when multiple managed devices share a single ESI server.
server <ipaddr>	Specifies the IP address of the ESI server to which the managed device listens.

Example

The following commands configure a virus syslog parser domain named “fortinet” that contains the ESI server “forti_1” with a trusted IP address:

```
(host) [md] (config) #esi parser domain fortinet  
server 10.168.172.3
```

Related Commands

Command	Description
show esi parser	Displays information about the ESI parser domains.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

esi parser rule

```
esi parser rule <rule_name>
  condition <string>
  domain <word>
  enable
  match {ipaddr <string>|mac <string>|user <string>}
  no
  position <1-32>
  set {denylist/blacklist|role <word>}
  test {msg <syslog>|file <filename>}
```

Description

This command creates or changes an ESI syslog parser rule. The user creates an ESI rule by using characters and special operators to specify a pattern that uniquely identifies a syslog message. This “condition” defines the type of message and the ESI domain to which this message pertains. The rule contains three major fields:

- **Condition:** The pattern that uniquely identifies the syslog message type.
- **User:** The username identifier. It can be in the form of a name, MAC address, or IP address.
- **Action:** The action to take when a rule match occurs.

Once a condition match occurs, no further rule-matching will be made. For the matching rule, only one action can be defined.

For more details on the character-matching operators, repetition operators, and expression anchors used to defined the search or match target, refer to the *External Services Interface* chapter in the *ArubaOS 8.x User Guide* .

Use the `show esi parser rules` command to show ESI parser rule information. Use the `show esi parser stats` command to show ESI parser rule statistical information.

Parameter	Description
<rule-name>	Name of the ESI parser rule.
condition <string>	Specifies the REGEX (regular expression) pattern that uniquely identifies the syslog.
domain <word>	(Optional) Specifies the ESI syslog parser domain to which this rule applies. If not specified, the rule matches with all configured ESI servers.
enables	Enables this rule. NOTE: The condition, user match, and set action parameters must be configured before the rule can be enabled.

Parameter	Description
	Disabled
match	Specifies the user identifier to match, where ipaddr , mac , and user take a REGEX pattern that uniquely identifies the user.
ipaddr <string>	Matches using the client IP address.
mac <string>	Matches using the client MAC address.
user <string>	Matches using the client user name.
no	Negates any configured parameter.
position	Specifies the rule's priority position. 1–32; 1 highest
set	Specifies the action to take. NOTE: The role entity should be configured before it is accepted by the ESI rule.
blacklist/denylist	Blocks the user.
role <word>	Changes the user role.
test	Tests the regular expression output configured in the <code>esi parser rules</code> command.
msg <syslog>	Tests the rule against a syslog message.
file <filename>	Tests the rule against a syslog file.

Examples

The following command sets up the Fortigate virus rule named "forti_rule." This rule parses the virus detection syslog scanning for a condition match on the log_id value (log_id=) and a match on the IP address (src=).

```
(host) [md] (config) #esi parser rule forti_rule
condition "log_id=[0-9]{10}[ ]"
match ipaddr "src=(.*)[ ]"
set blacklist/denylist
domain fortinet
enable
```

In this example, the corresponding ESI expression is:

```
< Sep 26 18:30:02 log_
id=0100030101 type=virus subtype=infected src=1.2.3.4 >
```

The following example of the test command tests a rule against a specified single syslog message:

```
(host) [md] (config) #esi parser rule test msg "26 18:30:02 log_
id=0100030101 type=virus subtype=infected src=1.2.3.4"

< 26 18:30:02 log_id=0100030101 type=virus subtype=infected src=1.2.3.4 >
=====
Condition:      Matched with rule "forti_rule"
User:          ipaddr = 1.2.3.4
=====
```

The following example of the test command tests a rule against a file named test.log, which contains several syslog messages:

```
(host) [md] (config) #esi parser rule test file test.log

< Sep 26 18:30:02 log_
id=0100030101 type=virus subtype=infected src=1.2.3.4 >
=====
Condition:      Matched with rule "forti_rule"
User:          ipaddr = 1.2.3.4
=====

< Oct 18 10:43:40 cli[627]: PAPI_
Send: To: 7f000001:8372 Type:0x4 Timed out. >
=====
Condition:      No matching rule condition found
=====

< Oct 18 10:05:32 mobileip
[499]: <500300> <DEBUG> |mobileip| Station 00:40:96:a6:a1:a4,

esi ping

```
esi ping <ping_inst>
  frequency <frequency_inst>
  no
  retry-count <retry-count_inst>
  timeout <timeout_inst>
```

Description

This command specifies the ESI ping health check configuration. Use the [show esi ping](#) command to show ESI ping information.

Parameter	Description
<ping_inst>	Specifies the ping health check configuration.
frequency <frequency_inst>	Specifies the ping frequency, in seconds. 1-65535 seconds 5 seconds
no	Negates any configured parameter.
retry-count <retry-count_inst>	Specifies the ping retry count. 1-65535 2
timeout <timeout_inst>	Specifies the ping timeout, in seconds. 1-65535 seconds 2 seconds

Example

The following command specifies the ping health check attributes.

```
(host) [md] (config) #esi ping default
frequency 5
retry-count 2
timeout 2
```

Related Commands

Command	Description
<code>show esi ping</code>	Displays ESI ping information.

esi server

```
esi server <server_inst>
  dport <tcp-udp-port>
  mode {bridge|nat|route}
  no
  trusted-ip-addr <trusted-ip-addr_inst> [health-check]
  trusted-port <slot/port> |
  untrusted-ip-port <untrusted-ip-addr_inst> [health-check]
  untrusted-port <slot/port>
```

Description

This command configures an ESI server.

Parameter	Description
<server_inst>	Specifies the ESI server configuration.
dport <tcp-udp-port>	Specifies the NAT destination TCP or UDP port.
mode	Specifies the ESI server mode of operation: <ul style="list-style-type: none">▪ bridge: ESI server operates as a transparent bridge▪ nat: NAT destination addresses for the ESI server▪ route: ESI server operates as a router
no	Negates any configured parameter.
trusted-ip-addr <trusted-ip-addr_inst>	Specifies the server IP address on the trusted network. As an option, you can also enable a health check on the specified address
trusted-port <slot/port>	Specifies the port connected to the trusted side of the ESI server. The interface must be in <slot>/<port> format.
untrusted-ip-addr <untrusted-ip-addr_inst>	Specifies the server IP address on the untrusted network. As an option, you can also enable a health check on the specified address
untrusted-port <slot/port>	Specifies the port connected to the untrusted side of the ESI server. The interface must be in <slot>/<port> format.

Example

The following command specifies the ESI server attributes:

```
(host) [md] (config) #esi server forti_1
mode route
```

```
trusted-ip-addr 10.168.172.3
untrusted-ip-addr 10.168.171.3
```

est

```
est profile <profile_name>
  arbitrary-label <arbitrary-label>
  arbitrary-label-enrolment <arbitrary-label-enrolment>
  arbitrary-label-reenrolment <arbitrary-label-reenrolment>
  challenge-password <challenge-password>
  clone <source>
  csr_attribute <attribute-type>
  organizational-unit-name <name>
  server-host <server-host>
  server-port <server-port>
  trustanchor-name <trustanchor-name>
  username <username>
  password <password>
  no..
```

Description

This command configures an EST profile on the controller. This configuration is then pushed to the AP on successful enrollment. Use this command to configure an EST profile on the controller.

Parameter	Description
profile <profile_name>	Denotes the profile name of the EST profile.
arbitrary-label <arbitrary-label>	Sets an arbitrary label for the EST URI to distinguish it from the other EST profiles running on the EST server.
arbitrary-label-enrolment <arbitrary-label-enrolment>	Sets an arbitrary enrollment label for EST URI.
arbitrary-label-reenrolment <arbitrary-label-reenrolment>	Sets an arbitrary re-enrollment label for EST URI.
challenge-password <challenge-password>	Sets a challenge password used in CSR.
clone <source>	Name of an existing EST profile from which parameter values are copied.

Parameter	Description
csr_attribute	Configures the csr attribute type. Default is 2048 bit RSA with SHA 256 digest.
organizational-unit-name <name>	Sets the organizational unit name. String length: 1 to 63
server-host <server-host>	Denotes the IPv4 address or the hostname of the EST server.
server-port <server-port>	Indicates the port value of the EST server. The default value is 443.
trustanchor-name <trustanchor-name>	Denotes the server's trustanchor.
username <username>	Sets an username for the EST Client.
password <password>	Sets a password for the EST Client.
no..	Deletes the configuration.

Example

The following command configures an EST profile:

```
(host) [mynode] (config)# est profile est-new
(host) [mynode] (est profile "est-new" )# server-host 10.15.33.232
(host) [mynode] (est profile "est-new" )# server-port 443
(host) [mynode] (est profile "est-new" )# arbitrary-label /ca:2
(host) [mynode] (est profile "est-new" )# arbitrary-label-enrolment /ca:7
(host) [mynode] (est profile "est-new" )# arbitrary-label-reenrolment /ca:7
(host) [mynode] (est profile "est-new" )# csr_attribute ECDSAprime384r1_
with_SHA384
(host) [mynode] (est profile "est-new" )# challenge-password pass123
(host) [mynode] (est profile "est-new" )# trustanchor-name trust456
```

Command History

Release	Modification
ArubaOS 8.8.0.0	The <code>csr_attribute</code> parameter was introduced.
ArubaOS 8.6.0.0	The following parameters were introduced: <ul style="list-style-type: none"> ▪ <code>arbitraty label enrolment</code> ▪ <code>arbitrart label reenrolment</code> ▪ <code>organizational unit name</code> ▪ <code>username/password</code>
ArubaOS 8.2.0.0	Command introduced.

Command Information

execute

```
execute chat_script <chat_script_cmd>
```

Description

This command executes the specified CLI command.

Parameter	Description
chat_script <chat_script_cmd>	Specify the custom or pre_set chat command to be executed.

Example

This command executes the chat command modem-em12-status.

```
(host-md) #execute chat_script modem-em12-status
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

exit

exit

Description

This command exits the current CLI mode.

Upon entering this command in a configuration submode, you are returned to the configuration mode. Upon entering this command in configuration mode, you are returned to the enable mode. Upon entering this command in enable mode, you are returned to the user login.

Example

The following sequence of `exit` commands return the user from the interface configuration submode to the user login:

```
(host) [mynode] (config-if) #exit
(host) [mynode] (config) #exit
(host) [mynode] #exit
User:
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

export

```
export gap-db <filename>
```

Description

This command exports the global AP database to the specified file. This command is intended for system troubleshooting. You should run this command only when directed to do so by an Aruba support representative.

The global AP database resides on Mobility Conductor and contains information about known APs on all managed devices in the system. You can view the contents of the global AP database with the `show ap database` command.

Parameter	Description
<filename>	Name of the file to which the global AP database is exported.

Example

The following command exports the global AP database to a file:

```
(host) [mynode] #export gap-db global-ap-db
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .

file syncing profile

```
file syncing profile
  file-syncing-enable
  no
  sync-time <sync-time>
```

Description

This command allows the user to configure the file syncing profile. This command enables or disables the file syncing. Additionally, the time between syncs can be configured as part of the file syncing profile.

Parameter	Description
file-syncing-enable	Enables file syncing on the managed device. Enabled
no	Negates any configured parameter.
sync-time <sync-time>	Configures the time between file syncs, in minutes. 30 -180 minutes 30 minutes

Example

The following example shows how to enable the file syncing:

```
(host) [md] (config) #file syncing profile
(host) (File syncing profile) #file-syncing-enable
```

Related Commands

Command	Description
show file syncing profile	Displays the configured file syncing profiles.

Description

This command configures global firewall options on the managed device.

Parameter	Description
allow-tri-session	Allows three-way session when performing destination NAT. This option should be enabled when the managed device is not the default gateway for wireless clients and the default gateway is behind the managed device. This option is typically used for captive portal configuration. Disabled
amsdu	Aggregated Medium Access Control Service Data Units (AMSDU) packets are dropped if this option is enabled. Disabled
app-perf-monitoring	Enables app performance monitoring. This parameter is used to measure the time taken for an application to respond.
<pre> attack-rate arp <1-16384> {blacklist/denylist drop} cp <1-16384> grat-arp <1-16384> {blacklist/denylist drop} ping <1-16384> session <1-16384> tcp-syn <1-16384> </pre>	<p>Sets rates which, if exceeded, can indicate a denial of service attack.</p> <ul style="list-style-type: none"> arp: Monitor/police ARP attack (non Gratuitous ARP). 100 cp: Monitor/police control processor attack. grat-arp: Monitor/police Gratuitous ARP attack. 50 ping: Monitor ping attack. session: Monitor IP session attack. tcp-syn: Monitor TCP SYN attack.

Parameter	Description
	1-16384 is the number of requests per 30 seconds.
<code>bwcontracts-subnet-broadcast</code>	Applies bw contracts to local subnet broadcast traffic.
<code>cp-bandwidth-contract</code>	Configures bandwidth contract traffic rate limits, in packets per second, to prevent denial of service attacks.
<code>debug-route</code>	Enable route or route-cache specific IP tracing in datapath.
<code>disable</code>	Disable route or route-cache debugging in datapath
<code>ipv4 <ipv4-addr></code>	Specify IPv4 route or route-cache address.
<code>ipv6 <ipv6-addr></code>	Specify IPv6 route or route-cache address.
<code>deny-inter-user-bridging</code>	Prevents the forwarding of Layer2 traffic between wired or wireless users. You can configure user role policies that prevent Layer3 traffic between users or networks but this does not block Layer2 traffic. This option can be used to prevent traffic, such as Appletalk or IPX from being forwarded. If enabled, traffic (all non-IP traffic) to untrusted port or tunnel is also blocked. Disabled
<code>deny-inter-user-traffic</code>	Denies downstream traffic between users in a wireless network (untrusted users) by disallowing layer2 and layer3 traffic. This parameter does not depend on the <code>deny-inter-user-bridging</code> parameter being enabled or disabled. Disabled
<code>deny-needfrag-df-gre-xmit-icmp</code>	Drops IP packets with DF bit set when packet length is greater than GRE tunnel MTU and an ICMP error message is sent. Disabled

Parameter	Description
deny-needfrag-df-gre	Drops IP packets with DF bit set when packet length is greater than GRE tunnel MTU and an ICMP error message is not sent. disabled
deny-needfrag-df-ipsec	Drops IP packets with DF bit set when packet length is greater than IPsec tunnel MTU and an ICMP error message is sent. Enabled
deny-needfrag-gre-xmit-icmp	Drops IP packets when packet length is greater than GRE tunnel MTU and an ICMP error message is sent. Disabled
deny-needfrag-gre	Drops IP packets when packet length is greater than GRE tunnel MTU and an ICMP error message is not sent. Disabled
deny-source-routing	Disallows forwarding of IP frames with source routing with the source routing options set. Disabled
dhcp-perf monitoring	Enables DHCP performance monitoring. This parameter is used to measure the time taken for a DHCP exchange. Disabled
disable-ftp-server	Disables the FTP server on the managed device. Enabling this option prevents FTP transfers. Enabling this option could cause APs to not boot up. You should not enable this option unless instructed to do so by an Aruba representative. disabled
dpi	Enables DPI. Disabled
drop-ip-fragments	When enabled, all IP fragments are dropped. You should not enable this option unless instructed to do so by an Aruba representative.

Parameter	Description
	Disabled
enable-bridging	Enables bridging when the managed device is in factory default. Disabled
enable-gre-inner-pkt-frag	Enables fragmenting inner IP frames when packet length is greater than GRE tunnel MTU. Disabled
enable-per-packet-logging	Enables logging of every packet if logging is enabled for the corresponding session rule. Normally, one event is logged per session. If you enable this option, each packet in the session is logged. You should not enable this option unless instructed to do so by an Aruba representative, as doing so may create unnecessary overhead on the managed device. Disabled
enable-port-packet-drop-logging	Enables port packet logging. If enabled, the dropped frames are logged. Disabled
enable-stateful-icmp	Enables stateful ICMP processing. This parameter create sessions for ICMP errors and denies unidirectional replies. Disabled
enforce-tcp-handshake	Prevents data from passing between two clients until the three-way TCP handshake has been performed. This option should be disabled when you have mobile clients on the network as enabling this option will cause mobility to fail. You can enable this option if there are no mobile clients on the network. Disabled
enforce-tcp-sequence	Enforces the TCP sequence numbers for all packets. Disabled

Parameter	Description
<code>gre-call-id-processing</code>	Creates a unique state for each PPTP tunnel. Do not enable this option unless instructed to do so by a technical support representative. Disabled
<code>imm-fb</code>	Immediately free buffers on managed device. Do not enable this option unless instructed to do so by a technical support representative. Disabled
<code>ip-classification</code>	Enables IP reputation / geolocation classification.
<code>ipsec-mark-mgmt-frames</code>	This parameter marks management frames.
<code>jumbo</code>	Enables jumbo frames processing. Disabled
<code>local-valid-users</code>	Adds only IP addresses, which belong to a local subnet, to the user-table. Disabled
<code>log-icmp-error</code>	Logs received ICMP errors. You should not enable this option unless instructed to do so by a customer support representative. Disabled
<code>macast-red</code>	Configures multicast random drop parameters. Disabled
<code>maxp-inv <maxp-inv></code>	Inverse mark probability instance. 1-255
<code>min-th <minimum threshold></code>	Configures minimum threshold. 1-99
<code>max-th <maximum threshold></code>	Configures maximum threshold. 1-99
<code>optimize-dad-frames</code>	Reduce flooding of IPv4 Gratuitous ARPs/IPv6 Duplicate Address Detection frames onto wireless clients. Enabled

Parameter	Description
prevent-dhcp-exhaustion	<p>Enable check for DHCP client hardware address against the packet source MAC address. This command checks the frame's source-MAC against the DHCPv4 client hardware address and drops the packet if it does not match. Enabling this feature prevents a client from submitting multiple DHCP requests with different hardware addresses, thereby preventing DHCP pool depletion.</p> <p>Disabled</p>
prohibit-arp-spoofing	<p>Detects and prohibits arp spoofing. When this option is enabled, possible arp spoofing attacks are logged and an SNMP trap is sent.</p> <p>Disabled</p>
prohibit-ip-spoofing	<p>Detects IP spoofing (where an intruder sends messages using the IP address of a trusted client). When this option is enabled, source and destination IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent.</p> <p>Enabled in IPv4, disabled in IPv6</p>
prohibit-ip-spoofing-all	<p>Detects ARP spoofing, when an intruder sends ARP using the IP and MAC addresses of a known user. When this option is enabled, additional check for the user route cache entry is performed. If the route cache entry is not found or if found, but the route cache entry MAC does not match with the sender MAC in ARP frame, then, the frame is marked as spoof. The IP spoofing attacks are logged and an SNMP trap is sent. If the Prohibit IP Spoofing option is enabled, the controller denies all the traffic from the client using an IP address that is used by another client that has an entry in the user table. This option does not allow multiple MAC addresses to use the same IP address.</p> <p>Disabled</p>
prohibit-rc-update	<p>This option prohibits route-cache update on user add.</p>

Parameter	Description
	Disabled
prohibit-rst-replay	Closes a TCP connection in both directions if a TCP RST is received from either direction. You should not enable this option unless instructed to do so by an Aruba representative. Disabled
session-idle-timeout	Time, in seconds, that a non-TCP session can be idle before it is removed from the session table. You should not modify this option unless instructed to do so by an Aruba representative. 16-300 16
session-spread	Enables counter CPU to perform encryption. Applicable to 7200 Series controllers only Disabled
session-tunnel-fib	Enable session tunnel-based forwarding. NOTE: Best practices is to enable this parameter only during maintenance window or off-peak production hours. On the M3, this parameter only enables tunnel-based forwarding, as session-based forwarding does not apply to this platform.
shape-mcast	Enables multicast optimization and provides excellent streaming quality regardless of the amount of VLANs or IP IGMP groups that are used. Disabled
stall-crash	Triggers datapath crash on stall detection. Applies to the to 7200 Series managed device only. Enabled
track-spoof	If enabled, detects spoof in datapath. Disabled

Parameter	Description
voip-qos-trusted	<p>Prioritizes the RTP traffic based on the DSCP value set by the end user device.</p> <p>NOTE: On enabling, all UCC based ALGs will be disabled.</p> <p>Disabled</p>
voip-wmm-voip-content-enforcement	<p>If traffic to or from the user is inconsistent with the associated QoS policy for voice, the traffic is reclassified to best effort and data path counters incremented. This parameter requires the PEFNG license.</p> <p>Disabled</p>
web-cc	<p>Enables web content classification for all HTTP traffic. Once enabled, ArubaOS enforces ACLs and bandwidth policies associated with web content categories or reputation levels.</p> <p>NOTE: On enabling web-cc, the web-cc feature usage information will be sent to Aruba at every 7 days interval.</p> <p>Disabled</p>
web-cc-cache-miss-drop	<p>Issue this command to allow the managed device to drop any packets that do not match any web content category or reputation levels in the managed device's internal web content cache.</p> <p>Disabled</p>
wireless-bridge-aging	<p>Issue this command to prevent the aging of wireless client associated with AP.</p> <p>Enabled</p>

Example

The following command disallows forwarding of non-IP frames between users:

```
(host)[/md] (config) #firewall deny-inter-user-bridging
```

Release	Description
ArubaOS 8.11.0.0	Default rate added for <code>attack-rate arp</code> parameter.
ArubaOS 8.6.017 and 8.7.1.9	The deny-needfrag-df-ipsec parameter was introduced.
ArubaOS 8.6.0.9	The <code>prohibit-rc-update</code> parameter is added.
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.8.0.0	The <code>session-spread</code> and <code>prohibit-ip-spoof-all</code> parameters were added.
ArubaOS 8.7.0.0	The following parameters were introduced: <ul style="list-style-type: none">▪ <code>enable-gre-inner-pkt-frag</code>▪ <code>deny-needfrag-df-gre-xmit-icmp</code>▪ <code>deny-needfrag-df-gre</code>▪ <code>deny-needfrag-gre-xmit-icmp</code>▪ <code>deny-needfrag-gre</code>
ArubaOS 8.4.0.0	The <code>voip-qos-trusted</code> parameter was added.
ArubaOS 8.2.0.0	The <code>wireless-bridge-aging</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system except the <code>voip-wmm-voip-content-enforcement</code> parameter which requires the PEFNG license.	Config mode on Mobility Conductor.

firewall cp

```
firewall cp
  ipv4|ipv6 deny|permit <ip-addr><ip-mask>|any|{host <ip-addr>} proto{<ip-protocol-
  number> ports <start port number><end port
  number>}|ftp|http|https|icmp|snmp|ssh|telnet|tftp [bandwidth-contract
  <name>|<pbwm>]
  no...
```

Description

This command creates whitelist/allowlist session ACLs. Whitelist/allowlist ACLs consist of rules that explicitly permit or deny session traffic from being forwarded or not to the managed device. This prohibits traffic from being automatically forwarded to the managed device if it was not specifically denied in a blacklist/denylist. The maximum number of entries allowed in the whitelist/allowlist is 64.

Parameter	Description
ipv4 ipv6	Specifies ipv4 or ipv6.
deny permit	Specifies the entry to reject (deny) on the session ACL whitelist/allowlist. Specifies an entry that is allowed (permit) on the session ACL whitelist/allowlist.
<ip-addr><ip-mask>	IPv4/IPv6 source address and source mask.
any	Specifies any IPv4 or IPv6 source address.
host <ip-addr>	Indicates a specific IPv4 or IPv6 source address.
proto	Specify one of the following protocols used by the session traffic: <ul style="list-style-type: none">▪ ftp▪ http▪ https▪ icmp▪ scmp▪ ssh▪ telnet▪ tftp
bandwidth-contract <name>	Specify the name of a bandwidth contract. configures a bandwidth contract traffic rate, which can then be associated with a whitelist/allowlist session ACL

Parameter	Description
position <prio>	Specify filter position. Default is last position. 1 is first position.
IP protocol number	Specifies the IP protocol number that is permitted or denied. 1-255
start port	Specifies the starting port, in the port range, on which session traffic is running. 1-65535
end port	Specifies the last port, in the port range, on which session traffic is running. 1-65535
<pbwm>	Bandwidth rate in packets/seconds. 1-64000

Example

The following command creates a whitelist/allowlist ACL that allows on with the source address as 10.10.10.10 and the source mask as 2.2.2.2. The protocol is FTP and the bandwidth contract name is mycontract.

```
(host) [/md] (config-fw-cp) #ipv4 permit 10.10.10.10 2.2.2.2 proto ftp
bandwidth-contract name mycontract
```

The following command creates a whitelist/allowlist ACL entry that denies traffic using protocol 2 on port 5000 from being forwarded to the managed device:

```
(host) [/md] (config-fw-cp) #deny proto 6 ports 5000 6000
```

The following example configures a bandwidth contract named "cp-rate" with a rate of 100 pps.

```
(host) [/md] (config) #cp-bandwidth-contract cp-rate pps 100
```

Related Commands

firewall-visibility

```
firewall-visibility
  blk-session
  feed <sort-by-bssid>
  no ...
```

Description

This command configures policy enforcement firewall visibility feature.

When you enable this feature, the **Firewall Monitoring** page on the **Dashboard** tab of the WebUI displays the summary of all sessions in the managed device aggregated by users, devices, destinations, applications, WLANs, and roles.

Parameter	Description
blk-session	Enables or disables blocked session logging and display.
feed <sort-by-bssid>	Enables or disables sorting of firewall visibility sessions based on the BSSID. Disabled

Example

The following command enables firewall visibility.

```
(host) [mynode] (config) #firewall-visibility
```

The following command enables grouping of firewall visibility sessions based on the same BSSID.

```
(host) [mynode] (config) #firewall-visibility feed sort-by-bssid
```

firewall cp-bandwidth-contract

```
firewall cp-bandwidth-contract {arp-traffic|auth|ike <rate>|ippkt-err|l2-  
other|oflow|route|sessmirr|trusted-mcast|trusted-ucast  
|untrusted-mcast|untrusted-ucast | vrrp}
```

Description

This command configures bandwidth contract traffic rate limits, in packets per second, to prevent denial of service attacks.

Parameter	Description
arp-traffic	Specifies the arp traffic rate limit in packets per second. Is applied as a multiples of 32 in datapath. 1-65535 pps 976 pps
auth	Specifies the traffic rate limit that is forwarded to the authentication process. 1-65535 pps 976 pps
ike <rate>	Specifies the traffic rate limit from IKE to CP, in packets per second. 1-65535 pps 976 pps
ippkt-err	Specifies the rate limit error IP in packets per-second (Applied as a multiple of 32 in datapath) 1-65535 pps
l2-other	Specifies the traffic rate limit for L2 protocol and L2 special handling traffic. 1-65535 pps 976 pps
oflow mdns	Specifies the rate limit Openflow MDNS in packets per-second (Applied as a multiple of 32 in datapath) 1-65535 pps
route	Specifies the traffic rate limit that needs ARP requests. 1-65535 pps 976 pps

Parameter	Description
sessmirr	Specifies the session mirrored traffic forwarded to the managed device. 1-65535 pps 976 pps
trusted-mcast	Specifies the trusted multicast traffic rate limit. 1-65535 pps 1953 pps
trusted-ucast	Specifies the trusted unicast traffic rate limit. 1-98304 pps
untrusted-mcast	Specifies the untrusted multicast traffic rate limit. 1-65535 pps 1953 pps
untrusted-ucast	Specifies the untrusted unicast traffic rate limit. 1-65535 pps 9765 pps
vrrp	Specifies the rate limit of VRRP traffic routed to the control plane. 1-65535 pps 9765 pps

Example

The following command disallows forwarding of non-IP frames between users:

```
(host) [/md] (config) #firewall deny-inter-user-bridging
```

gateway health-check

```
gateway health-check  
  <interval> <threshold>
```

Description

This command configures the default gateway health check for the managed device.

The managed device is rebooted if the default gateway becomes unreachable.

Parameter	Description
<interval>	Health check interval. 30-600 seconds
<threshold>	Number of missed pings before the managed device reboots. 3-64

Example

The following command configures the default gateway health check with an interval of 60 seconds and threshold of 10:

```
(host) [/md] (config) #gateway health-check 60 10
```

Related Commands

Command	Description

gps

```
gpe service profile <profile-name>
  clone <source>
  dynamic-model
  enable
  no
```

Description

This command configures the GPS profile.

Parameter	Description
clone	Copy data from another GPS Service Profile.
<source>	Specify the name of GPS Service Profile to copy.
dynamic-model	Configure dynamic model of GPS.
airbornev1	Set the dynamic model of the GPS to airborne with 1g acceleration.
airbornev2	Set the dynamic model of the GPS to airborne with 2g acceleration.
airbornev4	Set the dynamic model of the GPS to airborne with 4g acceleration.
automotive	Set the dynamic model of the GPS to automotive.
bike	Set the dynamic model of the GPS to bike.
pedestrian	Set the dynamic model of the GPS to pedestrian.
portable	Set the dynamic model of the GPS to portable.
sea	Set the dynamic model of the GPS to sea.
stationary	Set the dynamic model of the GPS to stationary.
wrist	Set the dynamic model of the GPS to wrist-worn watch.
enable	Enable the GPS profile.
no	Disable the GPS profile.

Related Commands

guest-access-email

```
guest-access-email
  smtp-port <port>
  smtp-server
  no
```

Description

This command configures the SMTP server that is used to send guest emails. Guest emails are generated when a guest user account is created or when the Guest Provisioning user sends a guest user account email at a later time.

As part of the guest provisioning feature, the `guest-access-email` command allows you to set up the SMTP port and server that process guest provisioning email. This email process sends email to either the guest or the sponsor whenever a guest user account is created or when the Guest Provisioning user manually sends email from the **Guest Provisioning** page.

Parameter	Description
<code>smtp-port <port></code>	Identifies the SMTP port through which the guest-access email is sent. 1-65535 25
<code>smtp-server <IP-Address></code>	The SMTP server to which the guest-access email is sent.
<code>no</code>	Deletes the command configuration

Example

The following command creates a guest-access email profile and sends guest user email through SMTP server IP address 1.1.1.1 on port 25:

```
(host) [mynode] (config) #guest-access-email
(host) [mynode] (Guest-access Email Profile) #
(host) [mynode] (Guest-access Email Profile) #smtp-port 25
(host) [mynode] (Guest-access Email Profile) #smtp-server 1.1.1.1
```

Related Commands

Command	Description
show guest-access-email	Displays the guest access email profile configuration.

ha

```
ha group-membership <group-membership>
ha group-profile <profile-name>
  clone <source>
  controller <ip> role {active|dual|standby}
  controller-v6 <ipv6> role {active|dual|standby}
  ha-on-bkup-lms
  heartbeat
  heartbeat-interval <heartbeat-interval>
  heartbeat-threshold <heartbeat-threshold>
  no
  over-subscription
  pre-shared-key <pre-shared-key>
  preemption
  state-sync
```

Description

This command configures the High Availability:Fast Failover feature by assigning a managed device or standby controller to a high-availability group, and defining the deployment role for each controller.

The High Availability:Fast Failover feature supports redundancy models with an active controller pair, or an active or standby deployment model with one backup controller supporting one or more active controllers. Each of these clusters of active and backup controllers comprises a high-availability group. Note that all active and backup controllers within a single high-availability group must be deployed in a single conductor-local topology. The High Availability:Fast Failover feature works across Layer-3 networks, so there is no need for a direct Layer-2 connection between controllers in a high-availability group.

By default, the active controller of an AP is the controller to which the AP first connects when it comes up. Other dual mode or standby mode controllers in the same High Availability group become potential standby controllers for that AP. This feature does not require that the active controller act as the configuration conductor for the local standby controller. A conductor controller in a conductor-local deployment can act as an active or a standby controller.

When the AP first connects to its active controller, that controller sends the AP the IP address of a standby controller, and the AP attempts to connect to the standby controller. If an AP that is part of a cluster with multiple backup controllers fails to connect to the first standby controller, the active controller will select a new standby controller for that AP, and the AP will attempt to connect to that standby controller. APs using control plane security establish an IPsec tunnel to their standby controller. APs that are not configured to use control plane security send clear, unencrypted information to the standby controller.

An AP will failover to its backup controller if it fails to contact its active controller through regular heartbeats and keepalive messages, or if the user manually triggers a failover using the WebUI or CLI.

A controller using this feature can have one of three high-availability roles: **active**, **standby**, or **dual**. An active controller serves APs, but cannot act as a failover standby controller for any AP

except the ones that it serves as active. A standby controller acts as a failover backup controller, but cannot be configured as the primary controller for any AP. A dual controller can support both roles, and acts as the active controller for one set of APs, and also acts as a standby controller for another set of APs.

Parameter	Description
group-membership <group-membership>	Displays the high availability group in which the managed device or standby controller is a member.
ha group-profile <profile-name>	Creates a new high availability group, or define settings for an existing group.
clone <source>	Name of an existing high availability profile from which parameter values are copied.
controller <ip>	IPv4 address of a controller that should be added to the specified high availability group.
role	Assign one of the following roles to each controller in the high availability group. <ul style="list-style-type: none"> ▪ Active: controller is active and is serving APs. ▪ Dual: controller serves some APs and acts as a standby controller for other APs. ▪ Standby: controller does not serve APs, as only acts as a standby in case of failover.
controller-v6 <ipv6>	IPv6 address of a controller that should be added to the specified high availability group.
role	Assign one of the following roles to each controller in the high availability group. <ul style="list-style-type: none"> ▪ Active: controller is active and is serving APs. ▪ Dual: controller serves some APs and acts as a standby controller for other APs. ▪ Standby: controller does not serve APs, as only acts as a standby in case of failover.
ha-on-bkup-lms	This feature allows AP to honor the high availability configuration from bkup-lms and setup standby tunnel with standby controller, when AP reboots to bkup-lms.
heartbeat	The high availability inter-controller heartbeat feature allows for faster AP failover from an active controller to a standby controller, especially in situations where the active controller reboots or loses connectivity to the network.
heartbeat-interval <heartbeat-interval>	Enter a heartbeat interval in the Heartbeat Interval field to define how often inter-controller heartbeats are sent. 100-1000 ms

Parameter	Description
	100 ms
heartbeat-threshold <heartbeat-threshold>	Enter a heartbeat threshold in the Heartbeat Threshold field to define the number of heartbeats that must be missed before the APs are forced to fail over to the standby controller. 3-10 heartbeats 5 heartbeats
no	Negates or removes any configured parameter.
over-subscription	The standby controller over-subscription feature allows a standby controller to support connections to standby APs beyond the controller's original rated AP capacity. A controller acting as a standby controller can oversubscribe to standby APs by up to four times that controller's rated AP capacity, as long as the tunnels consumed the standby APs do not exceed the maximum tunnel capacity for that standby controller.
pre-shared-key <pre-shared-key>	Define a PSK to be used with the state synchronization feature. 8-32 characters
preemption	If you include this optional parameter to enable preemption, an AP that has failed over to a standby controller attempts to connect back to its original active controller once that controller is reachable again. When you enable this setting, the AP will wait for the time specified by the <code>lms-hold-down-period</code> parameter in the ap system-profile profile before the standby AP attempts to switch back to original controller.
state-sync	State synchronization improves failover performance by synchronizing PMK and Key cache values from the active controller to the standby controller, allowing clients to authenticate on the standby controller without repeating the complete 802.1X authentication process. NOTE: To use the state synchronization feature, configure a PSK with the pre-shared-key parameter.

Examples

The following commands configure a high availability group:

```
(host) [mynode] (config) #ha group-profile new
```

```
(host) [mynode] (HA group information "new") #controller 192.0.2.2 role active
(host) [mynode] (HA group information "new") #controller 192.0.2.3 role active
(host) [mynode] (HA group information "new") #controller 192.0.2.4 role standby
(host) [mynode] (HA group information "new") #preemption
```

Related Commands

halt

halt

Description

This command gracefully stops all processes on the Mobility Conductor. You should issue this command before rebooting or shutting down to avoid interrupting processes.

Starting from ArubaOS 8.11.0.0, the **halt** command can be issued only from the **/mm** and **/mm/mynode** nodes of the Mobility Conductor.

Command History

Release	Modification
ArubaOS 8.11.0.0	The command can be issued only from the /mm and /mm/mynode nodes of the Mobility Conductor.

help

help

Description

This command displays keyboard editing commands that allow you to make corrections or changes to the command without retyping.

You can also enter the question mark (?) to get various types of command help:

- When typed at the beginning of a line, the question mark lists all commands available in the current mode.
- When typed at the end of a command or abbreviation, the question mark lists possible commands that match.
- When typed in place of a parameter, the question mark lists available options.

Example

The following command displays help:

```
(host) [mynode] #help
HELP:
Special keys:
DEL, BS .... delete previous character
Ctrl-A .... go to beginning of line
Ctrl-E .... go to end of line
Ctrl-F .... go forward one character
Ctrl-B .... go backward one character
Ctrl-D .... delete current character
Ctrl-U, X .. delete to beginning of line
Ctrl-K .... delete to end of line
Ctrl-W .... delete previous word
Ctrl-T .... transpose previous character
Ctrl-P .... go to previous line in history buffer
Ctrl-N .... go to next line in history buffer
Ctrl-Z .... return to root command prompt
Tab, <SPACE> command-line completion
Exit .... go to next lower command prompt
?, Tab .... list choices
Help may be requested at any point in a command by entering
a question mark '?'. If nothing matches, the help list will
be empty and you must backup until entering a '?' shows the
available options.
Two styles of help are provided:
1. Full help is available when you are ready to enter a
command argument (e.g. 'show ?') and describes each possible
argument.
2. Partial help is provided when an abbreviated argument is entered
and you want to know what arguments match the input
```

```
(e.g. 'show w?'.)
If on entering a 'tab', command-line completion is not possible
at that point, the behavior will be similar to entering a '?'.
```

hidehash

```
hidehash {disable | enable}
```

Description

This command controls the display of hashed passwords for management user in CLI.

Parameter	Description
disable	Hash code for management user password is displayed as it is.
enable	Hash code for management user password is displayed in encrypted format.

Example

```
(host) [mm] #hidehash disable
```

hostname

hostname <hostname>

Description

This command changes the hostname of the Mobility Conductor, standby controller, or managed device. The hostname is used as the default prompt. You can use any alphanumeric character, punctuation, or symbol character. To use spaces, plus symbols (+), question marks (?), or asterisks (*), enclose the text in quotes.

Parameter	Description
<hostname>	The hostname of the Mobility Conductor, standby controller, or managed device. 1-63 characters

Example

The following example configures the Mobility Conductor hostname to "controller 1".

```
(host) [mm] (config) #hostname "controller 1"
```

Related Commands

http-ping

http-ping <url>

Description

This command measures the latency of a webserver.

Parameter	Description
<url>	Specify the url to webserver.

Example

```
(host) [mm] #http-ping www.google.com

Pinging 'www.google.com'

Press 'q' to abort.
1> Reply: [0/] bytes=0 time=5ms Rate=0.00KB/sec
2> Reply: [0/] bytes=0 time=5ms Rate=0.00KB/sec
3> Reply: [0/] bytes=0 time=0ms Rate=0.00KB/sec
4> Reply: [0/] bytes=0 time=0ms Rate=0.00KB/sec
5> Reply: [0/] bytes=0 time=0ms Rate=0.00KB/sec

Ping Statistics for www.google.com
Packets: Sent : 5 Received : 0 Success Rate is 0 percent (0/5)
Approximate round trip time : max/avg/min = 5/2/0 ms
```

iap del branch-key / iap del branch-name

iap del branch-key /iap del branch-name <brkey>

Description

This command removes a branch from the managed device based on the branch key.

Parameter	Description
branch-key <brkey>	Key for the branch, which is unique to each branch.

Example

```
(host) [mynode] #iap del branch-key  
b3c65c4d013836cf190566ca1afdf87c95350cffb1c782e463  
(host) [mynode] #iap del branch-name  
b3c65c4d013836cf190566ca1afdf87c95350cffb1c782e463
```

Related Command

iap trusted-branch-db

```
iap trusted-branch-db
  add {mac-address <mac-address>}
  allow-all
  del {mac-address <mac-address>}
  del-all
```

Description

This command is used to configure an Instant AP (IAP)-VPN branch as trusted.

Parameter	Description
add	Configure an IAP trusted branch entry.
mac-address <mac-address>	MAC-address of the IAP.
allow-all	Configure all branches as trusted.
del	Delete an IAP trusted branch entry.
mac-address <mac-address>	MAC-address of the IAP.
del-all	Delete all trusted branch entries.

Example

The following command configures a specific IAP-VPN branch as trusted:

```
(host) [mynode] #iap trusted-branch-db add mac-address 01:01:0e:3e:4c:33
```

The following is the output of the above command:

```
Trusted branch added
```

This following command configures all IAP-VPN branches as trusted:

```
(host) [mynode] #iap trusted-branch-db allow-all
All IAP+VPN branches are trusted
```

Related Command

Command	Description
show iap detailed-table	This command displays the IAP trusted branch table.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system, except for noted parameters.	Config or Enable mode on Mobility Conductor.

iapvpn-backward-compatible

iapvpn-backward-compatible
no...

Description

This command is used to enable the older Instant APs to send register requests on the older HTTP port of 80.

In some scenarios, the controllers and Instant APs may not be upgraded simultaneously. However, if the Managed devices are upgraded first and if this command is not executed, all the register requests that are received on HTTP port 80 will be dropped by the managed device, resulting in service disruption. To prevent this from happening, the administrator has to enable this command as soon as the managed devices are upgraded to this version.

Parameter	Description
no	Disables IAP-VPN backward compatibility.

Example

The following command enables backward compatibility on older Instant APs:

```
(host) [mynode] (config) #iapvpn-backward-compatible
```

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

ids ap-classification-rule

```
ids ap-classification-rule <rule-name>
  check-min-discovered-aps
  classify-to-type [neighbor|suspected-rogue]
  clone <source>
  conf-level-incr <conf-level-incr>
  discovered-ap-cnt <discovered-ap-cnt>
  match-ssids
  no
  snr-max <snr-max>
  snr-min <snr-min>
  ssid <ssid>
```

Description

This command configures the IDS AP classification rule profile.

AP classification rule configuration is performed only on the Mobility Conductor. If AMP is enabled via the mobility-manager command, then processing of the AP classification rules is disabled on Mobility Conductor. A rule is identified by its ASCII character string name (32 characters maximum). The AP classification rules must have one of the following specifications:

- SSID of the AP - Each rule can have up to six SSID parameters. If one or more SSIDs are specified in a rule, an option of whether to match any of the SSIDs, or to not match all of the SSIDs can be specified. The default is to check for a match operation.
- SNR of the AP- Each rule can have only one specification of the SNR. A minimum and maximum can be specified in each rule, and the specification is in SNR (db).
- Discovered-AP-Count or the number of APs that can see the AP- Each rule can have only one specification of the discovered-AP-count. Each rule can specify a minimum or maximum of the discovered-AP-count. The minimum or maximum operation must be specified if the discovered-AP-count is specified. The default setting is to check for the minimum discovered-AP-count.

Parameter	Description
<rule-name>	Name of the AP classification rule profile.
check-min-discovered-aps	Enables a rule check for the minimum number of APs. true
classify-to-type	Specifies the AP classification type as neighbor or suspected-rogue if the rule is matched. suspected-rogue
clone <source>	Copies data from another AP classification rule profile.

Parameter	Description
<code>conf-level-incr</code>	Increases the confidence level (in percentage) when the rule matches. 0-100 5
<code>discovered-ap-cnt</code> <code><discovered-ap-cnt></code>	The number of APs to be discovered. 0-100 0
<code>match-ssids</code>	Matches SSIDs. true false false
<code>no</code>	Negates any configured parameter.
<code>snr-max <snr-max></code>	Configures the maximum SNR value. 0-100 0
<code>snr-min <snr-min></code>	Configures the minimum SNR value. 0-100 0
<code>ssid <ssid></code>	Enter the keyword ssid followed by the SSID string to be matched or excluded

After you have created an AP classification rule, you must enable the rule by adding it to the IDS AP Matching Rules profile:

```
ids ap-rule-matching
rule-name <name>
```

Example

The following example configures the AP Configuration Rule Profile named "rule1", and then enables the rule by adding it to the IDS AP Matching Rules profile:

```
(host) [mynode] (config) #ids ap-classification-rule rule1
(host) [mynode] (IDS AP Classification Rule Profile "rule1") #check-min-
discovered-aps
(host) [mynode] (IDS AP Classification Rule Profile "rule1") #classify-to-
type neighbor
```

ids ap-rule-matching

```
ids ap-rule-matching
  no
  rule-name <rule-name>
```

Description

This command configures the IDS active AP rules profile by enabling an AP classification rule. This command also activates an active AP rule created by the `ids ap-classification-rule` command. You must create the rule before you can activate it.

Parameter	Description
no	Negates any configured parameter.
rule-name <rule-name>	Name of the IDS AP classification rule to activate.

Example

```
(host) [mynode] (IDS Active AP Rules Profile) #rule-name rule2
```

Description

This command configures traffic anomalies for DoS attacks. DoS attacks are designed to prevent or inhibit legitimate clients from accessing the network. This includes blocking network access completely, degrading network service, and increasing processing load on clients and network equipment.

Parameter	Description
<profile-name>	Name of the IDS DoS profile. 1-63 characters "default"
ap-flood-inc-time <ap-flood-inc-time>	Time, in seconds, during which the AP count is over the threshold (AP flood). 0-36000 seconds 3600 seconds
ap-flood-quiet-time <ap-flood-quiet-time>	After an alarm has been triggered by an AP flood, the time, in seconds, that must elapse before an identical alarm may be triggered. 60-360000 seconds

Parameter	Description
	900 seconds
ap-flood-threshold <ap-flood-threshold>	Threshold for the number of spurious APs in the system. 0-100,000 50
assoc-rate-thresholds <assoc-rate-thresholds>	Rate threshold for associate request frames.
auth-rate-thresholds <auth-rate-thresholds>	Rate threshold for authenticate frames.
block-ack-dos-quiet-time <block-ack-dos-quiet-time>	Time to wait, in seconds, after detecting an attempt to reset the receive window using a forged block ACK add. 60-360000 seconds 900 seconds
chopchop-quiet-time <chopchop-quiet-time>	Time to wait, in seconds, after detecting a ChopChop attack after which the check can be resumed. 60-360000 seconds 900 seconds
client-ht-40mhz-intol-quiet-time <client-ht-40mhz-intol-quiet=time>	Quiet time (when to stop reporting intolerant STAs if they have not been detected), in seconds, for detection of 802.11n 40 MHz intolerance setting. 60-360000 seconds 900 seconds
client-flood-inc-time <client-flood-inc-time>	Number of consecutive seconds over which the client count is more than the threshold. 0-36000 seconds 3 seconds
client-flood-quiet-time <client-flood-quiet-time>	Time to wait, in seconds, after detecting a client flood before continuing the check. 60-360000 seconds 900 seconds
client-flood-threshold <client-flood-threshold>	Threshold for the number of spurious clients in the system. 0-100000

Parameter	Description
	150
clone <source>	Copies data from another IDS Denial Of Service Profile.
cts-rate-quiet-time <cts-rate-quiet-time>	Time to wait, in seconds, after detecting a CTS rate anomaly after which the check can be resumed. 60-360000 seconds 900 seconds
cts-rate-threshold <cts-rate-threshold>	Number of CTS control packets over the time interval that constitutes an anomaly. 0-100000 5000
cts-rate-time-interval <cts-rate-time-interval>	Time interval, in seconds, over which the packet count should be checked. 1-120 seconds 5 seconds
deauth-rate-thresholds <deauth-rate-thresholds>	Rate threshold for deauthenticate frames.
detect-ap-flood	Enables or disables detection of AP flood attacks. disabled
detect-block-ack-dos	Enables or disables detection of attempts to reset traffic receive windows using forged Block ACK Add messages. enabled
detect-chopchop-attack	Enables or disables detection of ChopChop attacks. disabled
detect-client-flood	Enables or disables detection of client flood attacks. disabled
detect-cts-rate-anomaly	Enables or disables detection of CTS rate anomalies. disabled

Parameter	Description
detect-disconnect-sta	<p>In a station disconnection attack, an attacker spoofs the MAC address of either an active client or an active AP. The attacker then sends deauthenticate frames to the target device, causing it to lose its active association.</p> <p>Use this command to enable the detection of disconnect station attack.</p> <p>enabled</p>
detect-eap-rate-anomaly	<p>Enables or disables detection of the EAP handshake rate anomaly.</p> <p>disabled</p>
detect-fata-jack-attack	<p>Enables or disables detection of FATA-Jack attacks.</p> <p>enabled</p>
detect-ghosttunnel-client-attack	<p>Enables or disables detection of ghost tunnel client attacks.</p> <p>disabled</p>
detect-ghosttunnel-server-attack	<p>Enables or disables detection of ghost tunnel server attacks.</p> <p>disabled</p>
detect-ht-40mhz-intolerance	<p>Enables or disables detection of 802.11n 40 MHz intolerance setting, which controls whether stations and APs advertising 40 MHz intolerance will be reported.</p> <p>disabled</p>
detect-invalid-address	<p>Enables or disables detection of invalid address combinations.</p> <p>disabled</p>
detect-malformed-association-request	<p>Enables or disables detection of malformed association requests.</p> <p>disabled</p>
detect-malformed-auth-frame	<p>Enables or disables detection of malformed authentication frames.</p> <p>disabled</p>
detect-malformed-htie	<p>Enables or disables detection of malformed HT IE.</p> <p>disabled</p>

Parameter	Description
detect-malformed-large-duration	Enables or disables detection of unusually large durations in frames. enabled
detect-omerta-attack	Enables or disables detection of Omerta attacks. enabled
detect-overflow-eapol-key	Enables or disables detection of overflow EAPOL key requests. disabled
detect-overflow-ie	Enables or disables detection of overflow IEs. disabled
detect-power-save-dos-attack	Enables or disables detection of Power Save DoS attacks. enabled
detect-rate-anomalies	Enables or disables detection of rate anomalies. disabled
detect-rts-rate-anomaly	Enables or disables detection of RTS rate anomalies. disabled
detect-tkip-replay-attack	Enables or disables detection of TKIP replay attacks. disabled
detect-wpa-ft-attack	Enables or disables detection of WPA FT attacks. disabled
disassoc-rate-thresholds <disassoc-rate-thresholds>	Rate threshold for disassociate frames.
disconnect-deauth-disassoc-threshold <disconnect-deauth-disassoc-threshold>	Number of deauthentication or disassociation frames seen in an interval of 10 seconds. 1-50 8
disconnect-sta-assoc-resp-threshold <disconnect-sta-assoc-resp-threshold>	The number of successful Association Response or Reassociation response frames seen in an interval of 10 seconds.

Parameter	Description
	1-30 5
disconnect-sta-quiet-time <disconnect-sta-quiet-time>	After a station disconnection attack is detected, the time, in seconds, that must elapse before the check can be resumed. 60-360000 seconds 900 seconds
eap-rate-quiet-time <eap-rate-quiet-time>	After an EAP rate anomaly alarm has been triggered, the time, in seconds, that must elapse before the check can be resumed. 60-360000 seconds 900 seconds
eap-rate-threshold <eap-rate-threshold>	Number of EAP handshakes that must be received within the EAP rate time interval to trigger an alarm. 0-100000 60
eap-rate-time-interval <eap-rate-time-interval>	Time, in seconds, during which the configured number of EAP handshakes must be received to trigger an alarm. 1-120 seconds 3 seconds
fata-jack-quiet-time <fata-jack-quiet-time>	Time to wait, in seconds, after detecting a FATA-Jack attack after which the check can be resumed. 60-360000 seconds 900 seconds
ghosttunnel-client-attack-interval <ghosttunnel-client-attack-interval>	Time interval, in seconds, over which the packet count is checked. Default is 60 seconds. Maximum is 600 seconds.
ghosttunnel-client-attack-threshold <ghosttunnel-client-attack-threshold>	Number of probe request management packets for a fake AP over the time interval that constitutes a ghost tunnel attack. Default is 10. Maximum is 100000.
ghosttunnel-client-quiet-time <ghosttunnel-client-quiet-time>	Time to wait, in seconds, after detecting a ghost tunnel attack after which the check is resumed. Default is 900 seconds. Minimum is 60 seconds.

Parameter	Description
ghosttunnel-server-attack-interval <ghosttunnel-server-attack-interval>	Time interval, in seconds, over which the packet count is checked. Default is 60 seconds. Maximum is 600 seconds.
ghosttunnel-server-attack-threshold <ghosttunnel-server-attack-threshold>	Number of beacon management packets for a fake AP over the time interval that constitutes a ghost tunnel attack. Default is 200. Maximum is 10000.
ghosttunnel-server-quiet-time <ghosttunnel-server-quiet-time>	Time to wait, in seconds, after detecting a ghost tunnel attack after which the check is resumed. Default is 900 seconds. Minimum is 60 seconds.
invalid-address-combination-quiet-time <invalid-address-combination-quiet-time>	Time to wait, in seconds, after detecting an invalid address combination after which the check can be resumed. 60-360000 seconds 900 seconds
malformed-association-request-quiet-time <malformed-association-request-quiet-time>	Time to wait, in seconds, after detecting a malformed association request after which the check can be resumed. 60-360000 seconds 900 seconds
malformed-auth-frame-quiet-time <malformed-auth-frame-quiet-time>	Time to wait, in seconds, after detecting a malformed authentication frame after which the check can be resumed. 60-360000 seconds 900 seconds
malformed-htie-quiet-time <malformed-htie-quiet-time>	Time to wait, in seconds, after detecting a malformed HT IE after which the check can be resumed. 60-360000 seconds 900 seconds
malformed-large-duration-quiet-time <malformed-large-duration-quiet-time>	Time to wait, in seconds, after detecting a large duration for a frame after which the check can be resumed. 60-360000 seconds 900 seconds
no	Negates any configured parameter.

Parameter	Description
omerta-quiet-time <omerta-quiet-time>	Time to wait, in seconds, after detecting an Omerta attack after which the check can be resumed. 60-360000 seconds 900 seconds
omerta-threshold <omerta-threshold>	The Disassociation packets received by a station as a percentage of the number of data packets sent, in an interval of 10 seconds. 1-100 10%
overflow-eapol-key-quiet-time <overflow-eapol-key-quiet-time>	Time to wait, in seconds, after detecting a overflow EAPOL key request after which the check can be resumed. 60-360000 seconds 900 seconds
overflow-ie-quiet-time <overflow-ie-quiet-time>	Time to wait, in seconds, after detecting a overflow IE after which the check can be resumed. 60-360000 seconds 900 seconds
power-save-dos-min-frames <power-save-dos-min-frames>	The minimum number of Power Management OFF packets that are required to be seen from a station, in intervals of 10 second, in order for the Power Save DoS check to be done. 1-1000 120
power-save-dos-quiet-time <power-save-dos-quiet-time>	Time to wait, in seconds, after detecting a Power Save DoS attack after which the check can be resumed. 60-360000 seconds 900 seconds
power-save-dos-threshold <power-save-dos-threshold>	The Power Management ON packets sent by a station as a percentage of the Power Management OFF packets sent, in intervals of 10 second, which will trigger this event. 1- 100% 80%

Parameter	Description
probe-request-rate-thresholds <probe-request-rate-thresholds>	Rate threshold for probe request frames.
probe-response-rate-thresholds <probe-response-rate-thresholds>	Rate threshold for probe response frames.
rts-rate-quiet-time <rts-rate-quiet-time>	Time to wait, in seconds, after detecting an RTS rate anomaly after which the check can be resumed. 60-360000 seconds 900 seconds
rts-rate-threshold <rts-rate-threshold>	Number of RTS control packets over the time interval that constitutes an anomaly. 0-100000 5000
rts-rate-time-interval <rts-rate-time-interval>	Time interval, in seconds, over which the packet count should be checked. 1-120 seconds 5 seconds
tkip-replay-quiet-time <tkip-replay-quiet-time>	Time to wait, in seconds, after detecting a TKIP replay attack after which the check can be resumed. 60-360000 seconds 900 seconds
wpa-ft-quiet-time <wpa-ft-quiet-time>	Time to wait, in seconds, after detecting a WPA FT attack after which the check can be resumed. 60-360000 seconds 900 seconds
wpa-ft-threshold <wpa-ft-threshold>	Number of reassociation management packets for a particular client over the time interval that constitutes a WPA FT attack. 0-100000 45
wpa-ft-time-interval <wpa-ft-time-interval>	Time interval, in seconds, over which the packet count should be checked. 1-120 seconds 60 seconds

Example

The following command enables a detection in the DoS profile named "floor2":

```
(host) [mynode] (config) #ids dos-profile floor2
(host) [mynode] (IDS Denial Of Service Profile "floor2") detect-ap-flood
```

Related Command

Description

This command configures an IDS general profile and IDS profile attributes.

The feature for enabling wireless containment under the **IDS Unauthorized Device** profile and **IDS Impersonation** profile may be in violation of certain FCC regulatory statutes. To address this, a warning message will be issued each time the command is enabled through the CLI. The warning message will appear after the command is executed.

Parameter	Description
<profile-name>	Name that identifies an instance of the profile. The name must be 1-63 characters. default
adhoc-ap-inactivity-timeout	Ad hoc (IBSS) AP inactivity timeout, in number of scans. 5-36000 seconds 5 seconds
adhoc-ap-max-unseen-timeout	Ageout time, in seconds, since ad hoc (IBSS) AP was last seen. 5-36000 seconds 5 seconds
ap-inactivity-timeout	Time, in seconds, after which an AP is aged out. 5-36000 seconds 5 seconds
ap-max-unseen-timeout	Ageout time, in seconds, since AP was last seen. 5-36000 seconds 600 seconds
ap-nbr-msg	Enables or disables AP neighbor messages. disabled
ap-nbr-msg-interval	Interval, in seconds, at which an AP delivers AP neighbor messages to the management server. 1-36000 seconds 1 second
client-detection-mode	NOTE: This setting applies only to detection of clients on scan channels in AP mode. Specify one of the following client detection mode: <ul style="list-style-type: none"> ▪ Normal: AP needs to detect only unidirectional traffic to discover the client. ▪ Strict: AP needs to detect bidirectional traffic to discover the client. This mode protects from invalid client entries being detected, but may increase the time taken to detect clients on scan channels.
clone	Name of an existing IDS general profile from which parameter values are copied.
frame-types-for-rssi	Select frame types to be used in AM RSSI calculation.

Parameter	Description
all ba ctrl dhigh dlow dnull mgmt pr	Frame types: <ul style="list-style-type: none"> ▪ all—All types of frames. This frame type overrides any other frame types. ▪ ba—Block ACK frame types. ▪ ctrl—All control frames except ACK. ▪ dhigh—Data frames more than 36 Mbps except null data frames. ▪ dlow—Data frames less than 36 Mbps except null data frames. ▪ dnull—Null data frames. ▪ mgmt—All management frames except probe request. ▪ pr—Probe request frames. <p>NOTE: Configure this parameter under the supervision of Aruba Technical Support.</p> <p>ba, ctrl, dlow, dnull, mgmt, pr</p>
ids-events logs-and-traps logs-only none traps-only]	Enables or disables IDS event generation from the AP. Event generation from the AP can be enabled for syslogs, traps, or both. This does not affect generation of IDS correlated events on the switch. <p>logs-and-traps</p>
max-monitored-aps	Maximum number of BSSIDs that can be monitored by a single AP. The actual upper limit may be smaller than the configured limit based on the available memory on different AP platforms. When set to 0, the default maximum value allowed for the AP platform will be applied. Display the maximum value with CLI command <code>show ap monitor debug profile-config ids-general</code> . <p>0</p>
max-monitored-devices	Maximum number of APs and stations that can be monitored. This number does not include stations that are not associated to any AP. Within this max value, the AP reserves a buffer for stations that are associated locally. Configure this parameter under the supervision of Aruba Technical Support. <p>1024-4096</p> <p>1024 or 4096, depending on the AP platform.</p>
max-unassociated-stations	Maximum number of unassociated stations. <p>NOTE: Configure this parameter under the supervision of Aruba Technical Support.</p> <p>256-4096</p>

Parameter	Description
	512
min-pot-ap-beacon-rate	Minimum beacon rate acceptable from a potential AP, in percentage of the advertised beacon interval. 0-100% 25%
min-pot-ap-monitor-time	Minimum time, in seconds, a potential AP has to be up before it is classified as a real AP. 2-36000 seconds 2 seconds
mobility-manager-rtls	Enables or disables RTLS communication with the configured mobility-manager. disabled
mon-stats-update-interval	Time interval, in seconds, for the AP to update the switch with stats for monitored devices. 60-36000 seconds 60 seconds
no	Negates any configured parameter.
packet-snr-threshold	Sets the packet SNR threshold. All packets with SNR below this threshold is dropped from IDS and ARM processing. No packets are dropped if the threshold is set to 0. NOTE: Configure this parameter under the supervision of Aruba Technical Support. 0-90 dB 0
radio-info-ext-msg-interval	Specify interval in seconds for AP to deliver Radio Info Ext messages to the management servers. Minimum is 1 seconds. 300 seconds
send-adhoc-info-to-controller	Enables or disables sending ad hoc information to the controller from the AP. disabled
signature-quiet-time	After a signature match is detected, the time to wait, in seconds, to resume checking. 60-36000 seconds 900 seconds

Parameter	Description
<code>sta-inactivity-timeout</code>	Time, in seconds, after which a station is aged out. 30-36000 seconds 60 seconds
<code>sta-max-unseen-timeout</code>	Ageout time, in seconds, since station was last seen. 5-36000 seconds 600 seconds
<code>sta-rssi-msg</code>	Enables or disables station RSSI messages. disabled
<code>sta-rssi-msg-interval</code>	Interval, in seconds, at which the AP delivers station RSSI messages to the management server. 1-36000 1 second
<code>stats-update-interval</code>	Interval, in seconds, for the AP to update the controller with statistics. 60-36000 seconds 60 seconds
<code>unclass-ap-update</code>	Enables or disables classification updates for monitored APs. If this option is enabled, there is a decrease in the delay with which the devices are classified. disabled
<code>unclass-device-update-interval</code>	The time interval, in seconds, for the AP to send the WMS a list of unclassified APs and clients. 30-36000 seconds 60 seconds
<code>unclass-sta-update</code>	Enables or disables classification updates for monitored clients. If this option is enabled, there is a decrease in the delay with which the devices are classified. disabled
<code>wired-containment</code>	Enables or disables containment from the wired side. disabled
<code>wired-containment-ap-adj-mac</code>	Enables or disables wired containment of MACs offset by one from APs BSSID. disabled

Parameter	Description
wired- containment-susp-l3-rogue	<p>The basic wired containment feature enabled using the command contains layer-3 APs whose wired interface MAC addresses are either the same as (or one character off from) their BSSIDs. This feature can also identify and contain an AP with a preset wired MAC address that is completely different from the AP's BSSID if the MAC address that the AP provides to wireless clients as the 'gateway MAC' is offset by one character from its wired MAC address.</p> <p>NOTE: This feature requires that the following parameter in the ids general-profile is also enabled, and that the confidence level of the suspected rogue exceeds the level configured by the and parameters in the ids unauthorized-device-profile.</p>
wireless-containment	<p>Selects one of the following containment types from the wireless side:</p> <ul style="list-style-type: none"> ▪ death-only: Containment using deauthentication only. ▪ none: Disables wireless containment. ▪ tarpit-all-sta: Wireless containment by tarpit of all stations. ▪ tarpit-non-valid-sta: Wireless containment by tarpit of non-valid clients.
wireless-containment-death-reason	<p>Specify the death reason for containment from the wireless side. Range: 1 - 134. Default: 3</p>
wireless-containment-debug	<p>Enables or disables debugging of containment from the wireless side. Enabling this debug option will cause containment to not function properly.</p>
wms-client-monitoring	<p>Specify the WMS client monitoring level. This level controls which clients are monitored by WMS in the controller. The recommended value is 'all' to ensure full functionality of the system. Lowering the value will have a significant effect on features that rely on client classification or neighboring client signal strength. This setting should only be changed after consulting with TAC. all</p>

Example

The following commands enable containment in the general IDS profile:

```
(host) [mynode] (config) #ids general-profile floor7
(host) [mynode] (IDS General Profile "floor7") #wired-containment
(host) [mynode] (IDS General Profile "floor7") #wireless-containment tarpit-
all-sta
(host) [mynode] (IDS General Profile "floor7") #wireless-containment-debug
```

Command History

Release	Description
ArubaOS 8.9.0.0	The <code>wireless-containment-death-reason</code> parameter was introduced.
ArubaOS 8.5.0.0	The default value of <code>max-monitored-devices</code> parameter was modified to include both 1024 and 4096.
ArubaOS 8.0.0.0	Command introduced.

ids impersonation-profile

```
ids impersonation-profile <profile-name>
  ap-spoofing-quiet-time <ap-spoofing-quiet-time>
  beacon-diff-threshold <beacon-diff-threshold>
  beacon-inc-wait-time <beacon-inc-wait-time >
  beacon-wrong-channel-quiet-time <beacon-wrong-channel-quiet-time>
  chan-based-mitm-quiet-time <chan-based-mitm-quiet-time>
  clone <source>
  detect-ap-impersonation
  detect-ap-spoofing
  detect-beacon-wrong-channel
  detect-chan-based-mitm
  detect-hotspotter
  hotspotter-quiet-time <hotspotter-quiet-time>
  no
  protect-ap-impersonation
```

Description

This command configures anomalies for impersonation attacks.

Parameter	Description
<profile-name>	Name that identifies an instance of the profile. 1-63 characters "default"
ap-spoofing-quiet-time <ap-spoofing-quiet-time>	Time to wait, in seconds, after detecting AP Spoofing after which the check can be resumed. 60-360000 seconds 60 seconds
beacon-diff-threshold <beacon-diff-threshold>	Percentage increase, in beacon rates, that triggers an AP impersonation event. 0-100% 50%
beacon-inc-wait-time <beacon-inc-wait-time >	Time, in seconds, after the beacon difference threshold is crossed before an AP impersonation event is generated. 3 seconds
beacon-wrong-channel-quiet-time <beacon-wrong-channel-quiet-time>	Time to wait, in seconds, after detecting a beacon with the wrong channel after which the check can be resumed. 60-360000 seconds

Parameter	Description
	900 seconds
chan-based-mitm-quiet-time <chan-based-mitm-quiet-time>	Time to wait, in seconds, after detecting man-in-the-middle attack after which the check can be resumed. 60-360000 seconds 900 seconds
clone <source>	Name of an existing IDS impersonation profile from which parameter values are copied.
detect-ap-impersonation	Enables or disables detection of AP impersonation. In AP impersonation attacks, the attacker sets up an AP that assumes the BSSID and ESSID of a valid AP or a neighboring AP. AP impersonation attacks can be done for man-in-the-middle attacks, a rogue AP attempting to bypass detection, or a honeypot attack. enabled
detect-ap-spoofing	Enables or disables AP Spoofing detection. enabled
detect-beacon-wrong-channel	Enables or disables detection of beacons advertising the incorrect channel. disabled
detect-chan-based-mitm	Enables or disables channe-based man-in-the-middle attack detection. disabled
detect-hotspotter	Enables or disables detection of the Hotspotter attack to lure away valid clients. disabled
hotspotter-quiet-time <hotspotter-quiet-time>	Time to wait, in seconds, after detecting an attempt to use the Hotspotter tool against clients. 60-360000 seconds 900 seconds
no	Negates any configured parameter.
protect-ap-impersonation	When AP impersonation is detected, both the legitimate and impersonating AP are disabled using a denial of service attack. disabled

Example

The following command enables detections in the impersonation profile:

```
(host) [mynode] (config) #ids impersonation-profile floor1
(host) [mynode] (IDS Impersonation Profile "floor1") #detect-beacon-wrong-channel
(host) [mynode] (IDS Impersonation Profile "floor1") #detect-ap-impersonation
```

Related Command

ids management-profile

```
ids management-profile
  event-correlation [logs-and-traps|logs-only|none|traps-only]
  event-correlation-quiet-time <event-correlation-quiet-time>
```

Description

This command configures the IDS WMS management profile and manages the events correlation for IDS event traps and syslogs (logs).

Parameter	Description
event-correlation	<p>Correlation mode for IDS event traps and syslogs (logs). Event correlation can be enabled with generation of correlated logs, traps, or both. To disable correlation, enter the keyword none.</p> <ul style="list-style-type: none">▪ logs-and-traps: Enables IDS event correlation with generation of correlated syslogs and traps.▪ logs-only: Enables IDS event correlation with generation of correlated syslogs only.▪ none: Disables IDS event correlation.▪ traps-only: Enables IDS event correlation with generation of correlated traps only. <p>logs-and-traps</p>
event-correlation-quiet-time	<p>Time to wait, in seconds, after generating a correlated event after which the event could be raised again. This only applies to events that are repeatedly raised by an AP.</p> <p>30-360000 seconds 900 seconds</p>

Example

```
(host) [mynode] (config) #ids management-profile
(host) [mynode] (IDS Management Profile) #event-correlation-quiet-time 30
(host) [mynode] (IDS Management Profile) #event-correlation logs-and-traps

ids profile

```
ids profile <profile-name>
  clone <source>
  dos-profile <profile-name>
  general-profile <profile-name>
  impersonation-profile <profile-name>
  no
  signature-matching-profile <profile-name>
  unauthorized-device-profile <profile-name>
```

Description

This command defines a set of IDS profiles that you can then apply to an AP group (with the `ap-group` command) or to a specific AP (with the `ap-name` command).

Parameter	Description
<profile-name>	Name that identifies an instance of the profile. The name must be 1-63 characters. "default"
clone <source>	Name of an existing IDS profile from which parameter values are copied.
dos-profile <profile-name>	Name of a IDS DoS profile to be applied to the AP group or name. See ids dos-profile on page 682 . "default"
general-profile <profile-name>	Name of an IDS general profile to be applied to the AP group or name. See ids general-profile on page 694 . "default"
impersonation-profile <profile-name>	Name of an IDS impersonation profile to be applied to the AP group or name. See ids impersonation-profile on page 701 . "default"
no	Negates any configured parameter.
signature-matching-profile <profile-name>	Name of an IDS signature matching profile to be applied to the AP group or name. See ids signature-matching-profile on page 715 "default"
unauthorized-device-profile <profile-name>	Name of an IDS unauthorized device profile to be applied to the AP group or name. See ids unauthorized-device-profile on page 720 . "default"

Example

The following command defines a set of IDS profiles:

```
(host) [mynode] (config) #ids profile floor2
(host) [mynode] (IDS Profile "floor2") #dos-profile dos1
general-profile general1
impersonation-profile mitm1
signature-matching-profile sig1
unauthorized-device-profile unauth1
```

Related Commands

Command	Description
ids dos-profile	Configures an IDS DoS profile.

ids rap-wml-server-profile

```
ids rap-wml-server-profile <server-name>
  ageout <ageout>
  cache{disable|enable}
  clone <source>
  db-name <db-name>
  ip-addr <ip-addr>
  password <password>
  rap-wml-table <profile-name>
  type {mssql|mysql}
  user <user>
no ...
```

Description

This command to configure an IDS remote AP WML (MSSQL or MySQL) server profile.

Parameter	Description
<server-name>	Name of the remote AP WML server.
ageout <ageout>	Specifies the cache ageout period, in seconds. 0
cache	Enables or disables the cache.
clone <source>	Copies configuration settings from an existing profile.
db-name <db-name>	Specifies the name of the database.
ip-addr <ip-addr>	Specifies the IP address of the named WML server. 0.0.0.0
no	Negates any configured parameter.
password <password>	Specifies the password required for database login.
rap-wml-table <profile-name>	Specifies the name of the RAP WML Table profile.
type	Specifies the server type: <ul style="list-style-type: none">▪ MSSQL server▪ MySQL server
user <user>	Specifies the user name required for database login.

Example

This example configures an MSSQL server and sets up associated rap-wml table attributes for that server:

```
(host) [mynode] (config) # ids rap-wml-server-profile
mssqlserver type mssql ip-addr 10.4.11.11 db-name automatedtestdatabase
user sa password sa
ids rap-wml-table-profile mssqlserver table-name mactest_
undelimited timestamp-column time lookup-time 600
ids rap-wml-table-profile mssqlserver table-name mactest_delimited mac-
delimiter : timestamp-column time lookup-time 600
```

Related Commands

Command	Description
show rap-wml	Displays configuration information for the MSSQL or MySQL server.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

ids rap-wml-table-profile

```
ids rap-wml-table-profile <table-name>
  clone <source>
  column-name <column-name>
  lookup-time <lookup-time>
  mac-delimiter <mac-delimiter>
  no
  table-name <table-name>
  timestamp-column <timestamp-column-name>
```

Description

This command configures an IDS remote AP WML table profile.

Parameter	Description
<table-name>	Name of an IDS remote AP WML table profile.
clone <source>	Copies data from another IDS remote AP WML table profile.
column-name <column-name>	Specifies the database column name containing the MAC address.
lookup-time <lookup-time>	Specifies how far back, in seconds, to look for the MAC address. Use 0 seconds to look up everything.
mac-delimiter <mac-delimiter>	Specifies the optional delimiter character for the MAC address in the database.
no	Negates the rap-wml table for the named server.
table-name <table-name>	Specifies the database table name.
timestamp-column <timestamp-column-name>	Specifies the database column name with the timestamp last seen.

Example

This example configures a MySQL server and sets up associated rap-wml table attributes for that server:

```
(host) [mynode] (config) #ids rap-wml-server-profile mysqlserver type mysql
ip-addr 10.4.11.10 db-name automatedtestdatabase user sa password sa
```

```
ids rap-wml-table-profile mysqlserver table-name mactest_
undelimited timestamp-column time lookup-time 600
ids rap-wml-table-profile table-name mysqlserver mactest_delimited mac-
delimiter : timestamp-column time lookup-time 600
```

This example configures an MSSQL server and sets up associated rap-wml table attributes for that server:

```
(host) [mynode] (config) # ids rap-wml-server-profile
mysqlserver type mssql ip-addr 10.4.11.11 db-name automatedtestdatabase
user sa password sa
ids rap-wml-table-profile mssqlserver table-name mactest_
undelimited timestamp-column time lookup-time 600
ids rap-wml-table-profile mssqlserver table-name mactest_delimited mac-
delimiter : timestamp-column time lookup-time 600
```

Related Commands

Command	Description

  clone <profile>
  no ...
  node-quiet-time <node-quiet-time>
  node-threshold <node-threshold>
  node-time-interval <node-time-interval>
```

Description

This command configures an IDS rate thresholds profile.

A profile of this type is attached to each of the following 802.11 frame types in the IDS denial of service profile:

- association frames
- disassociation frames
- deauthentication frames
- probe Request frames
- probe Response frames
- authentication frames

Parameter	Description
<profile-name>	Name that identifies an instance of the profile. The name must be 1-63 characters.
channel-inc-time <channel-inc-time>	Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm. 0 - 360000 seconds 15 seconds
channel-quiet-time <channel-quiet-time>	After a channel rate anomaly alarm has been triggered, the time that must elapse before another identical alarm may be triggered. This option prevents excessive messages in the log file. 60-360000 seconds 900 seconds
channel-threshold	Number of specific frame types that must be exceeded within a specific interval in a channel to trigger an alarm. 0-100000 frames 300

Parameter	Description
<code>clone <source></code>	Copies an existing IDS rate thresholds profile.
<code>no</code>	Negates any configured parameter.
<code>node-quiet-time</code> <code><node-quiet-time></code>	After a node rate anomaly alarm has been triggered, the time, in seconds, that must elapse before another identical alarm may be triggered. This option prevents excessive messages in the log file. 60-360000 seconds 900 seconds
<code>node-threshold</code> <code><node-threshold></code>	Number of a specific type of frame that must be exceeded within a specific interval for a particular client MAC address to trigger an alarm. 0 -100000 frames 200
<code>node-time-interval</code> <code><node-time-interval></code>	Time, in seconds, in which the threshold must be exceeded in order to trigger an alarm. 1-120 seconds 15 seconds

Example

The following command configures frame thresholds:

```
(host) [mynode] (config) #ids rate-thresholds-profile Lobby
(host) [mynode] (IDS Rate Thresholds Profile "Lobby") #channel-threshold 250
```

Related Commands

Command	Description

ids signature-matching-profile

```
ids signature-matching-profile <profile-name>
  clone <source>
  no
  signature <profile-name>
```

Description

This command configures an IDS signature matching profile. You can include one or more predefined signature profiles or a user-defined signature profile in a signature matching profile.

Parameter	Description
<profile-name>	Name that identifies an instance of the profile. 1-63 characters
clone <source>	Name of an existing IDS signature matching profile from which parameter values are copied.
no	Negates any configured parameter.
signature <profile-name>	Name of a signature profile. See ids signature-profile on page 717 .

Example

The following command configures a signature matching profile:

```
(host) [mynode] (config) IDS signature matching LobbyEast
(host) [mynode] (IDS Signature Matching Profile "LobbyEast") #signature
Null-Probe-Response
```

ids signature-profile

```
ids signature-profile <profile-name>
  bssid <mac-addr> [valid-ap]
  clone <source>
  dst-mac <mac-addr> [valid-ap]
  frame-type {assoc|auth|beacon|control|data|deauth|disassoc|mgmt|probe-request
  {ssid <ssid>}{ssid-length <ssid-length>}|probe-response {ssid <ssid>}{ssid-length
  <ssid-length>}}
  no
  payload <pattern> [offset <offset>]
  seq-num <seq-num>
  src-mac <mac-addr> [valid-ap]
```

Description

This command configures signatures for wireless intrusion detection.

Parameter	Description
<profile-name>	Name that identifies an instance of the profile. The name must be 1-63 characters.
bssid <mac-addr>	BSSID field in the 802.11 frame header.
valid-ap	Matches a valid AP SSID.
clone <source>	Name of an existing IDS signature profile from which parameter values are copied.
dst-mac <mac-addr>	Destination MAC address in the 802.11 frame header.
valid-ap	Matches a valid AP SSID.
frame-type	Type of 802.11 frame. For each type of frame, further parameters can be specified to filter and detect only the required frames.
assoc	Association frame type
auth	Authentication frame type
beacon	Beacon frame type
control	All control frames
data	All data frames
deauth	Deauthentication frame type

Parameter	Description
disassoc	Disassociation frame type
mgmt	Management frame type
probe-request	Probe request frame type
probe-response	Probe response frame type
ssid <ssid>	For beacon, probe-request, and probe-response frame types, specify the SSID as either a string or hex pattern. 0-32 bytes
ssid-length <ssid-length>	For beacon, probe-request, and probe-response frame types, specify the length, in bytes, of the SSID. 0-32 bytes
no	Negates any configured parameter.
payload <pattern>	Pattern at a fixed offset in the payload of an 802.11 frame. Specify the pattern to be matched as a string or hex pattern. 0-32 bytes
offset <offset>	When a payload pattern is configured, specify the offset in the payload where the pattern is expected to be found in the frame.
seq-num <seq-num>	Sequence number of the frame.
src-mac <mac-addr>	Source MAC address in the 802.11 frame header.
valid-ap	Matches a valid AP SSID.

Example

The following command configures a signature profile:

```
(host) [mynode] (config) #ids signature-profile floor4
(host) [mynode] (IDS Signature Profile "floor4") #frame-type assoc
(host) [mynode] (IDS Signature Profile "floor4") #src-mac 00:00:00:00:00:00
```

Description

This command configures detection of unauthorized devices, as well as rogue AP detection and containment. Unauthorized device detection includes the ability to detect and disable rogue APs and other devices that can potentially disrupt network operations.

Parameter	Description
<code><profile-name></code>	Name that identifies an instance of the profile. 1-63 characters
<code>adhoc-using-valid-ssid-quiet-time</code>	Time to wait, in seconds, after detecting an ad hoc network using a valid SSID, after which the check can be resumed. 60-360000 seconds 900 seconds
<code>allow-well-known-mac</code>	Allows devices with known MAC addresses to classify rogues APs. Depending on your network, configure one or more of the following options for classifying rogue APs: <ul style="list-style-type: none">▪ hsrp: Routers configured for HSRP, a Cisco proprietary redundancy protocol, with the HSRP MAC OUI 00:00:0c.▪ iana: Routers using the IANA MAC OUI 00:00:5e.▪ local-mac: Devices with locally administered MAC addresses starting with 02.▪ vmware: Devices with any of the following VMWare OUIs: 00:0c:29, 00:05:69, or 00:50:56▪ vmware1: Devices with VMWare OUI 00:0c:29.▪ vmware2: Devices with VMWare OUI 00:05:69.▪ vmware3: Devices with VMWare OUI 00:50:56. If you modify an existing configuration, the new configuration overrides the original configuration. For example, if you configure <code>allow-well-known-mac hsrp</code> and then configure <code>allow-well-known-mac iana</code> , the original configuration is lost. To add more options to the original configuration, include all of the required options, for example: <code>allow-well-known-mac hsrp iana</code> .

Parameter	Description
	<p>Use caution when configuring this command. If the neighboring network uses similar routers, those APs might be classified as rogues. If containment is enabled, clients attempting to associate to an AP classified as a rogue are disconnected through a denial of service attack.</p> <p>To clear the well known MACs in the system, use the following commands:</p> <ul style="list-style-type: none"> ▪ <code>clear wms wired-mac</code>: This clears all of the learned wired MAC information on Mobility Conductor. ▪ <code>reload</code>: This reboots Mobility Conductor.
<code>cfg-valid-11a-channel <channel></code>	<p>List of valid 802.11a channels that third-party APs are allowed to use.</p> <p>34-165</p>
<code>cfg-valid-11g-channel <channel></code>	<p>List of valid 802.11b/g channels that third-party APs are allowed to use.</p> <p>1-14</p>
<code>classification</code>	<p>Enables or disables rogue AP classification. A rogue AP is one that is unauthorized and plugged into the wired side of the network. Any other AP seen in the RF environment that is not part of the valid enterprise network is considered to be interfering — it has the potential to cause RF interference but it is not connected to the wired network and thus does not represent a direct threat.</p>
<code>clone <source></code>	<p>Name of an existing IDS rate thresholds profile from which parameter values are copied.</p>
<code>detect-adhoc-network</code>	<p>Enables or disables detection of ad hoc networks.</p>
<code>detect-adhoc-using-valid-ssid</code>	<p>Enables or disables detection of ad hoc networks using valid or protected SSIDs.</p>
<code>detect-bad-wep</code>	<p>Enables or disables detection of WEP initialization vectors that are known to be weak or repeating. A primary means of cracking WEP keys is to capture 802.11 frames over an extended period of time and search for implementations that are still used by many legacy devices.</p>
<code>detect-ht-greenfield</code>	<p>Enables or disables detection of high-throughput devices advertising greenfield preamble capability.</p>

Parameter	Description
<code>detect-invalid-mac-oui</code>	Enables or disables checking of the first three bytes of a MAC address, known as the organizationally unique identifier (OUI), assigned by the IEEE to known manufacturers. Often clients using a spoofed MAC address do not use a valid OUI and instead use a randomly generated MAC address. Enabling MAC OUI checking causes an alarm to be triggered if an unrecognized MAC address is in use.
<code>detect-misconfigured-ap</code>	Enables or disables detection of misconfigured APs. An AP is classified as misconfigured if it is classified as valid and does not meet any of the following configurable parameters: <ul style="list-style-type: none"> ▪ valid channels ▪ encryption type ▪ list of valid AP MAC OUIs ▪ valid SSID list
<code>detect-sta-assoc-to-rogue</code>	Enables or disables detection of station association to rogue AP.
<code>detect-unencrypted-valid-client</code>	Enables or disables detection of unencrypted valid clients.
<code>detect-valid-client-misassociation</code>	Enables or disables detection of misassociation between a valid client and an unsafe AP. This setting can detect the following misassociation types: <ul style="list-style-type: none"> ▪ MisassociationToRogueAP ▪ MisassociationToExternalAP ▪ MisassociationToHoneypotAP ▪ MisassociationToAdhocAP ▪ MisassociationToHostedAP
<code>detect-valid-ssid-misuse</code>	Enables or disables detection of Interfering or Neighbor APs using valid or protected SSIDs.
<code>detect-wifi-direct-p2p-groups</code>	Enables or disables detection of WIFI-Direct P2P groups.
<code>detect-windows-bridge</code>	Enables or disables detection of Windows station bridging.
<code>detect-wireless-bridge</code>	Enables or disables detection of wireless bridging.
<code>detect-wireless-hosted-network</code>	If enabled, this feature can detect the presence of a wireless hosted network. When a wireless hosted network is detected this feature sends a "Wireless Hosted Network" warning level security log message and the <i>wlsxWirelessHostedNetworkDetected</i> SNMP trap.

Parameter	Description
	If there are clients associated to the hosted network, this feature will send a "Client Associated To Hosted Network" warning level security log message and the <i>wlsxClientAssociatedToHostedNetworkDetected</i> SNMP trap.
ignore-adhoc-awdl-networks	Ignore or process frames from adhoc AWDL networks.
mac-oui-quiet-time	Time, in seconds, that must elapse after an invalid MAC OUI alarm has been triggered before another identical alarm may be triggered. 60-360000 seconds 900 seconds
no	Negates any configured parameter.
oui-classification	Enables or disables OUI based rogue AP classification.
overlay-classification	Enables or disables overlay rogue AP classification.
privacy	Enables or disables encryption as a valid AP configuration.
prop-wm-classification	Enables or disables rogue AP classification through propagated wired MACs.
protect-adhoc-enhanced	Enable or disable advanced protection from open or WEP ad hoc networks. When enhanced ad hoc containment is carried out, a new repeatable event, syslog and SNMP trap will be generated for each containment event.
protect-adhoc-network	Enable or disable protection from ad hoc networks using WPA or WPA2 security. When ad hoc networks are detected, they are disabled using a DoS attack.
protect-adhoc-using-valid-ssid	Enable or disable protection from ad hoc networks using valid or protected SSIDs.
protect-high-throughput	Enable or disable protection of high-throughput (802.11n) devices.
protect-ht-40mhz	Enable or disable protection of high-throughput (802.11n) devices operating in 40 MHz mode.
protect-misconfigured-ap	Enable or disable protection of misconfigured APs.

Parameter	Description
protect-ssid	Enable or disable use of SSID by valid APs only.
protect-valid-sta	When enabled, does not allow valid stations to connect to a non-valid AP.
protect-wifi-direct-p2pgroups	Enable or disable protection from WIFI-Direct P2P Groups.
protect-windows-bridge	Enable or disable protection of a windows station bridging
protect-wireless-hosted-network	<p>When you enable the wireless hosted network protection feature, Mobility Conductor enforces containment on a wireless hosted network by launching a denial of service attack to disrupt associations between a Windows 7 software-enabled Access Point (softAP) and a client, and disrupt associations between the client that is hosting the softAP and any access point to which the host connects.</p> <p>When a wireless hosted network triggers this feature, wireless hosted network protection sends the Wireless Hosted Network Containment and Host of Wireless Network Containment warning level security log messages, and the <i>wlsxWirelessHostedNetworkContainment</i> and <i>wlsxHostOfWirelessNetworkContainment</i> SNMP traps.</p> <p>NOTE: The existing generic containment SNMP traps and log messages will also be sent when Wireless Hosted Network Containment or Host of Wireless Network Containment is enforced.</p>
require-wpa	When enabled, any valid AP that is not using WPA encryption is flagged as misconfigured.
rogue-containment	Rogue APs can be detected (see classification) but are not automatically disabled. This option automatically shuts down rogue APs. When this option is enabled, clients attempting to associate to an AP classified as a rogue are disconnected through a denial of service attack.
suspect-rogue-conf-level <suspect-rogue-conf-level>	<p>Confidence level of suspected Rogue AP to trigger containment.</p> <p>When an AP is classified as a suspected rogue AP, it is assigned a 50% confidence level. If multiple APs trigger the same events that classify the AP as a suspected rogue, the confidence level increases by 5% up to 95%.</p>

Parameter	Description
	<p>In combination with suspected rogue containment, this option configures the threshold by which containment should occur. Suspected rogue containment occurs only when the configured confidence level is met.</p> <p>50-100%</p> <p>60%</p>
suspect-rogue-containment	<p>Suspected rogue APs are treated as interfering APs, thereby Mobility Conductor attempts to reclassify them as rogue APs. Suspected rogue APs are not automatically contained. In combination with the configured confidence level (see suspect-rogue-conf-level), this option contains the suspected rogue APs.</p>
unencrypted-valid-client-quiet-time <unencrypted-valid-client-quiet-time>	<p>Time to wait, in seconds, after detecting an unencrypted valid client after which the check can be resumed.</p> <p>60-360000 seconds</p> <p>900 seconds</p>
valid-and-protected-ssid <ssid>	List of valid and protected SSIDs.
valid-oui <valid-oui>	List of valid MAC OUIs.
valid-wired-mac <valid-wired-mac>	List of MAC addresses of wired devices in the network, typically gateways or servers.
vendor-specific-ie-exclusion <oui> <oui type>	<p>Configures exclusions for IDS containment based on vendor specific IE information. This feature allows APs to be exempted from containment even when the devices use randomized MAC addresses. ArubaOS allows for a maximum of five vendor OUI and OUI types to be defined for confinement exclusion.</p>
wifi-direct-network-quiet-time	<p>Time to wait in seconds after detecting a WIFI-Direct network, after which the check can be resumed. Minimum is 60 seconds</p>
wireless-bridge-quiet-time <wireless-bridge-quiet-time>	<p>Time, in seconds, that must elapse after a wireless bridge alarm has been triggered before another identical alarm may be triggered.</p> <p>60-360000 seconds</p> <p>900 seconds</p>

Parameter	Description
wireless-hosted-network-quiet-time <wireless-hosted-network-quiet-time>	The wireless hosted network detection feature sends a log message and trap when a wireless hosted network is detected. The quiet time defined by this parameter sets the amount of time, in seconds, that must elapse after a wireless hosted network log message or trap has been triggered before an identical log message or trap can be sent again. 60-360000 seconds 900 seconds

Example

The following command copies the settings from the `ids-unauthorized-device-disabled` profile and then enables detection and protection from ad hoc networks:

```
(host) [mynode] (config) #ids unauthorized-device-profile floor7
(host) [mynode] (IDS Unauthorized Device Profile "floor7") #unauth1
(host) [mynode] (IDS Unauthorized Device Profile "floor7") #clone ids-
unauthorized-device-disable
(host) [mynode] (IDS Unauthorized Device Profile "floor7") #detect-adhoc-
network
(host) [mynode] (IDS Unauthorized Device Profile "floor7") #protect-adhoc-
network
```

```

Description

This command configures the IDS WLAN management system (WMS) general profile. The WLAN management system (WMS) on Mobility Conductor monitors wireless traffic to detect any new AP or wireless client station in the RF environment. When an AP or wireless client is detected, it is classified, and its classification is used to determine the security policies that should be enforced on the AP or client.

By default, non-Aruba APs that are connected on the same wired networks as Aruba APs are classified as “rogue” APs. Enabling AP learning classifies non-Aruba APs as “valid” APs. Typically, you would want to enable AP learning in environments with large numbers of existing non-Aruba APs and leave AP learning enabled until all APs in the network have been detected and classified as valid. Then, disable AP learning and reclassify any unknown APs as interfering.

VLAN Trunking

In deployments where Aruba APs are not placed on every VLAN and where it is *not* possible to trunk all VLANs to an Aruba AP, enable the parameter **learned-system-wired-mac**. When this is enabled, ArubaOS is able to classify rogues on all the VLANs that belong to a Mobility Conductor, as long as Aruba APs can see the rogues in the air. If there are VLANs in the network residing on a third party controller and if those VLANs are trunked to a port on a Mobility Conductor, enabling this feature will allow detection of rogues on those VLANs as well.

Mobility Conductor/Managed Device

When **learned-system-wired-mac** is enabled in a Mobility Conductor deployment, the learning of Wired and Gateway MACs will happen at each managed device. For topologies with managed devices in different geographical locations, the managed device collects the Wired and Gateway MAC info and passes it to the APs that are connected to it. Even though the locals do the collection of Wired and Gateway MACs, Mobility Conductor is still responsible for classification.

Parameter	Description
adhoc-ap-ageout-interval <adhoc-ap-ageout-interval>	Time, in minutes, that an ad hoc (IBSS) AP remains unseen before it is deleted (ageout) from the database. 0-10000 30 minutes
ap-ageout-interval <ap-ageout-interval>	Time, in minutes, that an AP remains unseen by any probes before it is deleted from the database. 0-10000 30 minutes
collect-stats	Enables or disables collection of statistics (up to 25,000 entries) on Mobility Conductor for monitored APs and clients.
detect-phony-bssid	Enable or disable phony BSSID detection.
learn-ap	Enables or disables "learning" of non-Aruba APs.
learn-system-wired-macs	Enables or disables "learning" of wired MACs.
no	Negates any configured parameter.
persistent-neighbor	Does not age out known AP neighbors.
persistent-valid-sta	Does not age out valid stations.
phony-bssid-quiet-time <phony-bssid-quiet-time>	Specify phony BSSID quiet time in minutes.
poll-interval <poll-interval>	Interval, in milliseconds, for communication between Mobility Conductor and Aruba AMs. Mobility Conductor contacts the AM at this interval to download AP to station associations, update policy configuration changes, and download AP and station statistics. 60000 milliseconds (1 minute)
poll-retries <poll-retries>	Maximum number of failed polling attempts before the polled AM is considered to be down. 2
propagate-wired-macs	Enable/disable propagation of the gateway wired MAC information.
sta-ageout-interval <sta-ageout-interval>	Time, in minutes, that a client remains unseen by any probes before it is deleted from the database. 30 minutes
stat-update	Enable/disable statistics updating in the database.

Example

The following command enables AP learning:

```
(host) [mynode] (IDS WMS General Profile) #learn-ap
```

The following command disables AP learning:

```
(host) [mynode] (IDS WMS General Profile) #no learn-ap
```

```

Description

This command configures the WLAN management system (WMS) service to terminate on individual managed devices instead of Mobility Conductor.

The WLAN management system (WMS) on the controller monitors wireless traffic to detect any new AP or wireless client station in the RF environment. When an AP or wireless client is detected, it is classified, and its classification is used to determine the security policies that should be enforced on the AP or client. By default, the WMS service is terminated at Mobility Conductor, which requires every AP across the network to communicate with the WMS service on Mobility Conductor. The IDS WMS local system profile includes a WMS service termination override parameter that optimizes limited bandwidth between the managed device and Mobility Conductor by allowing the AP communicate directly with the managed device to which it is associated.

When local WMS service termination is enabled, the WMS service on the managed device will:

- Perform device classification for associated APs
- Correlate events from associated APs
- Update the local WMS database
- Aggregate and redistribute WMS data such as wired MAC addresses, tarpit BSSIDs and valid or registered OUIs to associated APs

The devices and events detected by the managed device can (optionally) be sent to Mobility Conductor, allowing Mobility Conductor to update its database with AP, client and event information from that managed device. Note, however, that enabling this option increases the bandwidth usage between the managed device and Mobility Conductor.

The configuration parameters in IDS WMS local system profile enables local termination of the WMS service, sets maximum thresholds for the maximum number of managed APs and stations, and defines the intervals at which valid AP, rogue AP and station data is sent to the managed device. Increasing the max AP or max station threshold limits in the IDS local system profile will cause an increase in usage in the memory by WMS. In general, each entry will consume about 500 bytes of memory. If a setting is bumped up by 2000, then it will cause an increase in WMS memory usage by 1 MB.

Parameter	Description
max-ap-threshold	Sets the max threshold for the total number of APs. 0 to 50,000,000
max-rbtree-entries	Sets the max threshold for the total number of AP and station RBTREE entries.
max-sta-threshold	Sets the max threshold for the total number of stations.
max-system-wm	Sets the max number of system wired MAC table entries learned by the managed device. 1-2000 1000
no	Negates or deletes an existing parameter
override-svc-termination	Overrides the system-determined termination mode, and terminates WMS service at the managed device to which the AP is associated. Do not use this option if you have multiple managed devices in one location, as WMS will not operate correctly.
periodic-ap-snapshot-interval	Sets the interval, in minutes, at which to generate a periodic snapshot of monitored APs. The (AMON) messages comprising the snapshot are spread over this interval. 60-360 minutes 180 minutes
periodic-rogue-ap-snapshot-interval	Sets the interval, in minutes, at which to generate a periodic snapshot of monitored rogue APs. The (AMON) messages comprising the snapshot are spread over this interval. 5-360 minutes 30 minutes
periodic-sta-snapshot-interval	Sets the interval, in minutes, at which to generate a periodic snapshot of monitored clients. The (AMON) messages comprising the snapshot are spread over this interval. 60-360 minutes 180 minutes
system-wm-update-interval	Sets the interval, in minutes, for repopulating the system wired MAC table at the managed device. 1-30 minutes 8 minutes

Example

The following commands first set the interval time for repopulating the MAC table to 10 minutes and then sets the maximum number of APs to 100:

```
(host) [mynode] (config) #ids wms-local-system-profile system-wm-update-  
interval 10  
(host) [mynode] (config)# ids wms-local-system-profile max-ap-threshold 100
```

ifmap

```
ifmap cppm
  enable
  no
  server host <host>
    port <port>
      username<username>
      passwd <password>
```

Description

This command is used in conjunction with ClearPass Policy Manager. It sends HTTP User Agent Strings and mDNS broadcast information to ClearPass Policy Manager so that it can make more accurate decisions about what types of devices are connecting to the network.

Parameter	Description
enable	Enables the IFMAP protocol.
server	Configures the ClearPass Policy Manager IF-MAP server.
host <host>	IP address or hostname of the ClearPass Policy Manager IF-MAP server.
port <port>	Port number for the ClearPass Policy Manager IF-MAP server. 1-65535 443
username <username>	Username for the user who performs actions on the ClearPass Policy Manager IF-MAP server. The name must be between 1-255 bytes in length.
passwd <password>	Password of the user who performs actions on the ClearPass Policy Manager IF-MAP server. The password must be between 6-100 bytes in length.

Example

This example configures IFMAP and enables it.

```
(host) [md] (config) #ifmap
(host) [md] (config) #ifmap cppm
(host) [md] (CPPM IF-MAP Profile) #server host <host>
(host) [md] (CPPM IF-MAP Profile) #port <port>
(host) [md] (CPPM IF-MAP Profile) #passwd <psswd>
(host) [md] (CPPM IF-MAP Profile) #enable
```

interface cellular

```
interface cellular ip access-group session <name>
interface cellular ip nat outside
interface cellular bandwidth-contract {app | appcategory} <appname>
    <STRING> [upstream | downstream]
interface cellular bandwidth-contract exclude [app | appcategory]
    <appname>
interface cellular bandwidth-contract <STRING> [upstream | downstream]
interface cellular transmit max-rate {kbits | mbits}
```

Description

This command allows you to specify an ingress or egress ACL to the cellular interface of an EVDO modem.

Parameter	Description
<code>interface cellular</code>	Configures the cellular interface.
<code>ip access-group session <name></code>	Enter the name or number of the access group you want to apply to the EVDO modem.
<code>ip nat outside</code>	Source NAT all traffic routed from this cellular interface.
<code>bandwidth-contract {app appcategory exclude <STRING>}</code>	Configures the egress bandwidth contract for the physical interface.
<code><appname></code>	Specifies the app name or the app category name.
<code>upstream</code>	Apply the bandwidth-contract to upstream.
<code>downstream</code>	Apply the bandwidth-contract to downstream.
<code>transmit max-rate {kbits mbits}</code>	Specify transmit rate-limit configuration in kbits or mbits.

Example

```
(host) [mynode](config-submode)#ip access-group session 3
(host) [mynode](config-submode)#bandwidth-contract app myapp bc1
downstream
```

```

Description

This command configures a GigabitEthernet interface. Use this command to configure settings for Mobility Conductor interface, including duplex, LLDP and switchport settings. You can issue the **show port status** command to obtain information about the interfaces currently available on the Mobility Conductor.

Interface Bandwidth Contracts

7000 Series controllers have the ability to classify and identify applications on the network. You can create bandwidth contracts to limit traffic for individual applications (or categories of applications) either sent from or received by a selected interface. There are two basic models for using this feature.

■ **Limiting lower-priority traffic:** If there is a lower-priority application or application type that you want to limit, apply a bandwidth contract just to that application, and allow all other application traffic to pass without any limits.

Protecting higher-priority traffic: If you want to guarantee bandwidth for a company-critical application or application group, you can add that application to an exception list, then apply a bandwidth contract to all remaining traffic.

You can apply bandwidth contracts using one or both of these models. Each interface supports up to 64 bandwidth contracts.

Interface contract Precedence

An interface bandwidth contract is applied to downstream traffic before a user-role bandwidth contract is applied, and for upstream traffic, the user-role bandwidth contract is applied before the interface bandwidth contract. For all traffic using compression and encryption, bandwidth contracts are applied after that traffic is compressed and encrypted. If you apply more than one bandwidth contract to any specific category type, then the bandwidth contracts are applied in the following order:

A contract that explicitly excludes an application

A contract that explicitly excludes an application category

A contract that applies to a specific application

A contract that applies to a specific application category

A generic bandwidth contract, not specific to any application or application category

Parameter	Description
<code><slot/module/port></code>	Interface in <code><slot>/<module>/<port></code> format.
<code>bandwidth-contract</code>	Apply a bandwidth contract to all upstream of downstream traffic, or to traffic for a specified application or application category
<code><name></code>	Name of a bandwidth contract configured with the aaa bandwidth-contract command. If you specify a bandwidth contract name <i>before</i> you specify an application or application category, the bandwidth contract is applied to all downstream or upstream traffic.
<code>app <name></code>	Name of the application to which the bandwidth contract is applied. For a complete list of supported applications, issue the command <code>show dpi application all</code> .
<code>appcategory <name></code>	Name of the application category to which the bandwidth contract is applied. For a complete list of supported applications, issue the command <code>show dpi application category all</code> .

Parameter	Description
<code>downstream</code>	Apply the bandwidth contract to downstream traffic.
<code>upstream</code>	Apply the bandwidth contract to upstream traffic.
<code>exclude</code> <code><app> <appcategory></code>	Use this parameter to exclude application or application category traffic from a bandwidth contract.
<code>dac-alternate-linkup</code>	Enables alternate configuration to bring up link of DAC. Required for some DAC cables.
<code>description</code>	String that describes this interface.
<code>duplex</code>	Transmission mode on the interface: full or half-duplex or auto to automatically adjust transmission. <code>auto/full/half</code> <code>auto</code>
<code>ip access-group</code>	Applies the specified ACL to the interface. Use the <code>ip access-list</code> command to configure an ACL. This parameter requires the PEFNG license.
<code>in</code>	Applies ACL to interface's inbound traffic.
<code>out</code>	Applies ACL to interface's outbound traffic.
<code>session</code>	Applies session ACL to interface and optionally to a selected VLAN associated with this port.
<code>jumbo</code>	Enables or disables jumbo frame MTU configured via firewall on a port. <code>disabled</code>
<code>lACP</code>	Configure an LACP group to the interface.
<code>group <id> mode</code> <code>[active passive]</code>	Enter the LAG number (0-7) and specify the mode (active or passive). <ul style="list-style-type: none"> ■ Active mode—the interface is in active negotiating state. LACP runs on any link that is configured to be in the active state. The port in an active mode also automatically initiates negotiations with other ports by initiating LACP packets. ■ Passive mode—the interface is not in

Parameter	Description
	<p>an active negotiating state. LACP runs on any link that is configured in a passive state. The port in a passive mode responds to negotiations requests from other ports that are in an active state. Ports in passive state respond to LACP packets.</p>
port-priority	<p>Enter the port-priority value. The higher the value, the lower the priority.</p> <p>1-65535 255</p>
timeout	<p>Enter the keyword long to set the LACP session to 90 seconds. Enter the keyword short to set the LACP session to 3 seconds.</p> <p>90</p>
lldp	<p>Configures an LLDP functionality on an interface.</p>
fast-transmit-counter	<p>Set the number of the LLDP data units sent each time fast LLDP data unit transmission is triggered.</p> <p>1-8 4</p>
fast-transmit-interval	<p>Set the LLDP fast transmission interval in seconds.</p> <p>1-3600 1</p>
med	<p>Enables the LLDP MED protocol.</p> <p>disabled</p>
proprietary neighbor discovery	<p>Configures proprietary neighbor discovery.</p>
receive	<p>Enables processing of LLDP PDU received.</p> <p>disabled</p>
sys-tlv disable	<p>Disables system TLV options.</p> <p>enabled</p>
transmit	<p>Enables LLDP PDU transmit.</p> <p>disabled</p>

Parameter	Description
transmit-hold <1-100>	Set the transmit hold multiplier. 1-100 4
transmit-interval <1-3600>	Sets the transmit interval in seconds. 1-3600 30
no	Negates any configured parameter.
openflow-disable	Enables or disables Openflow on Gigabit Ethernet. disabled
poe	Enables PoE on the interface. enabled
cisco	Enables Cisco-style PoE on the interface. disabled
port monitor gigabitethernet port-channel	Monitors another interface on the managed device.
priority-map	Applies a priority map to the interface. Use the <code>priority-map</code> command to configure a priority map which allows you to map ToS and CoS values into high priority traffic queues.
sfp-alternate-detection	Enables detection of SFP+ via alternative communications protocol. This parameter is required for some SFP+ transceivers.
shutdown	Causes a hard shutdown of the interface.
spanning-tree	Enables Rapid spanning tree or Per-VLAN spanning tree. enabled
bpduguard	Enables bpduguard on the edge ports. disabled
cost	Administrative cost associated with the spanning tree. The cost prioritizes routing to the destination. The lower the cost, the higher the priority. 1-65535

Parameter	Description
	4
point-to-point	Set interface as point to point. disabled
port-priority	Spanning tree priority of the interface. A lower setting brings the port closer to root port position (favorable for forwarding traffic) than does a higher setting. This is useful if ports may contend for root position if they are connected to an identical bridge. 1-255 1.28
portfast	Enables forwarding of traffic from the interface. disabled
vlan	Configure a VLAN instance or a range of VLAN IDs for spanning tree. 1-4094 disabled
speed	Sets the interface speed: 10 Mbps, 100 Mbps, 1000 Mbps, or auto configuration. 10 100 1000 auto auto
speed-mode {10Gbps 1Gbps 40Gbps }	Sets the interface speed-mode to one of the following values: <ul style="list-style-type: none"> ▪ 10 Gbps- - You can configure this on the ports, G0/0/0, G0/0/4, G0/0/8, and G0/0/12. ▪ 1 Gbps- - You can configure this on the ports, G0/0/8 and G0/0/12. ▪ 40 Gbps- - You can configure this on the ports, G0/0/0 and G0/0/4. The port range details are as follows: <ul style="list-style-type: none"> ▪ G0/0/0 - When applied on this port, the speed change is applicable to the port range 0/0/0 - 0/0/3. ▪ G0/0/4 - When applied on this port, the speed change is applicable to the port range 0/0/4 - 0/0/7. ▪ G0/0/8 - When applied on this port, the

Parameter	Description
	<p>speed change is applicable to the port range 0/0/8 - 0/0/11.</p> <ul style="list-style-type: none"> ■ G0/0/12 - When applied on this port, the speed change is applicable to the port range 0/0/12 - 0/0/15. <p>10 1 40</p> <p>NOTE: This parameter is applicable only to Aruba 7280 controllers.</p> <p>NOTE: You must reboot the controller after configuring this parameter.</p>
switchport	Sets switching mode parameters for the interface.
access vlan <id>	Sets the interface as an access port for the specified VLAN. The interface carries traffic only for the specified VLAN.
mode {access trunk}	<p>Sets the mode of the interface to access or trunk mode only.</p> <p>access trunk</p> <p>access</p>
<pre>port-security maximum <num> [level [[drop] [logging] [shutdown interval <seconds>]]</pre>	<p>Sets the port security parameters such as the maximum number of addresses that can be configured on the port. Upon exceeding the maximum limit, the port drops the packets on the port.</p> <p>You can also set one of the following levels for dropping the packets on exceeding the limit:</p> <ul style="list-style-type: none"> ■ drop—drops the packets ■ logging—drops the packets and records a message in the log file. This is the default level. ■ shutdown—drops the packet, records a log message, and shuts the port down for the specified time interval.

Parameter	Description
<pre>trunk {allowed vlan {<vlans> add <vlans> all except <vlans> remove <vlans> <WORD>} native vlan <vlan>}}</pre>	<p>Sets the interface as a trunk port for the specified VLANs. A trunk port carries traffic for multiple VLANs using 802.1q tagging to mark frames for specific VLANs. You can include all VLANs configured on the managed device, or add or remove specified VLANs. You can also remove all the VLANs from the list of allowed VLANs configured on a trunk port. Specify native to identify the native VLAN for the trunk mode interface. Frames on the native VLAN are not 802.1q tagged.</p>
<pre>transmit max-rate mbits <txrate> scheduler-profile <profile-name></pre>	<p>Sets a maximum transmit rate in Mbps and assigns a scheduler profile. Allowed range for maximum transmit rate is 1-100 Mbps.</p>
<pre>trusted</pre>	<p>Set this interface and range of VLANs to be trusted. VLANs not included in the trusted range of VLANs will be, by default, untrusted. Trusted ports and VLANs are typically connected to internal controlled networks, while untrusted ports connect to third-party APs, public areas, or other networks to which access controls should be applied. When Aruba APs are attached directly to the managed device, set the port to be trusted.</p> <p>enabled</p>
<pre>vlan <word></pre>	<p>Sets the supplied range of VLANs as trusted. All remaining become untrusted automatically.</p> <p>For example, If you set a VLAN range as: vlan 1-10, 100-300, 301, 305-400, 501-4094 Then all VLANs in this range are trusted and all others become untrusted by default. You can also use the <code>no trusted vlan</code> command to explicitly make an individual VLAN untrusted. The <code>no trusted vlan</code> command is additive and adds given vlans to the existing untrusted vlan set.</p> <p>However, if you execute the <code>trusted vlan <word></code> command, it overrides any earlier untrusted VLANs or a range of untrusted VLANs and creates a new set of trusted VLANs.</p> <p>A port supports a user VLAN range from 1-4094. If you want to set all VLANs (1-4094) on a port as untrusted then mark the port itself as untrusted. By default the port and all its associated VLANs are trusted.</p> <p>1-4094</p>

Parameter	Description
tunneled-node-port	Enable tunneled node capability on the interface. disabled
xsec	Enables and configures the Extreme Security (xSec) protocol. NOTE: You must purchase and install the xSec software module license in the Mobility Conductor.
point-to-point	MAC address of the managed device that is the xSec tunnel termination point, and the 16-byte shared key used to authenticate the managed device to each other. The key must be the same on both managed device.
allowed vlan	VLANs that are allowed on the xSec tunnel.
mtu	(Optional) MTU size for the xSec tunnel.
vlan	xSec VLAN ID. For managed device-to-managed device communications, both managed device must belong to the same VLAN. 1-4094

Example

The following commands configure an interface as a trunk port for a set of VLANs:

```
(host) [mynode] (config) # interface gigabitethernet 0/0/0
(host) [mynode] (config-range)# switchport mode trunk
(host) [mynode] (config-range)# switchport trunk native vlan 10
(host) [mynode] (config-range)# switchport trunk allowed vlan 1,10,100
```

The following commands configure trunk port 0/0/0 with test-acl session for VLAN 2.

```
(host) [mynode] (config) # interface range gigabitethernet 0/0/0
(host) [mynode] (config-range)# switchport mode trunk
(host) [mynode] (config-range)# ip access-group
(host) [mynode] (config-range)# ip access-group test session vlan 2
```

The following commands configure a interface bandwidth contract for a high-priority application.

```
(host) [mynode] (config) # interface gigabitethernet 0/0/1
```

```
(host) [mynode] (config) # bw-contract protectskype4b exclude app alg-  
skype4b-voice downstream
```

Related Commands

Command	Description
<code>show interface gigabitethernet</code>	Displays information about a specified Gigabit Ethernet port.

Command History

Release	Modification
ArubaOS 8.3.0.0	A new parameter, <code>speed-mode</code> , was added.
ArubaOS 8.2.0.0	The following changes were introduced: <ul style="list-style-type: none">■ Updated the new syntax as ip access-group {in out session {vlan <vlanId>}} <name>■ A new sub parameter <WORD> was added under <code>switchport trunk allowed</code> parameter. You can specify none to remove all the VLANs from the list of allowed VLANs configured on the trunk port.■ A new parameter, <code>sfp-alternate-detection</code>, was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	This command is available in the base operating system. The <code>ip access-group</code> parameter requires the PEFNG license. The xsec parameter requires the xSec license.	Config mode on Mobility Conductor.

interface loopback

```
interface loopback
  ip address <ipaddr>
  ipv6 address <ipv6-prefix>
  no ...
```

Description

This command configures the loopback address on Mobility Conductor. If configured, the loopback address is used as Mobility Conductor's IP address. If you do not configure a loopback address for Mobility Conductor, the IP address assigned to VLAN 1 is used as Mobility Conductor's IP address. After you configure or modify a loopback address, you need to reboot Mobility Conductor.

Parameter	Description
ip address	Host IP address in dotted-decimal format. This address is routed from all external networks.
ipv6 address	Host IPv6 address that can be routed from all external networks.
no	Negates any configured parameter.

Example

The following command configures a loopback address:

```
(host) [mynode] (config) #interface loopback
(host) [mynode] (config-submode)#ip address 10.2.22.220
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

interface mgmt

```
interface mgmt
  dhcp
  ip address <ipaddr> <ipmask> [vlan-tag <vlanid>]
  ipv6 address <ipaddr>/<prefix-length> [vlan-tag <vlanid>]
  no ...
  shutdown
```

Description

This command configures the out-of-band Ethernet management port on controller.

Syntax

Parameter	Description
dhcp	Enables DHCP on the interface. NOTE: This parameter is available only for AOS version 8.9 or earlier.
ip address	Configures an IP address and netmask on the interface.
vlan-tag <vlanid>	(Optional) Tags the management interface with the specified VLAN ID.
ipv6 address <ipaddr>	Configures an IPv6 address on the interface.
vlan-tag <vlanid>	(Optional) Tags the management interface with the specified VLAN ID.
no	Negates any configured parameter.
shutdown	Causes a hard shutdown of the interface.

Usage Guidelines

Execute this command on the device level from the Mobility Conductor. This command is applicable only for the 7000 Series platforms.

Use the **show interface mgmt** command to view the current status of the management port.

Example

The following command configures an IP address on the management interface:

```
(host) [mynode] (config) #interface mgmt
(host) [mynode] (config-submode) #ip address 10.1.1.1 255.255.255.0
```

Command History

Release	Modification

interface port-channel

```
interface port-channel <id>
  description <LINE>
  gigabitethernet <slot/module/port>
  ip access-group {in <name>|out <name>|session <name>|vlan <vlanId> {session
<name>}}
  jumbo
  no ...
  openflow-disable
  shutdown
  spanning-tree [bpduguard|cost <value>|point-to-point|port-priority
<value>|portfast [trunk]|vlan {range <WORD>|<vlanid>}}
  switchport {access vlan <vlan>|mode {access|trunk}|trunk {allowed vlan
<vlans>|add <vlans>|all|except <vlans>|remove <vlans>| native vlan <vlan>}
  trusted {vlan [add|remove] <word>}
  xsec {{point-to-point <macaddr> <key> allowed vlan <vlans> [<mtu>}}|vlan <vlan>}
```

Description

This command configures an Ethernet port channel.

A port channel allows you to aggregate ports on a managed device. You can configure a maximum of 8 port channels per supported managed device with a maximum of 8 interfaces per port channel.

Note the following when setting up a port channel between a managed device and a Cisco switch (such as a Catalyst 6500 Series Switch):

- There must be no negotiation of the link parameters.
- The port-channel mode on the Cisco switch must be “on”.

Parameter	Description
<id>	ID number for this port channel. 0-7
description <LINE>	A character string describing this port-channel. up to 60 characters
gigabitethernet <slot/module/port>	Adds the specified GigabitEthernet interface to the port channel.
ip <access-group>	Applies the specified ACL to the interface. Use the <code>ip access-list</code> command to configure an ACL. This command requires the PEFNG license.

Parameter	Description
<code>in <name></code>	Applies ACL to interface's inbound traffic.
<code>out <name></code>	Applies ACL to interface's outbound traffic.
<code>session <name></code>	Applies session ACL to interface and optionally to a selected VLAN associated with this port.
<code>vlan <vlanId> {session <name>}</code>	Applies session ACL to VLAN. 1-4094
<code>jumbo</code>	Enables or disables jumbo frame MTU configured via firewall on a port channel. Disabled
<code>no</code>	Negates any configured parameter.
<code>openflow-disable</code>	Enables or disables Openflow on the port channel. Disabled NOTE: This parameter is available only for AOS version 8.9 or earlier.
<code>shutdown</code>	Causes a hard shutdown of the interface.
<code>spanning-tree</code>	Enables spanning tree.
<code>bpduguard</code>	Enables BPDU guard on the port channel. Disabled
<code>cost <value></code>	Specify the cost value of the spanning tree path for an interface. 1 - 65535
<code>point-to-point</code>	Configures the interface as a point to point link.
<code>port-priority <value></code>	Specify the spanning tree priority for the interface. 1 - 255
<code>portfast [trunk]</code>	Enables forwarding of traffic from the interface. Optionally you can choose a trunk port for forwarding the traffic.
<code>vlan {range <WORD> <vlanid>}}</code>	Configure a VLAN instance or a range of VLAN IDs for the

Parameter	Description
switchport	Sets switching mode parameters for the interface.
access vlan <vlanId>	Sets the interface as an access port for the specified VLAN. The interface carries traffic only for the specified VLAN.
mode {access trunk}	Sets the mode of the interface to access or trunk mode only.
port-security maximum <num>	Sets the maximum number of MAC addresses that can be configured on the port channel. 16-32768
trunk {allowed vlan {<vlans> add <vlans> all except <vlans> remove <vlans>} native vlan <vlan>}}	Sets the interface as a trunk port for the specified VLANs. A trunk port carries traffic for multiple VLANs using 802.1q tagging to mark frames for specific VLANs. You can include all VLANs configured on the managed device, or add or remove specified VLANs. Optionally you can specify the native VLAN for the trunk mode interface. Frames on the native VLAN are not 802.1q tagged.
trusted	Set this interface and range of VLANs to be trusted. VLANs not included in the trusted range of VLANs will be, by default, untrusted. Trusted ports and VLANs are typically connected to internal controlled networks, while untrusted ports connect to third-party APs, public areas, or other networks to which access controls should be applied. When Aruba APs are attached directly to a managed device, set the port to be trusted. disabled
vlan [add remove] <word>	Sets the specified range of VLANs as trusted. All remaining become untrusted automatically. For example, if you set a VLAN range as: vlan 1-10, 100-300, 301, 305-400, 501-4094 Then all VLANs in this range are trusted and all others become untrusted by default. You can also use the <code>no trusted vlan</code> command to explicitly make an individual VLAN untrusted. The <code>no trusted vlan</code> command is additive and adds given vlans to the existing untrusted vlan set.

Parameter	Description
	<p>However, if you execute the <code>trusted vlan <word></code> command, it overrides any earlier untrusted VLANs or a range of untrusted VLANs and creates a new set of trusted VLANs.</p> <p>A port supports a user VLAN range from 1-4094. If you want to set all VLANs (1-4094) on a port as untrusted then mark the port itself as untrusted. By default the port and all its associated VLANs are trusted.</p> <p>1-4094</p>
<code>xsec</code>	<p>Enables and configures the Extreme Security (xSec) protocol.</p> <p>You must purchase and install the xSec software module license in the managed device.</p>
<code>point-to-point</code>	<p>MAC address of the device that is the xSec tunnel termination point, and the 16-byte shared key used to authenticate the device to each other. The key must be the same on both devices.</p>
<code>allowed vlan</code>	VLANs that are allowed on the xSec tunnel.
<code>mtu</code>	(Optional) MTU size for the xSec tunnel.
<code>vlan</code>	<p>xSec VLAN ID. For managed device-to-managed device communications, both managed devices must belong to the same VLAN.</p> <p>1-4094</p>

Example

The following command configures a port channel:

```
(host) (config) #interface port channel 7
(host) [mynode] (config-submode) #gigabitethernet 0/0/1
(host) [mynode] (config-submode) #gigabitethernet 0/0/2
```

Command History

Release	Modification
ArubaOS 8.2.0.0	Updated the new syntax as ip access-group {in <name> out <name> session <name> vlan <vlanId> {session <name>}} .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

interface range

```
interface range gigabitethernet <slot>/<module-start>/<port-start>-<module-
end>/<port-end>
  ip access-group {in|out|session {vlan <vlanId>}} <acl>_name>
  lacp
  lldp
  no
  shutdown
  switchport {access vlan <vlan>|mode {access|trunk}|trunk {allowed vlan
<vlans>|add <vlans>|all|except <vlans>|remove <vlans>}|
  native vlan <vlan>}}
  trusted {vlan <word>}
```

Description

This command configures a range of GigabitEthernet interfaces on the managed device.

Parameter	Description
range	Range of Ethernet ports in the format <slot>/<module>/<port>-<port>. where <slot>/<module>/<port> is the interface.
duplex	Transmission mode on the interface: full- or half-duplex or auto to automatically adjust transmission. auto/full/half auto
ip access-group	Applies the specified ACL to the interface. Use the ip access-list command to configure an ACL.
in	Applies ACL to interface's inbound traffic.
out	Applies ACL to interface's outbound traffic.
session	Applies session ACL to interface and optionally to a selected VLAN associated with this range of ports.
lacp	Configure an LACP group to the interface.
group <id> mode [active passive]	Enter the LAG number (0-7) and specify the mode (active or passive). 1. Active mode—the interface is in active negotiating state. LACP runs on any link

Parameter	Description
	<p>that is configured to be in the active state. The port in an active mode also automatically initiates negotiations with other ports by initiating LACP packets.</p> <p>2. Passive mode—the interface is not in an active negotiating state. LACP runs on any link that is configured in a passive state. The port in a passive mode responds to negotiations requests from other ports that are in an active state. Ports in passive state respond to LACP packets.</p>
<code>port-priority <value></code>	<p>Enter the port-priority value. The higher the value, the lower the priority.</p> <p>1-65535 255</p>
<code>timeout</code>	<p>Enter the keyword long to set the LACP session to 90 seconds. Enter the keyword short to set the LACP session to 3 seconds.</p> <p>90</p>
<code>lldp</code>	<p>Configures an LLDP functionality on an interface.</p>
<code>fast-transmit-counter</code>	<p>Set the number of the LLDP data units sent each time fast LLDP data unit transmission is triggered.</p> <p>1-8 4</p>
<code>fast-transmit-interval</code>	<p>Set the LLDP fast transmission interval in seconds.</p> <p>1-3600 1</p>
<code>med</code>	<p>Enables the LLDP MED protocol.</p> <p>disabled</p>
<code>receive</code>	<p>Enables processing of LLDP PDU received.</p> <p>disabled</p>
<code>transmit</code>	<p>Enables LLDP PDU transmit.</p>

Parameter	Description
	disabled
transmit-hold <1-100>	Set the transmit hold multiplier. 1-100 4
transmit-interval <1-3600>	Sets the transmit interval in seconds. 1-3600 30
no	Negates any configured parameter.
shutdown	Causes a hard shutdown of the interface.
switchport	Sets switching mode parameters for the interface.
access vlan	Sets the interface as an access port for the specified VLAN. The interface carries traffic only for the specified VLAN.
mode	Sets the mode of the interface to access or trunk mode only.
trunk {allowed vlan {<vlans> add <vlans> all except <vlans> remove <vlans>} native vlan <vlan>}}	Sets the interfaces as trunk ports for the specified VLANs. A trunk port carries traffic for multiple VLANs using 802.1q tagging to mark frames for specific VLANs. You can include all VLANs configured on the managed device, or add or remove specified VLANs. Optionally you can specify the native VLAN for the trunk mode interface. Frames on the native VLAN are not 802.1q tagged.
trusted	Set this interface and range of VLANs to be trusted. VLANs not included in the trusted range of VLANs will be, by default, untrusted. Trusted ports and VLANs are typically connected to internal controlled networks, while untrusted ports connect to third-party APs, public areas, or other networks to which access controls should be applied. When Aruba APs are attached directly to the managed device, set the port to be trusted. enabled
vlan <word>	Sets the specified range of VLANs as trusted. All remaining become untrusted automatically.

Parameter	Description
	<p>For example, If you set a VLAN range as: vlan 1-10, 100-300, 301, 305-400, 501-4094 Then all VLANs in this range are trusted and all others become untrusted by default. You can also use the no trusted vlan command to explicitly make an individual VLAN untrusted. The no trusted vlan command is additive and adds given vlans to the existing untrusted vlan set.</p> <p>However, if you execute the trusted vlan <word> command, it overrides any earlier untrusted VLANs or a range of untrusted VLANs and creates a new set of trusted VLANs.</p> <p>1-4094</p> <p>NOTE: A port supports a user VLAN range from 1-4094. If you want to set all VLANs (1-4094) on a port as untrusted then mark the port itself as untrusted. By default the port and all its associated VLANs are trusted.</p>

Example

The following command configures a range of interface as a trunk port for a set of VLANs:

```
(host) [00:0b:86:99:88:17] (config) #interface range gigabitethernet 0/0/0-0/17
(host) [00:0b:86:99:88:17] (config-submode)#switchport mode trunk
(host) [00:0b:86:99:88:17] (config-submode)#switchport trunk native vlan 10
(host) [00:0b:86:99:88:17] (config-submode)#switchport trunk allowed vlan 1,10,100
```

Description

This command configures a Layer-2 or Layer-3 GRE tunnel between a managed device and another GRE-capable device. The default is an IPv4 Layer-3 GRE tunnel (**tunnel mode gre ip**).

In Layer-3 GRE tunnels, IPv6 encapsulated in IPv4 and IPv4 encapsulated in IPv6 are not supported. The only Layer-3 GRE modes supported are IPv4 encapsulated in IPv4 and IPv6 encapsulated in IPv6.

You can direct traffic into the tunnel using a static route (by specifying the tunnel as the next hop for a static route) or a session-based ACL.

Parameter	Description
<code><number></code>	<p>Tunnel Identification number.</p> <p>The tunnel ID used here does not have to match the tunnel ID used in the other managed device.</p> <p>1-16777215</p>
<code>autogenerate peer <peer-mac-address></code>	<p>Auto generates the tunnel endpoint for the specified peer device.</p>
<code>description</code>	<p>String that describes this tunnel.</p>
<code>inter-tunnel-flooding</code>	<p>Enables inter-tunnel flooding.</p> <p>Enabled</p>
<code>ip access group in <acl-name></code>	<p>Attach a route ACL to a L3 GRE tunnel interface.</p> <p>When you associate a routing ACL to inbound traffic on a managed device terminating a L3 GRE tunnel, that ACL can forward traffic as normal, route traffic to a nexthop router on a nexthop list, or redirect traffic over an L3 GRE tunnel or tunnel group. For more information on creating a routing ACL, see ip access-list route.</p>
<code>ip address</code> <code>{internal pool tunnel-pool <pool-name></code> <code> {<ipaddr> <netmask>}}</code>	<p>IP address of the Layer 3 tunnel. This represents the entrance to the tunnel.</p> <p>NOTE: This address</p>

Parameter	Description
	<p>should be a unique, non-routable IP address.</p> <p>Enter one of the following values:</p> <ul style="list-style-type: none"> ▪ internal: IP address is allocated from the Remote-Node pool. ▪ pool tunnel-pool <pool-name>: IP address is allocated from the specified tunnel pool. ▪ <ipaddr>: An IPv4 address. <p>NOTE: The IP address should not be part of any subnet in your network, nor does it have to be routable in your network. It is used as a gateway for routing your private subnets (i.e., non-routable VLANs) within the GRE tunnel.</p> <ul style="list-style-type: none"> ▪ <netmask>: IP subnet mask.
ipv6	<p>IPv6 address of the Layer-3 GRE tunnel.</p> <p>NOTE: This IP address can be configured only for a Layer-3 GRE tunnel (refer to the "<i>mode gre</i>" parameter below for details).</p>

Parameter	Description
mtu	MTU size for the interface. 1024 - 9216 Enabled, IPv4: 1100, IPv6: 1500
no	Negates any configured parameter.
openflow-enable	Enables OpenFlow on the tunnel. Disabled
shutdown	Causes a hard shutdown of the interface.
trusted [vlan {add <word>} {remove <word>} <word>]	<ul style="list-style-type: none"> ■ When Trusted is enabled: Any device can send any traffic through the GRE tunnel without having to be authenticated. Trusted VLANs are supported on a single Layer-2 GRE tunnel. ■ Use vlan add <word> to add VLANs to the current trusted list. Disabled <p>NOTE: <word> represents a VLAN range.</p> <ul style="list-style-type: none"> ■ Use vlan remove <word> to remove VLANs from the current trusted list. <p>NOTE: <word></p>

Parameter	Description
	<p>represents a VLAN range.</p> <ul style="list-style-type: none"> ■ When Trusted is disabled: <p data-bbox="1208 447 1398 1115">Any device that is a source of traffic and is sent through the tunnel must be authenticated to be able to send the traffic. If the device is not authenticated, traffic from that device will be subject to the restrictions of the Initial Role specified in the Wired Access AAA Profile. This is the default. Untrusted VLANs are supported on a single Layer-2 GRE tunnel.</p> <p data-bbox="1170 1119 1386 1228">For related information, see aaa authentication wired.</p>
tunnel	<p>Configures tunneling. The default is an IPv4 Layer-3 GRE tunnel.</p> <pre data-bbox="1170 1381 1317 1413">mode gre ip</pre>
destination <ip-addr> {ipv6 <ipv6-addr>}	<p>The destination IP address (IPv4 or IPv6) for the GRE tunnel endpoint.</p>
keepalive icmp	<p>Enables sending periodic ICMP (ping) keepalive frames on the tunnel to determine the status of the tunnel (up or down).</p>

Parameter	Description
	Disabled
<ipaddr>	IP address of the ping destination.
<next-hop>	<p>Router IP address belonging to any of the L2 GRE tunnel - vlans . This parameter is mandatory only for L2 GRE tunnel.</p> <p>Disabled</p>
<pre>keepalive cisco {<interval> <retries>}</pre>	<p>Enables sending of periodic keepalive frames on the tunnel to determine the tunnel status (up or down). You can optionally set the interval at which keepalive frames are sent, and the number of times the frames are resent before a tunnel is considered to be down.</p> <p>Disabled</p> <p>NOTE: Executing the <code>no tunnel keepalive</code> command disables the keepalive frames, but retains the configured interval and retry values.</p>

Parameter	Description
	<p>The <cisco> option enables keepalive interoperability for Layer-3 tunnels between managed devices and Cisco network devices. Aruba sets the keepalive packet's GRE protocol field to 0x801; however, Cisco sets the GRE protocol field to 0. When the cisco option is enabled, the Arubamanaged device automatically sets the GRE protocol value to 0.</p> <p>The <interval> option sets the number of seconds at which the keepalive frames are sent. Range is 1 second to 86400 seconds and default is 10 seconds.</p> <p>The <retries> option sets the number of consecutive times that the keepalives fail before the tunnel is considered to be down. Range is 0 to 1024 and default is 3.</p>
<pre>mode gre {ip ipv6 <num>}</pre>	<p>This parameter specifies the tunnel encapsulation method as GRE and allows you to specify whether it is a Layer-2 or Layer-3 GRE tunnel.</p> <ul style="list-style-type: none"> ■ ip: Specifies an IPv4 Layer-3 GRE tunnel. The protocol number is set to 0x0800 and is not configurable.

Parameter	Description
	<p>Traffic is redirected into the tunnel using a static route or a session ACL policy. The managed device encapsulates the Layer-3 packet only.</p> <ul style="list-style-type: none"> ■ ipv6: Specifies an IPv6 Layer-3 GRE tunnel. The protocol number is set to 0x86DD and is not configurable. Traffic is redirected into the tunnel using a static route or a session ACL policy. The managed device encapsulates the Layer-3 packet only. ■ <num>: A 16-bit protocol number that uniquely identifies a GRE tunnel. The number format is numeric. The managed devices at both endpoints of the tunnel must be configured with the same protocol number. The protocol number does not necessarily have to match the protocol number of the encapsulated frame. The managed device encapsulates the entire frame, including the

Parameter	Description
	Layer-2 header.
<pre> source controller-ip ipv6 {controller-ip loopback {vlan <vlanid>} <ipv6-addr>} loopback {vlan <vlanid>} <ip-addr> </pre>	<p>The local endpoint of the tunnel on the controller. This can be one of the following:</p> <ul style="list-style-type: none"> ■ controller-ip: IPv4 address of the managed device. ■ ipv6: Specify one of the following IPv6 options: <ul style="list-style-type: none"> ■ controller-ip: Specify the IPv6 address of the managed device. ■ loopback: Specify the IPv6 loopback interface configured on the managed device. ■ vlan <vlan -id>: Specify the VLAN interface ID. ■ <ipv6-addr>: Specify the IPv6 address. ■ loopback: Specify the loopback interface configured on the managed device. ■ vlan <vlanid>: Specify the VLAN interface ID. ■ <ip-addr>: Specify an IPv4 address.

Parameter	Description
<pre>vlan {add <word> remove <word> <word>}</pre>	<p>Specify the VLANs to be included in this tunnel.</p> <ul style="list-style-type: none"> ■ add <word>: The VLANs to be added to the current list. Separate the VLANs by a comma (,) ■ remove <word>: The VLANs to be removed from the current list. Separate the VLANs by a comma (,) ■ <word>: The VLANs that should be part of the current list. Separate the VLANs by a comma (,) <p>NOTE: You can configure a VLAN only if the tunnel mode is set to Layer-2 (mode gre <16-bit protocol number>). If the tunnel mode is not set to Layer-2 mode, the system displays an error message: <i>Tunnel is an IP [v6] GRE Tunnel. Change the mode before adding this.</i></p>

Examples

Layer-2 GRE Tunnel

The following CLI command configures a Layer-2 GRE tunnel:

MN-1 Configuration

```
(host) [mynode] (config)# interface tunnel 101
description "IPv4 Layer-2 GRE 101"
tunnel mode gre 1
tunnel source vlan 101
tunnel destination 192.168.1.1
tunnel keepalive
trusted
tunnel vlan 101
trusted vlan 101
```

MN-2 Configuration

```
(host) [mynode] (config)# interface tunnel 201
description "IPv4 Layer-2 GRE 201"
tunnel mode gre 1
tunnel source vlan 201
tunnel destination 192.168.2.1
tunnel keepalive
trusted
tunnel vlan 201
trusted vlan 201
```

IPv4 Layer-3 GRE Tunnel

The following CLI command examples configure a Layer-3 GRE tunnel for IPv4 between two managed devices.

MN-1 Configuration

```
(MN-1) (host) [mynode] (config) #interface tunnel 301
(host) [mynode] (config-submode) #description "IPv4 L3 GRE 301"
(host) [mynode] (config-submode) #tunnel mode gre ip
(host) [mynode] (config-submode) #ip address 192.1.1.1 255.255.255.255
(host) [mynode] (config-submode) #tunnel source vlan 301
(host) [mynode] (config-submode) #tunnel destination 20.20.20.249
(host) [mynode] (config-submode) #tunnel vlan 301
(host) [mynode] (config-submode) #trusted vlan 301
```

MN-2 Configuration

```
(MN-2) (host) [mynode] (config) #interface tunnel 401
(host) [mynode] (config-submode) #description "IPv4 L3 GRE 401"
(host) [mynode] (config-submode) #tunnel mode gre ip
(host) [mynode] (config-submode) #ip address 168.1.1.2 255.255.255.255
(host) [mynode] (config-submode) #tunnel source vlan 401
```

```
(host) [mynode] (config-submode) #tunnel destination 10.10.10.249
(host) [mynode] (config-submode) #tunnel vlan 401
(host) [mynode] (config-submode) #trusted vlan 401
```

IPv6 Layer-3 GRE Tunnel

The following CLI command examples configure a Layer-3 GRE tunnel for IPv6 between two managed devices.

MN-1 Configuration

```
(MN-1) (host) [mynode] (config) #interface tunnel 501
(host) [mynode] (config-submode) #description "IPv6 Layer-3 GRE 501"
(host) [mynode] (config-submode) #tunnel mode gre ipv6
(host) [mynode] (config-submode) #ip address 2001:1:2:1::1
(host) [mynode] (config-submode) #tunnel source vlan 501
(host) [mynode] (config-submode) #tunnel destination 2001:1:2:2020::1
(host) [mynode] (config-submode) #tunnel vlan 501
(host) [mynode] (config-submode) #trusted vlan 501
```

MN-2 Configuration

```
(MN-2) (host) [mynode] (config) #interface tunnel 601
(host) [mynode] (config-submode) #description "IPv6 Layer-3 GRE 601"
(host) [mynode] (config-submode) #tunnel mode gre ipv6
(host) [mynode] (config-submode) #ip address 2001:1:2:1::2
(host) [mynode] (config-submode) #tunnel source vlan 601
(host) [mynode] (config-submode) #tunnel destination 2001:1:2:1010::1
(host) [mynode] (config-submode) #tunnel vlan 601
(host) [mynode] (config-submode) #trusted vlan 601
```

Command History

Release	Modification
ArubaOS 8.5.0.0	The <code>keepalive icmp <ipaddr> <next-hop></code> parameter was introduced.
ArubaOS 8.4.0.0	Added the optional sub-parameters <code>vlan {add <word>} {remove <word>} <word></code> to the <code>trusted</code> parameter.
ArubaOS 8.2.0.0	Updated the new syntax as access group in <acl-name> .
ArubaOS 8.0.0.0	Command introduced.

Description

This command configures a VLAN interface. All ports on the managed device are assigned to VLAN 1 by default.

Parameter	Description
vlan	VLAN ID number. 1-4094
bandwidth-contract <name>	Name of the bandwidth contract to be applied to this VLAN interface. When applied to a VLAN, the contract limits both broadcast and multicast traffic. Use the <code>aaa bandwidth-contract</code> command to configure a bandwidth contract.
bcmc-optimization	Enables broadcast and multicast traffic optimization to prevent flooding of broadcast and multicast traffic on VLANs. If this feature is enabled on uplink ports, any managed device-generated Layer-2 packets will be dropped. disabled
description	String that describes this interface. 802.1q VLAN
filter-broadcast-on-helper	Filters DHCP discover broadcast when the helper is configured.
filter-broadcast-on-ipv6-helper	Filters DHCPv6 client multicast packets when the helper is configured.
ip	Configures IPv4 for this interface.
access-group in <acl_name>	Assigns an access list to inbound traffic on the interface, where <name> is the name of an access list. Routing ACL is the only supported ACL type that can be configured on a VLAN Interface. Other ACL types are not supported.
address	Configures the IP address for this interface, which can be one of the following: <ipaddr> <netmask> <ul style="list-style-type: none"> ▪ dhcp-client: use DHCP to obtain the IP address ▪ internal: IP address allocated from the branch group config. ▪ pppoe: use PPPoE to obtain the IP address
helper-address <address>	IP address of the DHCP server for relaying DHCP requests for this interface. If the DHCP server is on the same subnetwork as this VLAN interface, you do not need to configure this parameter.

Parameter	Description
igmp	Enables IGMP proxy or IGMP snooping on this interface. See interface vlan ip igmp for complete details on this parameter.
local-proxy-arp	Enables local proxy ARP.
nat {inside outside}	Enables source NAT for all traffic routed from or to this VLAN. CAUTION: All ports on the managed device are assigned to VLAN 1 by default. Do not enable the nat inside option for VLAN 1, as this will prevent IPsec connectivity between the managed device and its IPsec peers.
ospf	Define an OSPF area. See interface vlan ip ospf for complete details on this parameter.
pppoe-max-segment-site	Configures the TCP MSS in bytes. 128
pppoe-password	Configures the PAP password on the PPPoE Access Concentrator for the switch. 1-80
pppoe-service-name	Configures the PPPoE service name. 1-80
pppoe-username	Configures the PAP username on the PPPoE Access Concentrator for the switch. 1-80
pppoe-gateway-nat <nat-ip>	Use the <nat-ip> sub-parameter to specify a NAT IP address instead of actual PPPoE gateway IP address to configure a default route.
routing	Enables layer-3 forwarding on the VLAN interface. To disable layer-3 forwarding, you must configure the IP address for the interface and specify no ip routing . enabled
ipv6	Configures IPv6 for this interface.
address	Configures the IPv6 address of interface. <ul style="list-style-type: none"> ▪ dhcp6-client - The DHCPv6 is used to obtain an IPv6 address. ▪ link-local - The link local address ▪ pd - The prefix obtained by PD client on uplink. ▪ X:X:X::X/<0-128> - The IPv6 prefix/prefix-length used to configure the global unicast address for

Parameter	Description
	this interface.
dhcp	Configures DHCP for IPv6. <ul style="list-style-type: none"> ▪ pdclient - The IPv6 prefix from a DHCPv6 Prefix delegation server. ▪ server - Configures the DHCPv6 pool for the vlan.
helper-address <address>	IPv6 address of the DHCP server for relaying DHCP requests for this interface. If the DHCP server is on the same subnetwork as this VLAN interface, you do not need to configure this parameter.
mld	Enables MLD on this interface. <ul style="list-style-type: none"> ▪ proxy - Configures MLD proxy on the following interfaces. <ul style="list-style-type: none"> ▪ fastethernet ▪ gigabitethernet <slot/module/port> ▪ port-channel ▪ snooping - Configures the MLD snooping on this interface.
nd {ra reachable-time retransmit-time}	Configures the IPv6 neighbor discovery options. <ul style="list-style-type: none"> ▪ ra - configures the following router advertizement options: <ul style="list-style-type: none"> ◦ dns - Configures IPv6 recursive DNS server ◦ dns-sl - Configures IPv6 recursive DNS server search list ◦ enable - Enables IPv6 RA ◦ hop-limit - Configures RA hop-limit ◦ interval - Configures RA interval ◦ life-time - Configures RA lifetime ◦ managed-config-flag - Enables hosts to use DHCP server for stateful address autoconfiguration ◦ mtu - Configures MTU for RA ◦ other-config-flag - Enables hosts to use DHCP server for other non-address stateful autoconfiguration ◦ preference - Configures a router preference of high/low/medium ◦ prefix - Configures IPv6 RA prefix ▪ reachable-time - Configures neighbor discovery reachable time. By default this field is set to 0. Valid

Parameter	Description
	value - 0-3, 600,000 msec. ■ retransmit-time - Configures neighbor discovery retransmit time. By default this field is set to 0. Valid value - 0-3, 600,000 msec.
no	Negates any configured parameter.
ipv6-relay-option	Applies Relay-Option configuration to the DHCPv6 packets that need to be relayed from the WLAN interface.
mtu	MTU setting for the VLAN. 1024-1500
multimode-auth	MultiMode Authentication Support on VLAN
operstate up	Set the state of the interface to be up.
option-82 {ap-name [essid] mac [essid]}	Allows a DHCP relay agent to insert circuit specific information into a request that is being forwarded to a DHCP server. The managed device, when acting as a DHCP relay agent, needs to be able to insert information about the AP and SSID through which a client is connecting into the DHCP request. Many service providers use this mechanism to make access control decisions. You can include: <ul style="list-style-type: none"> ■ AP name or AP name and ESSID. ■ MAC address or MAC address and ESSID.
shutdown	Causes a hard shutdown of the interface.
suppress-arp	Prevents flooding of ARP broadcasts on all the untrusted interfaces.

Example

The following example configures a VLAN interface:

```
(host) [mynode] (config) #interface vlan 16
(host) [mynode] (config-submode) #ip address 10.26.1.1 255.255.255.0
(host) [mynode] (config-submode) #ip helper-address 10.4.1.22
```

The following example displays the use of extended scope of address range:

```
(host) [mynode] (config) #interface vlan 214
(host) [mynode] (config-submode) #ipv6 address 2014::2/64
```

```
(host) [mynode] (config-submode) #ipv6 nd reachable-time 1000
(host) [mynode] (config-submode) #ipv6 nd retransmit-time 1000
(host) [mynode] (config-submode) #ipv6 nd ra enable
(host) [mynode] (config-submode) #ipv6 nd ra preference high
(host) [mynode] (config-submode) #ipv6 nd ra prefix 2014::/64
(host) [mynode] (config-submode) #operstate up
(host) [mynode] (config-submode) #ipv6 mld snooping
```

The following example configures DNS-SL on the VLAN interface:

```
(host) [md] (config) #interface vlan 1
(host) [md] (config-submode)#ipv6 nd ra dns-sl
abcdefghijklmnopqrstuvwxy123456
```

interface vlan ip igmp

```
interface vlan <vlan>
  ip igmp {proxy {gigabitethernet <slot/module/port>} | port-channel <id>} |
  snooping
```

Description

This command enables IGMP or IGMP snooping on this interface, or configures a VLAN interface for uninterrupted streaming of multicast traffic.

The newer IGMP proxy feature and the older IGMP snooping feature cannot be enabled at the same time, as both features add membership information to multicast group table. For most multicast deployments, you should enable the IGMP Proxy feature on all VLAN interfaces to manage all the multicast membership requirements on the managed device. If IGMP snooping is configured on some of the interfaces, there is a greater chance that multicast information transfers may be interrupted.

This release of ArubaOS supports version 1 of the MLD protocol (MLDv1). MLDv1, defined in RFC 2710, is derived from version 2 of the IPv4 IGMPv2. You can use the command `interface vlan <vlan> ipv6 mld` to enable the MLD protocol and allow an IPv6 router to discover the presence of multicast listeners on directly-attached links. Use the CLI command `interface vlan <vlan> ipv6 mld snooping` for the Pv6 router to send multicast frames to only those nodes that need to receive them.

Parameter	Description
<code>proxy</code>	Enable IGMP proxy for this interface.
<code>gigabitethernet <slot/module/port></code>	Enable IGMP proxy on the specified GigabitEthernet (IEEE 802.3) interface.
<code>port-channel <id></code>	Enable IGMP proxy on the specified port channel.
<code>snooping</code>	Enable IGMP snooping. The IGMP protocol enables an router to discover the presence of multicast listeners on directly-attached links. Enable IGMP snooping to limit the sending of multicast frames to only those nodes that need to receive them.

Example

The following example configures IGMP proxy for vlan 2. IGMP reports from the managed device would be sent to the upstream router on gigabitethernet port 0/0/3.

```
(host) (conf)# interface vlan 2
```

```
(conf-subif)# ip igmp proxy gigabitethernet 0/0/3
```

interface vlan ip ospf

```
interface vlan <vlan>
  ip ospf
    area
    authentication message-digest
    cost <cost>
    dead-interval <seconds>
    hello-interval <seconds>
    message-digest-key <keyid> <passwd>
    priority <number>
    retransmit-interval <seconds>
    transmit-delay <seconds>
```

Description

This command configures OSPF on the VLAN interface. When configuring OSPF over multiple vendors, use this command to ensure that all routers use the same cost. Otherwise, OSPF may route improperly.

Parameter	Description
area	Enable OSPF on a specific interface by entering the IP address of the router that will use OSPF.
authentication message-digest	Set the OSPF authentication mode to message digest. disabled
cost <cost>	Set the cost associated with the OSPF traffic on an interface. 1 to 65535 1
dead-interval <seconds>	Set the elapse interval (seconds) since the last hello-packet was received from the router. After the interval elapses, the neighboring routers declare the router dead. 1 to 65535 seconds 40
hello-interval <seconds>	Set the elapse interval (seconds) between hello packets sent on the interface. 1 to 65535 seconds 10
message-digest-key <keyid> <passwd>	Enable OSPF MD5 authentication and set the key identification and a character string password.

Parameter	Description
	<keyid> = 1 to 256 No default
priority <number>	Set the priority number of the interface to determine the designated router. 1 to 255 0
retransmit-interval <seconds>	Set the retransmission time between link state advertisements for adjacencies belonging to the interface. Set the time interval long enough to prevent unnecessary retransmissions. 1 to 65535 seconds 5
transmit-delay <seconds>	Set the elapse time before retransmitting link state update packets on the interface. 1 to 65535 seconds 5

iot-manager

```
db-dump {im-db | im-log-db}
dp-optimize {im-db | im-log-db}
export ibeacon-info ap-group <ap-group>
replace-ap {old-ap-mac <old-ap-mac>} { new-ap-mac <new-ap-mac>}
```

Description

The IoT manager process interacts with the IoT database on the Mobility Conductor. Use this command to dump the content of the database to flash memory or repair the database and reclaim unused flash memory.

Parameter	Description
db-dump	This parameter instructs the mongo database to dump the content of the database to flash memory. This process can take time to complete and runs in the background while the command prompt returns.
im-db	This parameter instructs the mongo database to dump all content in the IoT manager database to flash memory.
im-log-db	This parameter instructs the mongo database to dump all content in the log database to flash memory.
dp-optimize	This parameter instructs the mongo database to repair the database and reclaim unused flash space. This process can take time to complete and runs in the background while the command prompt returns.
im-db	This parameter instructs the mongo database to repair all content in the IoT manager database and reclaim unused memory.
im-log-db	This parameter instructs the mongo database to repair all content in the log database and reclaim unused memory.
export ibeacon-info ap-group <ap-group>	This parameter export the iBeacon information of all devices in the specified AP group.
replace-ap	This parameter replaces an old AP of the specified BLE MAC address with a new AP of the specified BLE MAC address. The new AP inherits the ibeacon configuration of old AP.

Parameter	Description
old-ap-mac <old-ap-mac>	This parameter specifies the old AP with its BLE MAC address.
new-ap-mac <new-ap-mac>	This parameter specifies the new AP with its BLE MAC address.

Example

Access the CLI and use the following command to configure the IoT manager:

```
(host) [mynode] #iot-manager db-dump im-db
Dump process started at 2019-04-29 06:47:48. Dump file is im_db_dump.tgz.
Use 'show iot-manager debug db-dump-status' to check the status

(host) [mynode] #iot-manager db-optimize im-log-db
Optimize process started at 2019-04-30 08:57:18. Use 'show iot-manager debug
db-optimize-status' to check the status

(host) [mynode] #iot-manager export ibeacon-info ap-group default

(host) [mynode] #iot-manager replace-ap old-ap-mac 01:02:03:04:05:06 new-ap-
mac aa:ab:ac:ad:ae:af
```

  zigbee-opmode coordinator
```

Description

This command configures or modifies an IoT radio profile.

Parameter	Description
ble-console	Set the BLE console mode.
ble-opmode	Set the BLE operation mode.
ble-txpower	Set the BLE transmission power in dBm.
clone	Copy data from another IoT radio profile.
no...	Removes any existing configuration.
radio-instance	Enables external or internal radio instance.
radio-mode	Enables BLE or ZigBee radio mode.
zigbee-channel	Set the ZigBee scanning channel.
zigbee-opmode	Set the ZigBee coordinator operation mode.

Example

The following example configures an IoT transport profile.

```
(host) [mynode] (config) #iot radio-profile Sample-Zigbee
(host) [mynode] (IoT Radio Profile "Sample-Zigbee") #radio-mode zigbee
(host) [mynode] (IoT Radio Profile "Sample-Zigbee") #zigbee-channel auto

iot-sniffer radio

```
iot-sniffer radio <radio_macaddr> {disable | enable | reset | start | stop}
```

Description

This command configures the IoT sniffer function on the radio of an AP.

Parameter	Description
<code><radio_macaddr></code>	<p>The MAC address of the radio on which the IoT sniffer function is configured. Available options are:</p> <ul style="list-style-type: none"> ▪ disable—Disables the IoT sniffer function.

Parameter	Description
	<ul style="list-style-type: none"> ▪ enable—Enables the IoT sniffer function. ▪ start—Starts capturing the packets based on the following parameters: <ul style="list-style-type: none"> ◦ server—Denotes the IPv4 server IP address or hostname. ◦ port—Denotes the UDP port number. ◦ zigbee-channel—Denotes the zigbee channel ID. Enter a value between 11 to 26. ▪ stop—Stops capturing the packets. ▪ reset—Resets the IoT sniffer function. Use this option if the IoT sniffer function is not working properly or to clear the configuration on the sniffer.

Example

The following example configures an IoT sniffer on the radio:

```
(host) [mynode] #iot-sniffer radio 90:4c:81:b2:81:f0 enable
```

```

Description

This command configures or modifies an IoT transport profile. An IoT transport profile is a global profile that is used to transport BLE information to an endpoint server.

In some cases, the iot transport profile having a serverType that is supported from ArubaOS 8.4.0.0 version onwards will be skipped when downgrading to a previous version. In such cases, the default serverType will be applied. The default serverType applied might not be a valid serverType that corresponds with other parameters configured in the iot transport profile. The operator must manually fix the configuration parameters in the iot transport profile to match the serverType.

Parameter	Description
<code>accessID <accessID></code>	An access ID will grant extended access. Applies only to endpoint type Assa-Abloy.
<code>accessToken <accessToken></code>	Access token. Configure this only if you want to bypass authentication.
<code>ageFilter</code>	Age filter. Devices without recent activity will not be reported.
<code>authentication-mode</code>	Authentication mode to use with authentication server. Available options are: <ul style="list-style-type: none">▪ client-credentials - Use credentials of the client▪ none - Do not use any credentials▪ password - Use password as credentials
<code>authenticationURL <url></code>	Server URL for authentication.
<code>azure-dps-auth-type group-enrollment symmetric-key <key></code>	Symmetric key to enroll devices in a group on the Azure DPS.
<code>azure-dps-id-scope</code>	Azure DPS ID scope for device provisioning.
<code>bleDataForwarding</code>	Enables BLE data forwarding for known devices.
<code>blePeriodicTelemetryDisable</code>	Disable periodic telemetry report.

Parameter	Description
	<p>NOTE: This command only works for telemetry-websocket Server Type.</p>
cellSizeFilter	<p>A proximity filter. Devices outside the cell will not be reported. Size is specified in meters. Setting to 0 disables the cell size filter.</p>
cipher-list	<p>Cipher list to be used for connections between IOT transport profile and third party server.</p>
client-secret	<p>Password to use when authenticating using client credentials.</p>
clientId <id>	<p>This ID identifies the sender to the server.</p>
clone	<p>Copy data from another IoT data profile.</p>
companyIdentifierFilter <filter>	<p>This is a 2-bytes integer, for example, "HPE - 0x011B" or "Wiliot - 0x0500". You can also include an extra byte which indicates the next layer type, like for HPE - 0x011B, 0x08, which means that the device type used is Aruba sensors.</p>
customFadingFactor	<p>When environment type is custom, you can define a fading factor to get the most accurate distance according to your environment.</p> <p>10-40</p>
dataFilter <dataFilter>	<p>A list of numbers to filter the data before reporting to a server. The numbers correspond to protobuf files. For dataFilter values, see DataFilter Values.</p>

Parameter	Description
deviceClassFilter <device>	A list of device class tags to filter the devices included in the reports. You can specify a maximum of 10 device classes.
abilitySmartSensor	ABB ability smart sensor data
all	All BLE data
aruba-beacons	Aruba beacon data
aruba-sensors	Aruba sensor data
aruba-tags	Aruba tag data
assa-abloy	Assa Abloy door lock data
eddystone	Eddystone data
enoccean-sensors	EnOcean sensor data
enoccean-switches	EnOcean switch data
exposure-notification	Exposure notification based on the presence of service UUID 0xFD6F and service data 0xFD6F
google	Google sensor data
ibeacon	iBeacon data
minew	Minew data
mysphera	MySphera data
sbeacon	Sbeacon data
serial-data	Serial data
unclassified	Unclassified data
wifi-assoc-sta	Data of WiFi associated stations
wifi-tags	WiFi RTLS tag data

Parameter	Description
wifi-unassoc-sta	Data of WiFi unassociated stations
wiliot	Wiliot data
zf-tags	ZF tag data
ZSD	ZigBee Socket Device
deviceCountOnly	Send only the aggregated device counts per configured device class
environmentType	Configure the working environment type.
auditorium	Configure the working environment type as auditorium.
custom	Configure a custom working environment type. Optionally, configure customFadingFactor.
office	Configure the working environment type as office.
outdoor	Configure outdoor working environment type.
shipboard	Configure the working environment type as shipboard.
warehouse	Configure the working environment type as warehouse.
include-ap-group	Configure AP groups that use the transport profile.
localNameFilter <filter>	It is a string, that can do string matching. It matches both advertisement and scan response.

Parameter	Description
<code>macOuiFilter <filter></code>	It is a 3 bytes array. Only public MAC address(non-randomized) are considered. For example, 60:C0:BF is MAC OUI of Blyott devices.
<code>movementFilter <threshold></code>	Filters devices that do not change distance. Specified in meters. Applicable only if a cell size is set. Setting to 0 disables the movement filter.
<code>no</code>	Removes any existing configuration.
<code>password <password></code>	Password for authentication.
<code>perFrameFiltering</code>	Applies transport profile filters to each frame rather than on the device. This parameter can be enabled only when the parameter <code>bleDataForwarding</code> is enabled. This parameter is ignored when the parameter <code>bleDataForwarding</code> is disabled. This parameter is disabled by default.
<code>proxy</code>	Information of the proxy server to which the IoT data is sent.
<code>server <servernm> port <portnum></code>	IP address and port number of the proxy server.
<code>user <usernm> password <passwd></code>	Username and password to log in to the proxy server. This parameter is optional.
<code>reportingInterval<interval></code>	Reporting interval in seconds. 5 to 3600 seconds

Parameter	Description
<code>rssiReporting <format></code>	Set the preferred format for RSSI reporting.
<code>average</code>	RSSI averaged over the reporting period
<code>bulk</code>	RSSI Bulk
<code>last</code>	Most Recent RSSI
<code>max</code>	Maximum RSSI measured over the reporting period
<code>smooth</code>	Smoothed RSSI measured over the reporting period
<code>rtlsDestMAC</code>	Set the destination MAC address filter for RTLS tags.
<code>serverType <type></code>	The type of server that is receiving the telemetry stream.
<code>Assa-Abloy</code>	Stream data to Assa Abloy Visionline server.
<code>Azure-IoTHub</code>	Stream data to Azure IoT hub.
<code>Meridian-Asset-Tracking</code>	Stream data to Meridian websocket server.
<code>Meridian-Beacon-Management</code>	POST data to a RESTful Meridian API.
<code>Telemetry-Https</code>	POST data to a RESTful Aruba API.
<code>Telemetry-Websocket</code>	Stream data to a websocket based server.
<code>serverURL <url></code>	Server URL for sending telemetry.
<code>serviceUUIDFilter <filter></code>	It is a 2 bytes integer, and it could be more than one entry. For example, 0x180F is SIG-adopted service UUID.

Parameter	Description
<code>uidNamespaceFilter</code>	A list of UID namespaces to filter devices included in the reports. Applies only Eddystone-UID devices. You can specify a maximum of 10 namespaces.
<code>urlFilter</code>	A list of URL strings to filter devices included in the reports. Applies only Eddystone-URL devices. The string listed here can be partial URL strings. You can specify a maximum of 10 URL strings.
<code>username <user></code>	Username for authentication.
<code>uuidFilter <filter></code>	A list of UUIDs to filter the devices included in the reports. Applies only to iBeacon devices. You can specify a maximum of 10 UUIDs.
<code>usbSerialDeviceTypeFilter <filter></code>	Enables the use to filter serial data based on the USB serial dongle type. The following serial data type can be filtered: <ul style="list-style-type: none"> ▪ EnOcean ▪ OSU ▪ Piera
<code>vendorFilter</code>	A list of list of vendor IDs and vendor names. You can specify a maximum of 5 vendor IDs or vendor names.
<code>ZSDFilter</code>	A list of ZSD to filter the zigbee socket devices.

iot usetransportProfile

```
iot usetransportProfile <iot-profile-name>
```

Description

This command sets an IoT management server profile. You can set up to four management server profiles.

Example

Execute the following command to set an IoT transport profile:

```
(host) [mynode] (config)# iot usetransportProfile sample
```

Related Commands

ip access-list eth

```
ip access-list eth <accname>
deny {<ethertype> [<bits>]|any} [mirror] [position <prio>]
no ...
permit {<ethertype> [<bits>]|any} [mirror] [position <prio>]
```

Description

This command configures an Ethertype ACL. The Ethertype field in an Ethernet frame indicates the protocol being transported in the frame. This type of ACL filters on the Ethertype field in the Ethernet frame header, and is useful when filtering non-IP traffic on a physical port. This ACL can be used to permit IP frames while blocking other non-IP protocols such as IPX or Appletalk.

If you configure the mirror option, define the destination to which mirrored packets are sent in the firewall policy. For more information, see [firewall on page 636](#).

Parameter	Description
<accname>	Define an access list, where <accname> is a name, or a number in the specified range. 200-299
deny	Reject the specified packets, which can be one of the following: <ul style="list-style-type: none">▪ Ethertype in decimal or hexadecimal (0-65535) and optional wildcard (0-65535)▪ any: match any Ethertype Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination, or set the position of the ACL. The default position is last, a position of 1 puts the ACL at the top of the list.
no	Negates any configured parameter.
permit	Allow the specified packets, which can be one of the following: <ul style="list-style-type: none">▪ Ethertype in decimal or hexadecimal (0-65535) and optional wildcard (0-65535)▪ any: match any Ethertype Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination, or set the position of the ACL. The default position is last, a position of 1 puts the ACL at the top of the list.

Example

The following command configures an Ethertype ACL:

```
(host) [mynode] (config) #ip access-list eth 200
(host) [mynode] (config-submode)#permit any mirror position 3
```

ip access-list extended

```
ip access-list extended <accname>
  deny <protocol> <source> <dest>
  ipv6 <protocol> <source> <dest>
  no ...
  permit <protocol> <source> <dest>
```

Description

This command configures an extended ACL. To configure IPv6 specific rules, use the **ipv6** keyword for each rule.

Extended ACLs are supported for compatibility with router software from other vendors. This ACL permits or denies traffic based on the source or destination IP address or IP protocol.

Parameter	Description
extended <accname>	Define an access list, where <accname> is a name, or a number in the specified range. 100-199, 2000-2699
deny	Reject the specified packets.
<protocol>	Protocol, which can be one of the following: <ul style="list-style-type: none">▪ any: any protocol▪ icmp: Internet Control Message Protocol▪ igmp: Internet Gateway Message Protocol▪ tcp: Transmission Control Protocol▪ udp: User Datagram Protocol▪ <0-255>: An IP protocol number between 0-255
<source>	Source, which can be one of the following: <ul style="list-style-type: none">▪ any: any source▪ host: specify a single host IP address▪ A.B.C.D: IPv4 source address and wildcard
<dest>	Destination, which can be one of the following: <ul style="list-style-type: none">▪ any: any destination▪ host: specify a single host IP address▪ A.B.C.D: IPv4 destination address and wildcard
ipv6 <deny permit>	Use the ipv6 keyword to add IPv6 specific rules.
<protocol>	Protocol, which can be one of the following: <ul style="list-style-type: none">▪ any: any protocol▪ icmpv6: Internet Control Message Protocol▪ tcp: Transmission Control Protocol

Parameter	Description
	<ul style="list-style-type: none"> ▪ udp: User Datagram Protocol ▪ <0-255>: An IP protocol number between 0-255
<source>	Source, which can be one of the following: <ul style="list-style-type: none"> ▪ any: any source ▪ host: specify a single host IP address ▪ X:X:X:X:/<0-128>: IPv6 source address and wildcard
<dest>	Destination, which can be one of the following: <ul style="list-style-type: none"> ▪ any: any destination ▪ host: specify a single host IP address ▪ X:X:X:X:/<0-128>: IPv6 destination address and wildcard
no	Negates any configured parameter.
permit	Allow the specified packets.
<protocol>	Protocol, which can be one of the following: <ul style="list-style-type: none"> ▪ any: any protocol ▪ icmp: Internet Control Message Protocol ▪ igmp: Internet Gateway Message Protocol ▪ tcp: Transmission Control Protocol ▪ udp: User Datagram Protocol ▪ <0-255>: An IP protocol number between 0-255
<source>	Source, which can be one of the following: <ul style="list-style-type: none"> ▪ any: any source ▪ host: specify a single host IP address ▪ A.B.C.D: IPv4 source address and wildcard
<dest>	Destination, which can be one of the following: <ul style="list-style-type: none"> ▪ any: any destination ▪ host: specify a single host IP address ▪ A.B.C.D: IPv4 destination address and wildcard

Example

The following command configures an extended ACL:

```
(host) [mynode] (config) #ip access-list extended 100
(host) [mynode] (config-submode) #deny any host 1.1.21.245 any
```

ip access-list geolocation

```
ip access-list geolocation global-geolocation-acl
deny
{[<from>|<to> {anonymous_proxy [log|mirror|position]|any
[log|mirror|position]}|country <STRING>|region <STRING>}]
no ...
permit
{[<from>|<to> {anonymous_proxy [log|mirror|position]|any
[log|mirror|position]}|country <STRING>|region <STRING>}]
```

Description

This command configures a global geolocation ACL.

Parameter	Description
deny <from to>	Reject the specified packets, which can be one of the following: <ul style="list-style-type: none">▪ Packets coming from the source.▪ Packets meant for the destination.
anonymous_proxy <log mirror position>	Match packets from or to an anonymous proxy. It has the following options: <ul style="list-style-type: none">▪ Log if the ACL is applied.▪ Mirror all session packets to datapath or remote destination.▪ Filter position. The position number is in the range of <1-2000>. The default is last, and 1 is first position.
any <log mirror position>	Match any location. It has the following options: <ul style="list-style-type: none">▪ Log if the ACL is applied.▪ Mirror all session packets to datapath or remote destination.▪ Filter position. The position number is in the range of <1-2000>. The default is last, and 1 is first position.
country <STRING>	Match packets from or to a country. The <STRING> denotes country name. NOTE: Use double quotes to specify country names with spaces in the name.

Parameter	Description
<code>region <STRING></code>	<p>Match packets from or to a region. Region denotes the name of a continent and it should be entered in lower-case. Refer the following examples to mention the region string:</p> <ul style="list-style-type: none"> ▪ <code><africa></code> ▪ <code><north-america></code> ▪ <code><south-america></code> ▪ <code><europe></code> ▪ <code><asia></code> ▪ <code><australia></code>
<code>no</code>	<p>Negates any configured parameter.</p>
<code>permit <from to></code>	<p>Allow the specified packets, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ Packets coming from the source. ▪ Packets meant for the destination.

ip access-list mac

```
ip access-list mac <accname>
  deny {<macaddr>[<wildcard>]|any|host <macaddr>} [mirror]
  no ...
  permit {<macaddr>[<wildcard>]|any|host <macaddr>} [mirror]
```

Description

This command configures a MAC ACL. MAC ACLs allow filtering of non-IP traffic. This ACL filters on a specific source MAC address or range of MAC addresses. If you configure the mirror option, define the destination to which mirrored packets are sent in the firewall policy. For more information, see [firewall on page 636](#).

Parameter	Description
mac <accname>	Configures a MAC access list, where <accname> is a name, or a number in the specified range. 700-799, 1200-1299
deny	Reject the specified packets, which can be the following: <ul style="list-style-type: none">▪ any: any packets▪ host: specify a MAC address▪ A:B:C:D:E:F: MAC address and optional wildcard Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination.
no	Negates any configured parameter.
permit	Allow the specified packets, which can be the following: <ul style="list-style-type: none">▪ any: any packets▪ host: specify a MAC address▪ A:B:C:D:E:F: MAC address and optional wildcard Optionally, you can configure the mirror parameter, which mirrors packets to a datapath or remote destination.

Example

The following command configures a MAC ACL:

```
(host) [mynode] (config) #ip access-list mac 700
(host) [mynode] (config-submode) #deny 11:11:11:00:00:00
```

ip access-list route

```
ip access-list route <accname>
  <source> <dest> <service> <action> forward|route {ipsec-map <ipsec-map-name>}|
  {next-hop-list <next-hop-list-name>}|{tunnel <tunnel-id>}|{tunnel-group
  <tunnelgroupname>} [position <position>]
  ipv6 <source> <dest> <service> <action> forward|route > {next-hoplist <next-hop-
  list-name>} [position <position>]
no ...
```

Description

This command configures an ACL for PBR.

PBR is an optional feature that allows packets to be routed based on ACLs configured by the administrator. By default, when a managed device receives a packet for routing, it looks up the destination IP in the routing table and forwards the packet to the nexthop router. If PBR is configured, the nexthop device can be chosen based on a defined ACL.

In a typical deployment scenario with multiple uplinks, the default route only uses one of the uplink next-hops for forwarding packets. If a nexthop becomes unreachable, the packets will not reach their destination. If your deployment uses PBR based on a nexthop list, any of the uplink nexthops could be used for forwarding traffic. This requires a valid ARP entry (Route-cache) in the system for all the PBR nexthops.

IPv6 PBR does not support WAN uplink functionality.

Parameter	Description
route <accname>	Define a route access list, where <accname> is an access list name
<source>	The traffic source, which can be one of the following: <ul style="list-style-type: none">▪ alias<name>: specify the network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases)▪ any: match any traffic▪ description: brief description about this route acl (up to 128 characters in quotes)▪ host <ip-addr>: specify a single host IP address▪ localip: specify the local IP address to match traffic▪ network <ip-addr> <netmask>: specify the IP address and netmask▪ no: negate a command▪ user: represents the IP address of the user

Parameter	Description
	<p>NOTE: Only any, host <ip-addr>, and network <ip-addr> <netmask> options are supported for IPv6 address.</p> <p>NOTE: You cannot configure IPv6 multicast, link-local, unspecified, loopback, and subnet anycast addresses as IPv6 source addresses.</p>
<dest>	<p>The traffic destination, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ alias<name>: specify the network resource (use the netdestination command to configure aliases; use the show netdestination command to see configured aliases) ▪ any: match any traffic ▪ description: brief description about this route acl (up to 128 characters in quotes) ▪ host <ip-addr>: specify a single host IP address ▪ localip: specify the local IP address to match traffic ▪ network <ip-addr> <netmask>: specify the IP address and netmask ▪ user: represents the IP address of the user <p>NOTE: Only any, host <ip-addr>, and network <ip-addr> <netmask> configuration options are supported for IPv6 address.</p> <p>NOTE: You cannot configure IPv6 multicast, link-local, unspecified, loopback, and subnet anycast addresses as IPv6 destination addresses.</p>
<service>	<p>Network service to which the ACL is applied. The service can be one of the following:</p> <ul style="list-style-type: none"> ▪ any: match any traffic ▪ app<string>: application name. (For a complete list of supported applications, issue the command show dpi application all.) ▪ appcategory <string>: application category name. (For a complete list of supported applications, issue the command show dpi application all.) ▪ icmp: Internet Control Message Protocol ▪ tcp <0-65535>: specify the TCP destination port number (0-65535) ▪ tcp source<0-65535>: TCP source port number ▪ udp <0-65535>: UDP destination port number (0-65535) ▪ udp source<0-65535>: UDP source port number

Parameter	Description
	<ul style="list-style-type: none"> ▪ <0-255>: IP protocol number (0-255) ▪ <string>: name of a network service (use the show netservice command to see configured services) <p>NOTE: Only any configuration option is supported for IPv6 address.</p>
<action>	<p>Action if rule is applied, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ forward: Explicitly define an ACL with a forward action to skip PBR for traffic which would otherwise match another PBR rule. ▪ route ipsec-map <ipsec-map-name>: Redirected over a VPN tunnel by specifying the ipsec-map name. For more information on IPsec maps, see crypto-local ipsec-map. ▪ route next-hop-list <next-hop-list-name>: Packets can be routed to a nexthop router on a nexthop list by specifying the nexthop list name. For more information on nexthop lists, see ip nexthop-list. ▪ route tunnel <tunnel-id>: Packets can be redirected over an L3 GRE tunnel. ▪ route tunnel-group <tunnelgroupname>: Packets can be redirected over an L3 GRE tunnel group. For more information on tunnel groups, see tunnel-group. ▪ [position <position>]: (Optional) Specify the position of the forwarding or routing rule. (1 is first, default is last) <p>NOTE: Only route next-hop-list <next-hop-list-name> configuration option is supported for IPv6 address.</p>

Example

The following command configures a routing access list using an IPsec map.

```
(host) [mynode] (config) #ip access-list route pbr1
(host) [mynode] (config-submode) #any any udp 100 route ipsec-map VPN1
```

The following command configures IPv6 rules in routing access list using next-hop list:

```
(host) [mynode] (config) #ip access-list route pbr2
(host) [mynode] (config-submode) #ipv6 any any any route next-hop-list new
```

A PBR ACL can have both IPv4 and IPv6 rules.

ip access-list session

```
ip access-list session <accname>  
  <source> <dest> <service> <action> [<extended action>]  
  ipv6 <source> <dest> <service> <action> [<extended action>]  
no ...
```

Description

This command configures an ACL session. To create IPv6 specific rules, use the **ipv6** keyword. Session ACLs define traffic and firewall policies on the managed device. You can configure multiple rules for each policy, with rules evaluated from top (1 is first) to bottom. The first match terminates further evaluation. Generally, you should order more specific rules at the top of the list and place less specific rules at the bottom of the list. The ACL ends with an implicit deny all. To configure IPv6 rules, use the `ipv6` keyword followed by the regular ACL keywords.

Parameter	Description
<code>session <accname></code>	Define a session ACL, where <accname> is an access list name, or an access list number in the specified range.
<code>description</code>	Brief description about this session ACL (up to 128 characters in quote)
<code>ipv6</code>	Use the <code>ipv6</code> keyword to create IPv6 specific rules.
<code><source></code>	The traffic source, which can be one of the following: <ul style="list-style-type: none">▪ alias: specify the network resource (use the <code>netdestination</code> command to configure aliases; use the <code>show netdestination</code> command to see configured aliases)▪ any: match any traffic▪ description: brief description about this session acl (up to 128 characters in quotes)▪ host: specify a single host IP address▪ ipv6: specify a single host IPv6 address▪ localip: specify the local IP address to match traffic▪ network: specify the IP address and netmask▪ user: represents the IP address of the user▪ userrole: represents the traffic based on user role
<code><dest></code>	The traffic destination, which can be one of the following: <ul style="list-style-type: none">▪ alias: specify the network resource (use the <code>netdestination</code> command to configure aliases; use the <code>show netdestination</code> command to see configured aliases)

Parameter	Description
	<ul style="list-style-type: none"> ▪ any: match any traffic ▪ description: brief description about this session acl (up to 128 characters in quotes) ▪ host: specify a single host IP address ▪ ipv6: specify a single host IPv6 address ▪ localip: specify the local IP address to match traffic ▪ network: specify the IP address and netmask ▪ user: represents the IP address of the user ▪ userrole: represents the traffic based on userrole
<service>	<p>Network service, which can be one of the following:</p> <ol style="list-style-type: none"> 1. IP protocol number (0-255) 2. name of a network service (use the show netservice command to see configured services) 3. any: match any traffic 4. app: application name. (For a complete list of supported applications, issue the command <code>show dpi application all.</code>) 5. appcategory: application category name. (For a complete list of supported applications, issue the command <code>show dpi application all.</code>) 6. icmp: Internet Control Message Protocol 7. tcp destination port number: specify the TCP port number (0-65535) 8. tcp source: TCP/UDP source port number 9. udp: specify the UDP port number (0-65535) 10. web-cc-category: name of a web content category. For the full list of available web content categories, issue the command show web-cc categories. 11. web-cc-reputation: any of the following predefined web content reputation levels: <ul style="list-style-type: none"> ▪ high-risk ▪ low-risk ▪ moderate-risk ▪ suspicious ▪ trustworthy
<action>	<p>Action if rule is applied, which can be one of the following:</p> <ol style="list-style-type: none"> 1. deny: Reject packets. Applicable to both IPv4 and IPv6.

Parameter	Description
	<p>2. dst-nat: Performs destination NAT on packets. Forward packets from source network to destination; re-mark them with destination IP of the target network. This action functions in tunnel/decrypt-tunnel forwarding mode. User should configure the NAT pool in the managed device.</p> <p>3. src-nat: Performs source NAT on packets. Source IP changes to the outgoing interface IP address (implied NAT pool) or from the pool configured (manual NAT pool). This action functions in tunnel/decrypt-tunnel/bridge/split-tunnel forwarding mode.</p> <p>4. dual-nat: Performs both source and destination NAT on packets. Source IP and destination IP is changed as per the NAT pool configured. This action functions in tunnel/decrypt-tunnel forwarding mode. User should configure the NAT pool in the managed device.</p> <p>5. permit: Forward packets. Applicable to both IPv4 and IPv6.</p> <p>6. redirect: Specify the location to which packets are redirected. The following are applicable only to IPv4:</p> <ul style="list-style-type: none"> ▪ Datapath destination ID (0-65535). ▪ esi-group: Specify the ESI server group configured with the esi group command. ▪ tunnel: Specify the ID of the tunnel configured with the interface tunnel command. ▪ webcc-reputation: Assign one of the predefined web content reputation levels to the packets. <p>The following are applicable only to IPv6:</p> <ul style="list-style-type: none"> ▪ tunnel: Specify the ID of the tunnel configured with the interface tunnel command. ▪ tunnel-group: Specify the tunnel-group configured with the interface tunnel command. <p>route: Specify the next hop to which packets are routed, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ dst-nat: Destination IP changes to the IP configured from the NAT pool. This action functions in bridge/split-tunnel forwarding mode. User should configure the NAT pool in the managed device. ▪ src-nat: Performs source NAT on packets. Source IP changes to the outgoing interface IP address (implied NAT pool) or from the pool configured (manual NAT pool). This

Parameter	Description
	action functions in tunnel/decrypt-tunnel/bridge/split-tunnel forwarding mode.
<extended action>	<p>Optional action if rule is applied, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ blacklist/denylist: block user if ACL gets applied. ▪ disable-scanning: pause ARM scanning while traffic is present. Note that you must enable “VoIP Aware Scanning” in the ARM profile for this feature to work. ▪ dot1p-priority: specify 802.1p priority (0-7), where 0 is the lowest priority, and 7 is the highest. ▪ log: generate a log message ▪ mirror: mirror all session packets to datapath or remote destination ▪ If you configure the mirror option, define the destination to which mirrored packets are sent in the firewall policy. For more information, see firewall on page 636. ▪ next-hop-list: Route packet to the next hop in the list. ▪ position: specify the position of the rule (1 is first, default is last) ▪ queue: assign flow to priority queue (high/low) ▪ send-deny-response: if <action> is deny, send an ICMP notification to the source ▪ time-range: specify time range for this rule (configured with time-range command) ▪ tos: specify ToS value (0-63)
no	Negates any configured parameter.

Example

The following CLI configuration shows how pre-classification and post-classification occurs during enforcement.

Each application has an implicit set of ports that are used for communication. In phase 1, if an application ACE entry is hit, the traffic matching this application’s implicit port is allowed (as governed by the application ACE). The DPI engine can monitor the exchange on these ports and determine the application. Once the application is determined, phase 2 occurs when an evaluation is done to determine the final outcome for the session.

The following CLI configuration example is a user role with both the global and role session ACLs:

```
(host) [mynode] (config) #ip access-list session global-sacl
(host) [mynode] (config) #ip access-list session aprpf-employee-sacl
(host) [mynode] (config) #ip access-list session control
```

```
any any app gmail-chat permit
any any app youtube permit
any any any deny
```

This example shows a DPI rule along with a L3/L4 rule with forwarding action in the same ACL.

```
(host) [mynode] (config) #ip access-list session AppRules
any any app Facebook permit tos 45
any any app YouTube deny
any any appcategory peer-to-peer deny
any any tcp 23 permit
network 40.1.0.0/16 any tcp 80 permit tos 60
network 20.1.0.0/16 any tcp 80 src-nat
!
(host) [mynode] (config) #ip access-list session NetRules
network 80.0.0.0/24 any tcp 80 deny
network 60.0.0.0/24 any tcp 80 dual-nat pool <pool1>
network 10.0.0.0/24 any tcp 80 dst-nat
!
(host) [mynode] (config) #user-role Role1
session-acl AppRules
session-acl NetRules
!
```

The following command configures a session ACL with IPv4 and IPv6 address:

```
(host) [mynode] (config) #ip access-list session common
(host) [mynode] (config-sess-common)#host 10.12.13.14 any any permit
(host) [mynode] (config-sess-common)#ipv6 host 11:12:11:11::2 any any permit
```

The following example displays information for an ACL called mylist:

```
(host) [mynode] (config) #show ip access-list mylist
ip access-list session mylist
mylist
-----
Priority  Source  Destination  Service  Application  Action  TimeRange  Log
Expired  Queue  TOS  8021P  Blacklist/Denylist  Mirror  DisScan  IPv4/6
Contract
-----  -----  -----  -----  -----  -----  -----  ---
-----  -----  -----  -----  -----  -----  -----  -----
```

```
1          any    any          app gmail    deny
Low                                     4
```

The following example shows how this local-override netdestination alias is used in the controller:

```
(host) [mynode] (config) #ip access-list session store-override
```

```

(host) [mynode] (config-sess-store-override)#any alias store any permit
(host) [mynode] (config-sess-store-override)#alias store any any deny
(host) [mynode] (config-sess-store-override)#!
(host) [mynode] (config) #show ip interface brief
Interface                IP Address / IP Netmask      Admin  Protocol
vlan 1                   172.72.10.254 / 255.255.255.0  up     up
vlan 55                  55.55.55.1 / 255.255.255.0    up     up
loopback                 unassigned / unassigned      up     up

(host) [md] #show acl acl-table | include dummy-acl
75  session      620      2          3          dummy-acl
    0

(host) [md] #show acl ace-table acl 75

620: any netdest-id: 34  0  0-0  0-0  f1000080001:permit  alias-dst  hits-
table-index 24578
621: netdest-id: 34 any  0  0-0  0-0  f800080001:permit  alias-src  hits-
table-index 24579
622: any any  0  0-0  0-0  f180000:deny

```

The following examples display the use of extended scope of address range:

```
(host) [mynode] (config) #ip access-list session v6-logon-control
```

```

ipv6 user any udp 546 deny
ipv6 any any svc-v6-icmp permit
ipv6 any any svc-v6-dhcp permit
ipv6 any any svc-dns permit
ipv6 any network fc00::/7 any permit
ipv6 any network fe80::/64 any permit

(host) [mynode] (config) #ip access-list session validuser
network 127.0.0.0 255.0.0.0 any any deny
network 169.254.0.0 255.255.0.0 any any deny
network 224.0.0.0 240.0.0.0 any any deny
host 255.255.255.255 any any deny
network 240.0.0.0 240.0.0.0 any any deny
any any any permit
ipv6 host fe80:: any any deny
ipv6 network fc00::/7 any any permit
ipv6 network fe80::/64 any any permit
ipv6 alias ipv6-reserved-range any any deny
ipv6 any any any permit
!

```

The following example displays the use of source NAT to route the local traffic in AP datapath in Split-Tunnel forwarding mode for IPv6 clients:

```

(host) [mynode] (config) #ip access-list session split
ipv6 any any svc-v6-dhcp permit
ipv6 any any svc-dns permit
ipv6 user network fe80::/16 any permit

```

```
ipv6 network fe::80/16 user any permit
ipv6 user any icmpv6 nb-adv permit
ipv6 user any icmpv6 nb-solicitation permit
ipv6 any user icmpv6 rtr-adv permit
ipv6 any user icmpv6 rtr-solicitation permit
ipv6 any any any route src-nat
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.8.0.0	A new sub-parameter is added to capture a brief description of the session ACL.
ArubaOS 8.4.0.0	The output is modified to display the use of source NAT in Split-Tunnel forwarding mode for IPv6 clients.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

ip access-list standard

```
ip access-list standard <acname>
  deny {<ipaddr> <wildcard>|any|host <ipaddr>}
  ipv6 <ipaddr>
  no ...
  permit {<ipaddr> <wildcard>|any|host <ipaddr>}
```

Description

This command configures a standard ACL. Standard ACLs are supported for compatibility with router software from other vendors. This ACL permits or denies traffic based on the source address of the packet.

Parameter	Description
standard <acname>	Define an access list, where <acname> is an access list name, or an access list number in the specified range. 1-99, 1300-1399
deny	Reject the specified packets, which can be the following: <ul style="list-style-type: none">▪ any: any source▪ host: specify a single host IP address▪ A.B.C.D: IPv4 source address and wildcard
ipv6 <deny permit>	Reject or allow the specified packets, which can be the following: <ul style="list-style-type: none">▪ any: any source/destination IPv6 address▪ host: specify a single host IPv6 address▪ X:X:X:X::X/<1-128>: IPv6 source/destination IPv6 address and wildcard
no	Negates any configured parameter.
permit	Allow the specified packets, which can be the following: IP address and optional wildcard any: any packets host: specify a host IP address

Example

The following command configures a standard ACL:

```
(host) [mynode] (config) #ip access-list standard 1
(host) [mynode] (config-submode) #permit host 10.1.1.244
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

ip cp-redirect-address

```
ip cp-redirect-address {disable | <A.B.C.D>}
```

Description

This command configures a redirect address for captive portal. This command redirects wireless clients that are on different VLANs (from the managed device's IP address) to the captive portal on the managed device.

If you have the Next Generation Policy Enforcement Firewall (PEFNG) license installed in the managed device, modify the captive portal session ACL to permit HTTP/S traffic to the destination **cp-redirect-address <A.B.C.D>** instead of **mswitch**. If you do not have the PEFNG license installed in the managed device, the implicit captive-portal-profile ACL is automatically modified when you issue this command.

Parameter	Description
disable	Disables automatic DNS resolution for captive portal.
<A.B.C.D>	Redirect unauthenticated user to this IP address. This address should be routable from all external networks.

Example

The following command configures a captive portal redirect address:

```
(host) ^[mynode] (config) #ip cp-redirect-address disable
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

ip default-gateway

```
ip default-gateway
  import {cell|cell-cost <cost>|dhcp|dhcp-cost <cost>|pppoe|pppoe-cost <cost>}
  mgmt <nexthop>
  <nexthop> [<cost>]
```

Description

This command configures the default gateway for Mobility Conductor or the managed device. You can use this command to set the default gateway to the IP address of the interface on the upstream router or switch to which you connect Mobility Conductor or the managed device. If you define more than one dynamic gateway type, you must also define a cost for the route to each gateway. Mobility Conductor or the managed device will first attempt to obtain a gateway IP address using the option with the lowest cost. If Mobility Conductor and the managed device are unable to obtain a gateway IP address, they will then attempt to obtain a gateway IP address using the option with the next-lowest path cost.

Starting from ArubaOS 8.11.0.0, you can use the `ip default-gateway mgmt <nexthop>` command to configure the default gateway on the OOB management port for 7000 Series controllers.

Starting from ArubaOS 8.9.0.0, you can use the `ip default-gateway mgmt <nexthop>` command to configure the default gateway for dedicated OOB management Ethernet port on 7280 controllers.

Parameter	Description
<code>import</code>	Use a gateway IP address obtained through the cell interface, DHCP or PPPoE. The default gateway is imported into the routing table and removed when the uplink is no longer active.
<code>cell</code>	Use a gateway IP address obtained through the cell interface.
<code>cell-cost <cost></code>	Use the cost for cell interface.
<code>dhcp</code>	Use a gateway IP address obtained DHCP.
<code>dhcp-cost <cost></code>	Use the cost for DHCP interface.
<code>pppoe</code>	Use a gateway IP address obtained through PPPoE.
<code>pppoe-cost <cost></code>	Use the cost for PPPoE interface
<code>mgmt <nexthop></code>	Set the default gateway IP address as the management interface IP address.
<code><nexthop> [<cost>]</code>	IP address of the default gateway and the distance metric of this route.

Example

The following command configures the default gateway for the Mobility Conductor:

```
(host) [mynode] (config) #ip default-gateway 10.1.1.1
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The <code>ip default-gateway mgmt <nextHop></code> command can be used to configure the default gateway on the OOB management port for 7000 Series controllers.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

ip dhcp adaptive

ip dhcp adaptive

Description

This command enables adaptive VLAN assignment based on the DHCP server.

Example

The following command enables adaptive VLAN assignment based on the DHCP server:

```
(host) [mynode] (config) #ip dhcp adaptive
```

Command History

Release	Modification

ip dhcp default-pool

```
ip dhcp default-pool
  private
  public
```

Description

This command configures the DHCP pool type.

Parameter	Description
private	Configure a private DHCP pool.
public	Configure a public DHCP pool.

Example

The following command configures a private DHCP pool:

```
(host) [mynode] (config) #ip dhcp default-pool private
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode

ip dhcp excluded-address

```
ip dhcp excluded-address <low-address> [<high-address>]
```

Description

This command configures an excluded address range for the DHCP server on Mobility Conductor. Ensure that the statically assigned IP addresses are excluded.

Parameter	Description
<low-address>	Low range excluded IP addresses. For example, you can enter the IP address of the Mobility Conductor so that this address is not assigned.
<high-address>	High range excluded IP addresses.

Example

The following command configures an excluded address range:

```
(host) [mynode] (config) #ip dhcp excluded-address 192.168.1.1 192.168.1.255
```

Command History

Release	Modification

ip dhcp increase-lease-limit

ip dhcp increase-lease-limit

Description

This command configures additional DHCP scope that is twice the user limit on specific controller platforms. This feature is disabled by default. This command can be used only in any of the following controller platforms: 7005controller, 7008controller, or 7010controller.

Example

To enable the additional DHCP scope on a controller, execute the following command:

```
(host) (config) #ip dhcp increase-lease-limit
```

Related Commands

ip dhcp load-balance

```
ip dhcp load-balance priority
  round-robin {ipupsell | private | public}
  strict {ipupsell | private | public}
```

Description

This command configures the DHCP pool load balancing priority.

Parameter	Description
round-robin	Enable a round-robin priority.
ipupsell	Configure the DHCP pool as an IP upsell pool.
private	Configure the DHCP pool as private.
public	Configure the DHCP pool as public.
strict	Enable a strict priority.
ipupsell	Configure the DHCP pool as an IP upsell pool.
private	Configure the DHCP pool as private.
public	Configure the DHCP pool as public.

Example

The following command DHCP pool load balancing priority:

```
(host) [mynode] (config) #ip dhcp load-balance priority round-robin private
```

ip dhcp option-82

```
ip dhcp option-82 <xml_file_name>
```

Description

This command configures option-82 information through XML file

Parameter	Description
<xml_file_name>	XML file name specifying option-82 information. NOTE: This file must be uploaded to flash before executing this command.

Example

The following example configures reserved entries with MAC address of the device:

```
(host) [mynode] (config) #ip dhcp option-82
```

ip dhcp pool

```
ip dhcp pool <name>
  default-router <address> [<address2> <address3> <address4> <address5> <address6>
  <address7> <address8>]
  distributed range <startip> <endip> <hosts>
  dns-server {import | switch-gw-ip | <address> [<address2> <address3> <address4>
  <address5> <address6> <address7> <address8>]}
  domain-name <domain>
  lease <days> <hours> <minutes> <seconds>
  netbios-name-server {import | <address> [<address2> <address3> <address4>
  <address5> <address6> <address7> <address8>]}
  network <network-number> {</prefix(1-30)>|<mask>}
  no ...
  option <code> {hex <hex string> | ip <ipaddr> | text <option-string>}
  pooltype {ipupsell | private | public}
  vendor-class-identifier
```

Description

This command configures a DHCP pool on the Mobility Conductor. A DHCP pool should be created for each IP subnetwork for which DHCP services should be provided. DHCP pools are not specifically tied to VLANs, as the DHCP server exists on every VLAN. When Mobility Conductor receives a DHCP request from a client, it examines the origin of the request to determine if it should respond. If the IP address of the VLAN matches a configured DHCP pool, Mobility Conductor answers the request. When a sub-option, **option 5**, is configured, the DHCP server will allocate an address on the subnet specified in the link-selection sub-option.

Parameter	Description
default-router <address>	IP address of the default router for the DHCP client. The client should be on the same subnetwork as the default router. You can specify up to 8 IP addresses.
distributed range	IP address range for the distributed pool.
<startip>	Starting IP address of the address pool.
<endip>	Ending IP address of the address pool.
<hosts>	Number of clients.
dns-server	Configure DHCP DNS server.
import	Use the DNS server address obtained through DHCP or PPPoE.

Parameter	Description
switch-gw-ip	Configure DNS server as Switch Gateway IP address. Use this parameter when Redirect-DNS has to be enabled on the current pool.
<address>	IP address of the DHCP DNS server. You can specify up to 8 IP addresses.
domain-name <domain>	Domain name to which the client belongs.
lease	The amount of time that the assigned IP address is valid for the client. Specify the lease in <days> <hours> <minutes> <seconds>.
netbios-name-server	IP address of the NetBIOS Windows Internet Naming Service (WINS) server, which can be one of the following:
import	Use the NetBIOS name server address obtained through PPPoE or DHCP.
<address>	IP address of the WINS server. You can specify up to 8 IP addresses.
network	Range of addresses that the DHCP server may assign to clients, in the form of <ipaddr> and <netmask> or <ipaddr> and <prefix>.
</prefix(1-30)>	Network prefix.
<mask>	Network mask.
no	Negates any configured parameter.
option	Client-specific option code and IP address. See RFC 2132, "DHCP Options and BOOTP Vendor Extensions".
hex <hex string>	Specify the Hex string. Maximum hex characters allowed is 22.
ip <ipaddr>	Specify IP address.
text <option-string>	Specify optional string.
pooltype	Configure the DHCP Pool types.
ipupsell	Configure the DHCP pool as an IP upsell pool.
private	Configure the DHCP pool as private.
public	Configure the DHCP pool as public.
vendor-class-identifier	Send or suppress the Aruba AP vendor ID to clients.

Example

The following command configures a DHCP pool:

```
(host) [mynode] (config) #ip dhcp pool floor1
(host) [mynode] (config-submode) #default-router 10.26.1.1
(host) [mynode] (config-submode) #dns-server 192.168.1.10
(host) [mynode] (config-submode) #domain-name floor1.test.com
(host) [mynode] (config-submode) #lease 0 8 0
(host) [mynode] (config-submode) #network 10.26.1.0 255.255.255.0
```

Sub-option Example

The following command configures a sub-option for the DHCP option-82:

```
(host) [mynode] (config) #ip dhcp pool default
(host) [mynode] (config-submode)#option
<code>      DHCP option code(range 0-254)
(host) [mynode] (config-submode)#option 5
(host) [mynode] (config-submode)#option 5
hex       Configure hexadecimal option
ip        Configure IPv4 option
text      Configure text option
```

Command History

Release	Modification
ArubaOS 8.4.0.0	The <code>switch-gw-ip</code> sub-parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode

ip dhcp reserved

```
ip dhcp reserved [hardware-address <mac> ip-address <ipv4> hostname <name>]
```

Description

This command configures DHCP server device reservations. You can use IP reservation to manually bind IP addresses from a DHCP pool to a client MAC address.

Parameter	Description
hardware-address <mac>	The 48-bit MAC address of the device.
ip-address <ipv4>	The fixed IPv4 address of the host.
hostname <name>	Hostname of the managed device.

Example

The following example configures reserved entries with MAC address of the device:

```
(host) [mynode] (config) #ip dhcp reserved hardware-address  
ae:ff:ff:ff:ff:ae ip-address 1.2.3.4 hostname aruba
```

Command History

Release	Modification
ArubaOS 8.8.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

ip domain-name

ip domain-name <name>

Description

This command configures the default domain name. Mobility Conductor uses the default domain name to complete hostnames that do not contain domain names. You must have at least one domain name server configured on the controller (see [ip name-server on page 869](#)).

Parameter	Description
<name>	Name used to complete unqualified host names. Do not specify the leading dot (.).

Example

The following command configures the default domain name:

```
(host) [mynode] (config) #ip domain-name yourdomain.com
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ip domain lookup

ip domain lookup

Description

This command enables DNS hostname to address translation. This command is enabled by default. Use the **no** form of this command to disable.

Example

The following command enables DNS hostname translation:

```
(host) [mynode] (config) #ip domain lookup
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ip domain redirect

ip domain redirect

Description

This command enables Domain Name System (DNS) redirect for hostname translation. This command is disabled by default. Use the **no** form of this command to disable.

Example

The following command enables DNS redirect hostname translation:

```
(host) [mynode] (config) #ip domain redirect
```

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ip domain-redirect

```
ip domain-redirect <name> <ip-addr>
```

Description

This command redirects the DNS query matching corporate domain to a dedicated corporate IPv4 DNS server. This command is not enabled by default. Use the **no** form of this command to disable.

Parameter	Description
<name>	Specifies the domain name to be redirected.
<ip-addr>	Specifies the domain server IP address.

Example

The following command redirects the domain to a dedicated DNS server:

```
(host) [mynode] (config) #ip domain-redirect xyzcorp.com 192.168.11.2
```

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platform	License	Command Mode

ip dynamic-dns

```
ip dynamic-dns interval <interval> server <ipaddr> key <key details> dhcp-pool  
<pool-name>  
ip dynamic-dns push server <ipaddr>
```

Description

This command configures DDNS information.

Parameter	Description
push server	Push DDNS server information. This parameter is available in enable mode only.
<ipaddr>	Specify the IP address of the DDNS server.
interval <interval>	Time interval in seconds at which the DNS updates are synced to the server. 0 to 86400 seconds 43200 seconds
server <ipaddr>	IP address of the server
key <key details>	The key details should be entered in algo-name:keyname:keystring format
dhcp-pool <pool-name>	DHCP pool name

Example

```
(host)[mynode] (config) #ip dynamic-dns interval 3500 server 1.1.1.1 key  
hmac-sha1:ddns-key:asdafsdffasdfsfgdsgs= dhcp-pool pool3
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode

ip igmp

```
ip igmp
  last-member-query-count <val>
  last-member-query-interval <last-member-query-interval>
  max-members-per-group <val>
  no
  query-interval <query-interval>
  query-response-interval <query-response-interval>
  quick-client-convergence
  robustness-variable <robustness-variable>
  ssm-range <startip> <maskip>
  startup-query-count <startup-query-count>
  startup-query-interval <startup-query-interval>
  version-1-router-present-timeout <version-1-router-present-timeout>
  version-2-router-present-timeout <version-2-router-present-timeout>
```

Description

This command configures the Internet Group Management Protocol (IGMP) timers and counters. IGMP establishes and manages IP multicast group membership. See RFC 3376, "Internet Group Management Protocol, version 3" for more information.

Parameter	Description
last-member-query-count	Number of group-specific queries that Mobility Conductor sends before assuming that there are no local group members. 1-65535 2
last-member-query-interval	Maximum time, in seconds, that can elapse between group-specific query messages. 1-65535 10
max-members-per-group	Configure maximum members per group. 1-65535 300
query-interval	Interval, in seconds, at which the Mobility Conductor sends host-query messages to the multicast group address 224.0.0.1 to solicit group membership information. 1-65535 125

Parameter	Description
query-response-interval	Maximum time, in 1/10th seconds, that can elapse between when the Mobility Conductor sends a host-query message and when it receives a response. This must be less than the query-interval. 1-65535 100
quick-client-convergence	Trigger IGMP reports from client during roaming.
robustness-variable	Increase this value to allow for expected packet loss on a subnetwork. 2-10 2
ssm-range	Configure the start IP address and mask IP address for source-specific multicast range.
startup-query-count	Number of queries that the Mobility Conductor sends out at start up, separated by startup-query-interval . 1-65535 2
startup-query-interval	Interval, in seconds, at which the Mobility Conductor sends general queries on start up. 1-65535 31
version-1-router-present-timeout	Timeout, in seconds, if a version 1 IGMP router is detected. 1-65535 400
version-2-router-present-timeout	Timeout, in seconds, if a version 2 IGMP router is detected. 1-65535 400

Example

The following command configures IGMP:

```
(host) [mynode] (config) #ip igmp
(host) ^[mynode] (config-submode)#query-interval 130
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ip local

```
ip local pool <pool_name> <pool_start_address> [<pool_end_address>]
```

Description

This command configures a local IP pool for Layer-2 Tunnel Protocol (L2TP). VPN clients can be assigned IP addresses from the L2TP pool.

Parameter	Description
pool <pool_name>	Name for the address pool.
<pool_start_address>	Starting IP address for the pool.
<pool_end_address>	(Optional) Ending IP address for the pool.

Example

The following command configures an L2TP pool:

```
(host) [mynode] (config) #ip local pool pool-l2tp 10.1.1.1 10.1.1.99
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ip mobile active-domain

```
ip mobile active-domain <name>
```

Description

This command configures the mobility domain that is active on Mobility Conductor. All managed devices are initially part of the “default” mobility domain. If you use the “default” mobility domain, you do not need to specify this domain as the active domain on Mobility Conductor. However, once you assign a managed device to a user-defined domain, the “default” mobility domain is no longer an active domain on the Mobility Conductor.

Parameter	Description
<name>	Name of the mobility domain.

Example

The following command assigns Mobility Conductor to a user-defined mobility domain:

```
(host) [mynode] (config) #ip mobile active-domain campus1
```

Command History

Release	Modification

ip mobile domain

```
ip mobile domain <name>
  anchor <subnet> <netmask> <1-4094> <controller-ip> description <dscr>
  description <descr>
  hat <home-agent> [description <dscr>]
  no
```

Description

This command configures the mobility domain on the managed devices. You configure the HAT on Mobility Conductor; the mobility domain information is pushed to all managed devices that are managed by the same Mobility Conductor.

HAT entries map subnetworks or VLANs and the home agents. The home agent is typically the managed device's IP address. The home agent's IP address must be routable; that is, all managed devices that belong to the same mobility domain must be able to reach the home agent's IP address.

The maximum number of mobility datapath tunnels supported is 32. A maximum of 32 hat entries can be configured if the hat entries are not VRRP IP addresses. If VRRP IP addresses are configured in the HAT table the maximum number of HAT entries supported is less than 32 as for each VRRP entry in HAT more than two datapath tunnels are considered.

The managed device looks up information in the HAT to obtain the IP address of the home agent for a mobile client. Because there can be multiple home agents on a subnetwork, the HAT can contain more than one entry for the same subnetwork.

Parameter	Description
<name>	Name of the mobility domain.
anchor	Configures the anchor managed device. The <code>no ip mobile proxy auth-sta-roam-only</code> command has to be configured for this to work. Supported only for IPv4 clients
<subnet>	VLAN subnet IP of the anchored managed device.
<netmask>	Subnet mask of the anchored managed device.
<1-4094>	VLAN ID of the anchored managed device.
<controller-ip>	The IP address of the anchored managed device.
description	Description of the anchored managed device.
description	Description of the mobility domain. The description can be a maximum of 30 characters (including spaces).

Parameter	Description
hat	Configures a home agent table (HAT) entry.
<home-agent>	The IP address of the home agent managed device that requires mobility service.
description	Description of the HAT entry. The description can be a maximum of 30 characters (including spaces).
no	Negates any configured parameter.

Example

The following command configures HAT entries:

```
(host) [mynode] (config) #ip mobile domain east_building
(host) ^[mynode] (config-submode)#hat 192.0.2.1 description "East building
entries"
(host) ^[mynode] (config-submode)#show ip mobile domain east_building

Mobility Domains:, 1 domain(s)
-----
Domain name east_building

Home Agent Table
Home Agent      Description
-----
192.0.2.1      East building entries
```

Command History

ip mobile foreign-agent

```
ip mobile foreign-agent
  lifetime <40-65534>
  max-visitors <0-5000>
  registrations {interval <100-10000> | retransmits <0-5>}
```

Description

This command configures the foreign agent for IP mobility. A foreign agent is the managed device which handles all mobile IP communication with a home agent on behalf of a roaming client.

Parameter	Description
lifetime	Requested lifetime, in seconds, as per RFC 3344, "IP Mobility Support for IPv4". 40-65534 40
max-visitors	Maximum number of active visitors. 0-5000 5000
registrations	Frequency at which re-registration messages are sent to the home agent:
interval	Retransmission interval, in milliseconds. 100-10000 1000
retransmits	Maximum number of times the foreign agent attempts mobile IP registration message exchanges before giving up. 0-5 3

Example

The following command configures the foreign agent:

```
(host) [mynode] (config) #ip mobile foreign-agent registration interval
10000
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

ip mobile home-agent

```
ip mobile home-agent
  max-bindings <0-5000>
  replay <0-300>
```

Description

This command configures the home agent for IP mobility. A home agent for a mobile client is the managed device where the client first appears when it joins the mobility domain. The home agent is the single point of contact for the client when it roams.

Parameter	Description
max-bindings	Maximum number of mobile IP bindings. This option is an additional limitation to control the maximum number of roaming users. When the limit is reached, registration requests from the foreign agent fail which causes a mobile client to set a new session on the visited managed device, which will become its home managed device. 0-5000 5000
replay	Time difference, in seconds, for time stamp-based replay protection, as described by RFC 3344, "IP Mobility Support for IPv4". 0 disables replay. 0-300 7

Example

The following command configures the home agent:

```
(host) [mynode] (config) #ip mobile home-agent replay 100
```

ip mobile proxy

```
ip mobile proxy
  auth-sta-roam-only
  block-dhcp-release
  event-threshold <1-100>
  log-trail
  no-service-timeout <30-300>
  on-association
  refresh-stale-ip
  stale-timeout <30-3600>
  stand-alone-AP
  trail-length <1-30>
  trail-timeout <120-3600>
```

Description

This command configures the proxy mobile IP module in a mobility-enabled managed device. The *proxy mobile IP module* in a mobility-enabled managed device detects when a mobile client has moved to a foreign network and determines the home agent for a roaming client. The proxy mobile IP module performs the following functions:

- erives the address of the home agent for a mobile client from the HAT using the mobile client's IP address. If there is more than one possible home agent for a mobile client in the HAT, the proxy mobile IP module uses a discovery mechanism to find the current home agent for the client.

- etects when a mobile client has moved. Client moves are detected based on ingress port and VLAN changes and mobility is triggered accordingly. For faster roaming convergence between AP (s) on the same managed device, it is recommended that you keep the **on-association** option enabled. This helps trigger mobility as soon as 802.11 association packets are received from the mobile client.

Parameter	Description
auth-sta-roam-only	Allows a client to roam only if has been authenticated. If a client has not been authenticated, no mobility service is offered if it roams to a different VLAN or managed device. enabled
block-dhcp-release	Filters out DHCP release from stations.
event-threshold	Maximum number of mobility events (events that can trigger mobility) handled per second. Mobility events above this threshold are ignored. This helps to control frequent mobility state changes when the client bounces back and forth on APs before settling down. 1-100

Parameter	Description
	25
log-trail	Enables logging at the notification level for mobile client moves. enabled
no-service-timeout	Time, in seconds, after which mobility service expires. If nothing has changed from the previous state, the client is given another bridge entry but it will have limited connectivity. 3-300 180
on-association	Enabling this option triggers mobility on station association. Mobility move detection is performed when the client associates with the managed device and not when the client sends packets. Mobility on association can speed up roaming and improve connectivity for devices that can trigger mobility if they do not send many uplink packets. Downside is security; an association is all it takes to trigger mobility. This option is applicable only if layer-2 security is enforced. It is recommended to retain the default settings as this option causes more load in the system due to exchange of extra messages between managed device in the mobility domain. disabled
refresh-stale-ip	Mobility forces station to renew its stale IP (assuming its DHCP) by deauthorizing the station.
stale-timeout	Number of seconds the mobility state is retained after the loss of connectivity. This allows authentication state and mobility information to be preserved on the home agent managed device. The default is 60 seconds but can be safely increased. Note that in many case a station state is deleted without waiting for the stale timeout; user delete from management, foreign agent to foreign agent hand-off, etc. (This is different from the no-service-timeout; no-service-timeout occurs up front while the stale-timeout begins when mobility service is provided but the connection is disrupted for some reason.) 30-3600 60
stand-alone-AP	Enables support for third party or stand-alone APs. When this is enabled, broadcast packets are not used to trigger mobility and packets from untrusted interfaces are accepted. If mobility is enabled, you must also enable stand-alone AP for the client to connect to the managed device's untrusted port. If the managed device learns wired users via the following methods, enable stand-alone AP:

Parameter	Description
	<ul style="list-style-type: none"> Third party AP connected to the managed device through the untrusted port. Clients connected to ENET1 on APs with two ethernet ports. Wired user connected directly to the managed device's untrusted port. <p>disabled</p> <p>NOTE: When IP mobility is enabled, you must also enable the stand-alone AP Support option so that a Multiplexer (MUX) server can perform properly and display all wired users who are connected to a MUX port.</p>
trail-length	<p>Specifies the maximum number of entries (client moves) stored in the user mobility trail.</p> <p>1-30 30</p>
trail-timeout	<p>Specifies the maximum interval, in seconds, an inactive mobility trail is held.</p> <p>120-3600 600</p>

Example

The following command triggers mobility on station association:

```
(host) [mynode] (config) #ip mobile proxy on-association
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ip mobile revocation

```
ip mobile revocation
  interval <100-10000>
  retransmits <0-5>
```

Description

This command configures the frequency at which registration revocation messages are sent. A home agent or foreign agent can send a registration revocation message, which revokes registration service for the mobile client. For example, when a mobile client roams from one foreign agent to another, the home agent can send a registration revocation message to the first foreign agent so that the foreign agent can free any resources held for the client.

Parameter	Description
<code>interval</code>	Retransmission interval, in milliseconds. 100-10000 1000
<code>retransmits</code>	Maximum number of times the home agent or foreign agent attempts mobile IP registration or revocation message exchanges before giving up. 0-5 3

Example

The following command configures registration revocation messages:

```
(host) [mynode] (config) #ip mobile revocation interval 2000
```

Command History

Release	Modification

ip name-server

```
ip name-server <A.B.C.D>
```

Description

This command configures servers for name and address resolution. You can configure up to six servers using separate commands. Specify one or more servers when you configure a default domain name (see [ip domain-name on page 846](#)).

Parameter	Description
<A.B.C.D>	IP address of the server.

Example

The following command configures a name server:

```
(host) [mynode] (config) #ip name-server 10.1.1.245
```

Command History

ip nat

```
ip nat pool <name> <start-ipaddr> <end-ipaddr> [<dest-ipaddr> <static>]
```

Description

This command configures a pool of IP addresses for network address translation (NAT). This command can be referenced to a session ACL rule (see [ip access-list session on page 823](#)).

Parameter	Description
<name>	Name of the NAT pool.
<start-ipaddr>	IP address that defines the beginning of the range of source NAT addresses in the pool.
<end-ipaddr>	IP address that defines the end of the range of source NAT addresses in the pool.
<dest-ipaddr>	Destination NAT IP address.
<static>	Map the NAT pool on a one-to-one basis.

Example

The following command configures a NAT pool:

```
(host) [mynode] (config) #ip nat pool 2net 2.1.1.1 2.1.1.125
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

ip nexthop-list

```
ip nexthop-list <STRING>
  ip
    dhcp vlan <id>
      priority <number>
      probe_wan_hc_ip
      <ipaddress>
    ipsec-map <map_name> [priority <number>]
  no
  preemptive-failover
```

Description

Define a next hop list for policy-based routing.

A next hop IP is the IP address of a adjacent router or device with layer-2 connectivity to the managed device. If the managed device uses policy-based routing to forwards packets to a next hop device and that device becomes unreachable, the packets matching the policy will not reach their destination. The next hop list provides redundancy for the next hop devices by forwarding the traffic to a backup next hop device in case of failures. If active next hop device on the list becomes unreachable, traffic matching a policy-based routing ACL is forwarded using the highest-priority active next hop on the list.

A maximum of 4 next hops can be added to a next hop list. Each next hop can be assigned a priority, which decides the order of selection of the next hop. If a higher priority next hop goes down, the next higher priority next hop which is active is chosen for forwarding. If all the next hops are configured with same priority, the order is determined based on the order in which they are configured. If all the next hops are down, traffic will not be passed through the regular destination based forwarding.

In a typical deployment scenario with multiple up-links, the default route only uses one of the uplink next-hops for forwarding packets. If a next hop becomes unreachable, the packets will not reach their destination. If your deployment uses policy-based routing based on a next hop list, any of the uplink next hops could be used for forwarding traffic. This requires a valid ARP entry (route-cache) in the system for all the policy-based routing next hops.

In a branch office managed device deployment, the site up-links can obtain their IP addresses and default gateway using DHCP. In such deployments, the next hop-list configuration can use the VLAN IDs of uplink VLANs. If the VLAN gets an IP address using DHCP, and the default gateway is determined by the VLAN interface, the gateway IP is used as the next hop IP address. Branch deployments may also require policy-based redirection of traffic to different VPN tunnels. The next hop list allows you to select an IPsec map to redirect traffic through IPsec tunnels.

Parameter	Description
<STRING>	Name of the next hop list.

Parameter	Description
<code>ip</code>	Next hop IP address.
<code>dhcp vlan <id></code>	VLAN ID of the VLAN used by the next hop device. If the VLAN gets an IP address using DHCP, and the default gateway is determined by the VLAN interface, the gateway IP is used as the next hop IP address.
<code>priority <number></code>	Next hop selection priority.
<code>probe_wan_hc_ip</code>	Enables next hop failover, if the uplink health check of the next hop is unreachable
<code><A.B.D.C></code>	IP address of the next hop device.
<code>ipsec-map <map_name></code>	Packets can be redirected over a VPN tunnel by specifying the IPsec map name.
<code>preemptive-failover</code>	Enable or disable preemptive failover. If preemption is enabled and a higher priority next hop becomes reachable again, packets are again forwarded to the higher priority next hop.

Example

The following command configures a list of next hops:

```
(host) [mynode] (config) #ip nexthop-list list1
(host) ^[mynode] (config-submode)#ip 10.1.1.41 priority 1
(host) ^[mynode] (config-submode)#ip 172.21.18.170 priority 2
(host) ^[mynode] (config-submode)#ip 192.18.140.20 priority 3
```

ip probe default

```
ip probe default
  burst-size <size>
  frequency <seconds>
  mode ping
  no
  retries <count>
```

Description

This command configures IP probes for the policy-based routing using a next-hop list. The health-check feature uses ping-probes to check reachability and latency from the managed device to data center through each of the managed device's WAN up-links. Latency is calculated based on the round-trip time (RTT) of ping responses. Ping settings are configured globally using the `ip probe default` command.

Parameter	Description
<code>burst-size</code> <size>	Number of probes to be sent during the probe frequency interval defined by the <code>frequency</code> parameter of this profile. 1-16 5
<code>frequency</code> <seconds>	Probe interval, in seconds. The WAN health-check feature sends the number of probes defined by the <code>burst-size</code> parameter during each frequency interval defined by this <code>frequency</code> parameter. 10-3600 10
<code>mode ping</code>	Enable this feature by issuing the <code>mode ping</code> command. Ping is the only mode currently supported by this feature.
<code>no</code>	Remove or negate any configured parameter.
<code>retries</code> <count>	Number of times the managed device attempts to resend a probe. 1-255 3

Examples

The following commands enable this feature, and reduce the default probe frequency interval and probe burst size:

```
(host) [mynode] (config) #ip probe default
(host) ^[mynode] (config-submode)#burst-size 3
(host) ^[mynode] (config-submode)#frequency 5
(host) ^[mynode] (config-submode)#mode ping
```

ip probe health-check

```
ip probe health-check
  burst-size <size>
  frequency <frequency>
  mode {ping|udp}
  jitter
  no
  retries <count>
```

Description

This command configures WAN health-check ping-probes for measuring WAN availability and latency on managed device up-links. The health-check feature uses ping-probes to check reachability and latency from the managed device to data center through each of the managed device's WAN up-links. Latency is calculated based on the delay of ping responses.

Parameter	Description
<code>burst-size</code> <size>	Number of probes to be sent during the probe frequency interval defined by the <code>frequency</code> parameter of this profile. 1-16 5
<code>frequency</code> <seconds>	Probe interval, in seconds. The WAN health-check feature sends the number of probes defined by the <code>burst-size</code> parameter during each frequency interval defined by this <code>frequency</code> parameter. 10-3600 10
<code>jitter</code>	Jitter is a variation in the delay of received packets, which can be worsened by network congestion, improper queuing and configuration errors. The WAN health-check feature measures jitter on the connection to the remote host by sending and measuring packets at fixed intervals. Jitter measurements are only available if the health-check feature is set to send UDP packets.
<code>mode</code> {ping udp}	Enable this feature by issuing the mode command and choosing the type of probe packets to be sent, ping or udp .
<code>no</code>	Remove or negate any configured parameter.
<code>retries</code> <count>	Number of times the managed device attempts to resend a probe. 1-255 3

Examples

The following commands enable this feature, and reduce the default probe frequency interval and probe burst size.

```
(host) [mynode] (config) #ip probe health-check
(host) ^[mynode] (config-submode)#burst-size 3
(host) ^[mynode] (config-submode)#frequency 5
(host) ^[mynode] (config-submode)#mode udp
(host) ^[mynode] (config-submode)#jitter
```

ip radius

```
ip radius
nas-ip {nas-vlan <nasvlan>|<A.B.C.D>}
rfc-3576-server udp-port <0-65535>
source-interface {loopback|vlan <1-4094>}
```

Description

This command configures global parameters for RADIUS servers. If the `aaa authentication-server radius` command configures a server-specific NAS IP, the server-specific IP address is used instead.

Parameter	Description
<code>nas-ip</code>	A global Network Access Server (NAS) IP address to send in RADIUS packets. This configuration supersedes the server-specific NAS IP configured with the <code>aaa authentication-server radius</code> command.
<code>nas-vlan</code>	Configure the NAS VLAN to be used as the NAS IP address.
<code>A.B.C.D</code>	Configure the NAS IP address.
<code>rfc-3576-server udp-port <0-65535></code>	Configures the UDP port to receive requests from a RADIUS server that can send user disconnect and change-of-authorization messages, as described in RFC 3576, "Dynamic Authorization Extensions to Remote Dial In User Service (RADIUS)". See the <code>aaa rfc-3576-server</code> command to configure the server. 0-65535 3799
<code>source-inter face</code>	Interface for all outgoing RADIUS packets. The IP address of the specified interface is included in the IP header of RADIUS packets. The interface can be one of the following:
<code>loopback</code>	Use the IP address of the loopback interface.
<code>vlan</code>	Use the IP address of the VLAN. 1-4094

Example

The following command configures a global NAS IP address sent in RADIUS packets:

```
(host) [mynode] (config) #ip radius nas-ip 192.168.1.245
```

Command History

Release	Modification

ip route

```
ip route <destip> <destmask> {ipsec <name> [<cost>]|null <0-0>|<nexthop> [<cost>]}
```

Description

This command configures a static route on Mobility Conductor or the managed device. Use the `ip default-gateway` command to set the default gateway to the IP address of the interface on the upstream router or switch to which you connect Mobility Conductor or the managed device.

Parameter	Description
<destip>	Enter the destination IP address prefix in dotted decimal format (A.B.C.D).
<destmask>	Enter the destination netmask in dotted decimal format (A.B.C.D).
ipsec <name>	Enter the IPsec map name to use a static IPsec route map.
null <0-0>	Enter the key word null 0 to designate a null interface.
<nexthop> [<cost>]	Enter the forwarding router address in dotted decimal format (A.B.C.D). Optionally, enter the distance metric (cost) for this route. The cost prioritizes routing to the destination. The lower the cost, the higher the priority.

Example

The following command configures a static route:

```
(host) [mynode] (config) #ip route 172.16.0.0 255.255.0.0 10.1.1.1
```

ip-flow-export-profile

```
ip-flow-export-profile
  collector-ip <collector-ip>
  enable
  flow-cache-size <flow-cache-size>
  no
  observation-domain <observation-domain>
  port <port>
  transport-protocol {tcp | udp}
  upload-all-interval <upload-all-interval>
  upload-snapshot-interval <upload-snapshot-interval>
  upload-template-interval <upload-template-interval>
  wireless-export
```

Description

This command configures the IP flow collector profile. This command should be configured under **/md**.

Parameter	Description
collector-ip <collector-ip>	Assigns a managed device as the IP Flow Collector within its node.
enable	Enables the IP Flow Collector.
flow-cache-size <flow-cache-size>	Determines the maximum number of entries a managed device can cache before the log is exported to the IP Flow Collector. 5000–25000
no	Negates the prior configuration.
observation-domain <observation-domain>	Allows the IP Flow Collector to group managed devices when receiving data sessions. Switch IP as 32 Bit number
port <port>	Assigns the port to which the exported caches are sent on the IP Flow Collector.
transport-protocol	Determines the transport protocol when a cache is exported.
tcp	Assigns TCP as the transfer protocol .
udp	Assigns UDP as the transfer protocol.
upload-all-interval <upload-all-interval>	Determines the maximum time interval allowed before a managed device must export its cache to the IP Flow Collector.

Parameter	Description
	0–30 minutes, 0 to disable
upload-snapshot-interval <upload-snapshot-interval>	Determines the maximum time interval cache for an inactive flow is exported. 0–30 minutes, 0 to disable
upload-template-interval <upload-template-interval>	Determines the maximum time interval to upload IPFIX templates. 0–30 minutes, 0 to disable 0
wireless-export	Enables wireless export. Disabled

Example

The following command configures a DHCP pool:

```
(host) [mynode] (config) #ip-flow-export-profile
(host) [mynode] (IP Flow Collector Profile) #enable
(host) [mynode] (IP Flow Collector Profile) #collector-ip 192.0.2.1
(host) [mynode] (IP Flow Collector Profile) #write memory
```

Related Commands

Command	Description
show ip-flow-export wireless-cache	Displays the cache for WLAN information.

Command History

Release	Modification
ArubaOS 8.0.1.0	The <code>wireless-export</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on the Mobility Conductor.

ipv6 cp-redirect-address

ipv6 cp-redirect-address <ip6addr> | disable

Description

This command configures a redirect address for captive portal. This command redirects wireless clients that are on different VLANs (from the managed device's IP address) to the captive portal on the managed device.

If you have the Next Generation PEFNG license installed in the managed device, modify the captive portal session ACL to permit HTTPS traffic to the destination **cp-redirect-address <ip6addr>** instead of **mswitch**. If you do not have the PEFNG license installed in the managed device, the implicit captive-portal-profile ACL is automatically modified when you issue this command.

Parameter	Description
<ip6addr>	This address should be routable from all external networks.
disable	Disables automatic DNS resolution for captive portal.

Example

The following command configures a captive portal redirect address:

```
(host) [/md] (config) #ipv6 cp-redirect-address
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

ipv6 default-gateway

```
ipv6 default-gateway mgmt <ipv6-address> <cost>
```

Description

This command configures an IPv6 default gateway.

Parameter	Description
mgmt	Specify the Management Interface.
<ipv6-address>	Specify the IPv6 address of the default gateway.
cost	Specify the distance metric to select the routing protocol that determines the way to learn the route.

Example

The following command configures an IPv6 default gateway:

```
(host) [/md] (config) #ipv6 default-gateway 2cce:205:160:100::fe 1
```

The following example displays the use of extended scope of address range:

```
(host) [/md] (config) #ipv6 default-gateway 2014::1
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

ipv6 dhcp excluded-address

```
ipv6 dhcp excluded-address <low-address> [<high-address>]
```

Description

This command configures an excluded IPv6 address range for the DHCPv6 server on the Mobility Conductor. Ensure that the statically assigned IPv6 addresses are excluded.

Parameter	Description
<low-ipaddr>	Low end of range of IPv6 addresses. For example, you can enter an IPv6 address that should not be assigned.
<high-ipaddr>	High end of the range of IPv6 addresses.

Example

The following command configures an excluded IPv6 address range:

```
(host) [/md/X.X.X.X.X] (config-dhcpv6)#ipv6 dhcp excluded-address  
2002:570:20::2 2002:570:20::25
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

ipv6 dhcp pool

```
ipv6 dhcp pool <pool-name>
  dns-server {switch-gw-ipv6 | <ipv6-address>}
  domain-name <domain>
  lease <days> <hours> <minutes> <seconds>
  network <network prefix>
  no ...
  option <code> {ip <ipv6-addr> | text <string>}
  preference <1-255>
```

Description

This command configures a DHCPv6 pool on the Mobility Conductor. A DHCPv6 pool should be created for each IPv6 subnetwork for which DHCPv6 services should be provided. DHCPv6 pools are not specifically tied to VLANs, as the DHCPv6 server exists on every VLAN. When the Mobility Conductor receives a DHCPv6 request from a client, it examines the origin of the request to determine if it should respond. If the IPv6 address of the VLAN matches a configured DHCPv6 pool, the Mobility Conductor answers the request.

Parameter	Description
dns-server	IPv6 address of the DNS server.
switch-gw-ipv6	Configure DNS server as Switch Gateway IPv6 address. Use this parameter when Redirect-DNS has to be enabled on the current pool.
<ipv6-address>	IPv6 address of the DHCP DNS server.
domain-name	Domain name to which the client belongs.
lease	The amount of time that the assigned IPv6 address is valid for the client. Specify the lease in <days> <hours> <minutes> <seconds>. The default value is 12 hours.
network	The DHCPv6 network prefix.
no	Negates any configured parameter.
option	Client-specific option code and IPv6 address or text. See RFC 3315, DHCPv6.
preference	The DHCPv6 server preference.

Example

The following command configures a DHCPv6 pool:

```
(host) [/md/X.X.X.X.X.X] (config) #ipv6 dhcp pool DHCPv6
(host) [/md/X.X.X.X.X.X] (config-submode) #dns-server 2001:470:20::2
(host) [/md/X.X.X.X.X.X] (config-submode) #domain-name test.org
(host) [/md/X.X.X.X.X.X] (config-submode) #lease 0 12 0 0
(host) [/md/X.X.X.X.X.X] (config-submode) #network 2001:470:20::/64
(host) [/md/X.X.X.X.X.X] (config-submode) #option 24 text "Domain Search
List"
(host) [/md/X.X.X.X.X.X] (config-submode) #preference 25
```

The following example displays the use of extended scope of address range, which is restricted only to DHCP pool configuration:

```
(host) [/md/X.X.X.X.X.X] (config) #ipv6 dhcp pool sparta
network 2012::/120
!
```

If the DHCP pool configuration on the managed device, that acts as a DHCP server has the address pool configured in the reserved range, then the APs get an IP address from the server. If the address pool is not in the reserved range, then the AP cannot get an IP from the server.

Command History

Release	Modification
ArubaOS 8.4.0.0	The <code>switch-gw-ipv6</code> sub-parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

ipv6 dhcp relay-option

```
ipv6 dhcp relay-option <xml_file_name>
```

Description

This command configures the DHCPv6 relay options by using XML file. The XML definition file allows you to configure DHCPv6 Option 18 (Circuit ID) and Option 37 (Remote ID) sub-type options.

You must upload the XML file to Mobility Conductor flash file system, before issuing this command.

Example

The following example configures a DHCPv6 Relay-Option:

```
(host)[mynode](config) #ipv6 dhcp relay-option my_dhcp_relay-option.xml
```

ipv6 domain-redirect

```
ipv6 domain-redirect <name> <ipv6-addr>
```

Description

This command redirects the domain to a dedicated DNS server in the IPv6 domain. This command is enabled by default. Use the **no** form of this command to disable.

Parameter	Description
<name>	Specifies the domain name to be redirected.
<ipv6-addr>	Specifies the domain server IPv6 address.

Example

The following command redirects the domain to a dedicated DNS server:

```
(host) [mynode] (config) #ipv6 domain-redirect xyzcorp.com 2001:0000::1101
```

ipv6 enable

ipv6 enable

Description

This command enables IPv6 packet processing globally. This option is disabled by default.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Available on all platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ipv6 firewall

```
ipv6 firewall
  attack-rate {ping <number>|session <number>|tcp-syn <number>}
  deny-inter-user-bridging |
  drop-ip-fragments |
  enable-per-packet-logging |
  enable-stateful-icmp |
  enforce-tcp-handshake |
  enforce-tcp-sequence |
  ext-hdr-parse-len |
  no
  prohibit-ip-spoofing |
  prohibit-rst-replay |
  session-idle-timeout <seconds>
```

Description

This command configures firewall options on the Mobility Conductor for IPv6 traffic.

Parameter	Description
attack-rate	Sets rates which, if exceeded, can indicate a denial of service attack.
ping	Number of ICMP pings per 30 seconds, which if exceeded, can indicate a denial of service attack. Recommended value is 120. 1-16384
session	Number of TCP or UDP connection requests per 30 seconds, which if exceeded, can indicate a denial of service attack. Recommended value is 960. 1-16384
tcp-syn	Number of TCP SYN messages per 30 seconds, which if exceeded, can indicate a denial of service attack. Recommended value is 960. 1-16384
deny-inter-user-bridging	Prevents the forwarding of Layer-2 traffic between wired or wireless users. You can configure user role policies that prevent Layer-3 traffic between users or networks but this does not block Layer-2 traffic. This option can be used to prevent Appletalk or IPX traffic from being forwarded. disabled
drop-ip-fragments	When enabled, all IP fragments are dropped. You should not enable this option unless instructed to do so by a customer support representative.

Parameter	Description
	disabled
enable-per-packet-logging	Enables logging of every packet if logging is enabled for the corresponding session rule. Normally, one event is logged per session. If you enable this option, each packet in the session is logged. You should not enable this option unless instructed to do so by a customer support representative, as doing so may create unnecessary overhead on the Mobility Conductor. disabled
enforce-stateful-icmp	Enables stateful ICMP processing and create sessions for ICMP errors and denies unidirectional response. disabled
enforce-tcp-handshake	Prevents data from passing between two clients until the three-way TCP handshake has been performed. This option should be disabled when you have mobile clients on the network as enabling this option will cause mobility to fail. You can enable this option if there are no mobile clients on the network. disabled
enforce-tcp-sequence	Prevents data from passing between two clients until the three-way TCP sequence numbers are exchanged.
ext-hdr-parse-len	Set the threshold value beyond which the IPv6 header will not be parsed and the packet will be dropped. 100 bytes
prohibit-ip-spoofing	Detects IP spoofing (where an intruder sends messages using the IP address of a trusted client). When this option is enabled, IP and MAC addresses are checked; possible IP spoofing attacks are logged and an SNMP trap is sent. disabled
prohibit-rst-replay	Closes a TCP connection in both directions if a TCP RST is received from either direction. You should not enable this option unless instructed to do so by a customer support representative. disabled
session-idle-timeout	Time, in seconds, that a non-TCP session can be idle before it is removed from the session table. You should not modify this option unless instructed to do so by a customer support representative. 16-300 16 seconds

Example

The following command does not allow forwarding of non-IP frames between IPv6 clients:

```
(host) [/md] (config) #ipv6 firewall deny-inter-user-bridging
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

ipv6 helper-address

```
ipv6 helper-address  
  helper-address <address>  
  source <srcaddr>
```

Description

This command configures the DHCPv6 server relay agent. .

Parameter	Description
helper-address	Configures DHCPv6 server relay agent.
source	Configure DHCPv6 relay source address if the interface has more than one IPv6 address.

Example

The following command configures a helper address:

```
(host) [00:0c:29:3c:f7:d3] (config-submode)#ipv6 helper-address 2017::2  
source 2016::2
```

ipv6 local

```
ipv6 local  
  pool <pool_name_v6> <pool_start_addressv6> <pool_end_addressv6>
```

Description

This command configures a local IPv6 pool for Layer-2 Tunnel Protocol (L2TP). VPN clients can be assigned IPv6 addresses from the L2TP pool.

Parameter	Description
pool	Name for the address pool.
<pool_start_addressv6>	Starting IPv6 address for the pool.
<pool_end_addressv6>	(Optional) Ending IPv6 address for the pool.

Example

The following command configures a local IPv6 pool:

```
(host) [mynode] (config) #ipv6 local pool  
2001:0000:0eab:DEAD:0000:00AO:ABCD:004E  
2002:0000:0eab:DEAD:0000:00AO:ABCD:004E
```

ipv6 name-server

```
ipv6 name-server  
X:X:X:X::X
```

Description

This command configures the IPv6 address of the domain name server.

Parameter	Description
X:X:X:X::X	Domain server IPv6 address (maximum of 6).

Example

The following command adds IPv6 name server (DNS server):

```
(host) [mynode] (config) #ipv6 name-server 2020::abcd:abcd
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The domain server IPv6 address was added.

ipv6 neighbor

ipv6 neighbor <ipv6addr> vlan <vlan#> <mac>

Description

This command configures an IPv6 static neighbor on a VLAN interface.

Parameter	Description
<ipv6addr>	Specify the IPv6 address of the neighbor entry.
vlan <vlan#>	Specify the VLAN ID.
<mac>	Specify the 48-bit hardware address of the neighbor entry.

Example

The following command configures an IPv6 static neighbor on VLAN 1:

```
(host) [/md/X.X.X.X.X] (config) #ipv6 neighbor 2cce:205:160:100::fe vlan 1  
00:0b:86:61:13:28
```

ipv6 nexthop-list

```
ipv6 nexthop-list <STRING>
  ipsec6-map <map_name> [priority <number>]
  ipv6 {<X:X:X:X:X:X:X> [priority <number>]}
  no
  preemptive-failover
```

Description

This command defines a next-hop list for IPv6 address in policy-based routing.

A next-hop IP is the IPv6 address of an adjacent router or device with layer-2 connectivity to the managed device. If the managed device uses policy-based routing to forwards packets to a next-hop device and that device becomes unreachable, the packets matching the policy will not reach their destination. The next-hop list provides redundancy for the next-hop devices by forwarding the traffic to a backup next-hop device in case of failures. If active next-hop device on the list becomes unreachable, traffic matching a policy-based routing ACL is forwarded using the highest-priority active next-hop on the list. You can verify the reachability by using `show ip health-check` command. All the next-hop IPv6 addresses are added to the health-check if the next-hop is used by a route ACL. The datapath uses only the next-hop devices that are reachable.

A maximum of 16 next-hops can be added to a next-hop list. Each next-hop can be assigned a priority, which decides the order of selection of the next-hop. If a higher priority next-hop goes down, the next higher priority next-hop which is active is chosen for forwarding. If all the next-hops are configured with same priority, a round-robin order is used. If all the next-hops are down, traffic is dropped and regular destination based forwarding happens when IPv6 forward rule is configured explicitly in ACL for PBR.

In a typical deployment scenario with multiple up-links, the default route only uses one of the uplink next-hops for forwarding packets. If a next-hop becomes unreachable, the packets will not reach their destination. If your deployment uses policy-based routing based on a next-hop list, any of the uplink next-hops could be used for forwarding traffic. This requires a valid ARP entry (route-cache) in the system for all the policy-based routing next-hops.

Branch deployments may also require policy-based redirection of traffic to different site-to-site tunnels. The next-hop list allows you to select an IPsec map to redirect traffic through IPsec tunnels.

A maximum of 32 next-hop lists (IPv4 and IPv6) is allowed.

Parameter	Description
<STRING>	Name of the next-hop list. NOTE: You cannot use the same name for both IPv4 and IPv6 next-hop lists.

Parameter	Description
<code>ipsec6-map <map_name></code>	Packets can be redirected over a site-to-site tunnel by specifying the IPsec map name. NOTE: Only site-to-site VPN is currently supported for IPv6. Hence, the IPsec map is limited to the site-to-site map.
<code>[priority <number>]</code>	(Optional) Use this parameter to assign priority to next-hop. 1-255 128
<code>ipv6 <X:X:X:X:X:X:X></code>	IPv6 address of the next-hop device.
<code>[priority <number>]</code>	(Optional) Use this parameter to assign priority to next-hop. 1-255 128
<code>no</code>	Negates any configured parameter.
<code>preemptive-failover</code>	Enable or disable preemptive failover. If preemption is enabled and a higher priority next-hop becomes reachable again, packets are again forwarded to the higher priority next-hop. NOTE: This option is enabled by default.

Example

The following command configures a list of next-hops:

```
(host) [mynode] (config) #ipv6 nexthop-list new
(host) ^[mynode] (config-submode)#ipv6 2005::1 priority 1
(host) ^[mynode] (config-submode)#ipv6 2002::2 priority 2
(host) ^[mynode] (config-submode)#ipv6 2008::4 priority 3
```

Related Commands

Command	Description

show ip health-check	Display the health-check status of the uplink interfaces of a branch office managed device.

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Available in the base operating system.	Config mode on Mobility Conductor.

ipv6 mld

```
ipv6 mld
  max-members-per-group <val>
  no
  query-interval <query-interval>
  query-response-interval <query-response-interval>
  robustness-variable <robustness-variable>
  ssm-range <startip> <maskip>
```

Description

This command configures the IPv6 MLD (Multi-listener discovery) parameters. You can modify the default values of the MLD parameters for IPv6 MLD snooping. You must enable IPv6 MLD snooping for these values to take effect. For more information on enabling IPv6 MLD snooping, see [interface vlan on page 776](#).

Parameter	Description
max-members-per-group	Configure maximum members per group (1-65535). The default value is 300.
query-interval	Specify the time interval in seconds (1-65535) between general queries. The default value is 125 seconds. By varying this value, you can tune the number of MLD messages on the link; larger values cause MLD queries to be sent less often.
query-response-interval	Specify the maximum response delay in deciseconds (1/10 seconds) that can be inserted into the periodic general queries. The default value is 100 deciseconds. By varying this value, you can tune the burstiness of MLD messages on the link; larger values make the traffic less bursty, as node responses are spread out over a larger interval. The number of seconds represented by this value must be less than the query interval.
robustness-variable	Specify a value between 2 to 10. The default value is 2. The robustness variable allows you to tune for the expected packet loss on a link. If a link is expected to be lossy, you can increase this value. You must not configure the robustness variable as 0 or 1.
ssm-range	Specify the source specific multicast IPv6 range. This variable allows you to configure a valid multicast IPv6 address range for which SSM semantics needs to be applied. The default IPv6 SSM address range is FF3X::4000:1 – FF3X::FFFF:FFFF.

Example

The following command configures the query interval of 200 seconds for IPv6 MLD snooping:

```
(host) [/md/X.X.X.X.X.X] (config) #ipv6 mld
(host) [/md/X.X.X.X.X.X] (config-mln) # query-interval 200
```

Command History

Release	Modification
ArubaOS 8.2.0.0	The <code>max-members-per-group</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

ipv6 proxy-ra

```
ipv6 proxy-ra  
  interval <value>
```

Description

This command configures an interval for proxy RA.

Parameter	Description
interval	Configures the proxy RA interval (180-1800 sec). This overrides interface RA interval value if it is lesser.

Example

The following command enables proxy RA:

```
(host) [md] (config) #ipv6 proxy-ra  
IPv6 RA proxy already enabled.
```

The following command configures a global NAS IPv6 address sent in RADIUS packets:

```
(host) [md] (config) #ipv6 proxy-ra interval 200
```

Command History

Release	Modification
ArubaOS 8.1.0.0	The <code>proxy-ra</code> parameter was modified to enable proxy RA.
ArubaOS 8.0.0.0	Command introduced.

ipv6 radius

```
ipv6 radius
  nas-ip6 { nas-vlan <nasvlan>|<ipv6-addr>}
  source-interface {loopback|vlan <vlan> <ip6addr>}
```

Description

This command configures global parameters for configured IPv6 RADIUS servers. If the `aaa authentication-server radius` command configures a server-specific NAS IPv6 address, the server-specific IPv6 address is used instead.

Parameter	Description
<code>nas-ip6</code>	A global NAS IPv6 address to send in RADIUS packets. This configuration supercedes the server-specific NAS IPv6 configured with the <code>aaa authentication-server radius</code> command.
<code>nas-vlan <nasvlan></code>	The NAS VLAN to be used as NAS IP.
<code>ipv6-addr</code>	The NAS IPv6 address.
<code>source-interface</code>	Interface for all outgoing RADIUS packets. The IPv6 address of the specified interface is included in the IP header of RADIUS packets. The interface can be one of the following:
<code>loopback</code>	The loopback interface.
<code>vlan</code>	The specified VLAN.

Example

The following command configures a global NAS IPv6 address sent in RADIUS packets:

```
(host) [md] (config) #ipv6 radius nas-ip6 2001:470:20::2
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

ipv6 route

```
ipv6 route {X:X:X:X::X/<0-128>}|ipv6-next-hop|null|vlan[vlanid]|link-local-next-hop}|cost
```

Description

This command configures static IPv6 routes on the managed device.

Parameter	Description
X:X:X:X::X/<0-128>	Specify the IPv6 address and the prefix length of the destination.
<ipv6-next-hop>	Specify the next-hop IPv6 address or null 0 to terminate or discard the packets. Listed below are the following options: <ul style="list-style-type: none">▪ X:X:X:X::X-IPv6 address of next-hop. The address should only be a Global IPv6 address.▪ null-Null interface▪ vlan-Vlan for link local for next-hop▪ <vlanid>-Vlan-id for link local next-hop▪ X:X:X:X::X-IPv6 link local address of next-hop
<cost>	Specify the distance metric to select the routing protocol that determines the way to learn the route.

Example

The following command configures a static IPv6 route on the managed device:

```
(host) [/md/X.X.X.X.X.X] (config) #ipv6 route 2cce:205:160:100::/<64>
2001:205:160:100::ff 1
(host) [/md/X.X.X.X.X.X] (config) #ipv6 route 2000:eab::/64 vlan 1
fe80::1a:1e00:a00:9f0
The following example displays the use of extended scope of address range:
(host) [/md/X.X.X.X.X.X] (config) #ipv6 route 2002::/64 2004::2
```

Command History

ipv6 tacacs

```
source-interface {loopback|vlan <1-4094> [<ip6addr>]}
```

Description

This command configures parameters for configured IPv6 TACACS servers.

Parameter	Description
source-interface	Select source address of outgoing TACACS requests to the server.
loopback	Use the IPv6 address of the loopback interface.
vlan <1-4094>	Select VLAN of outgoing TACACS requests to the server. 1-4094

Example

The following command configures a VLAN IPv6 address sent in TACACS packets:

```
(host) [mynode] (config) # ipv6 tacacs source-interface vlan 25 192.168.2.55
```

Command History

ip-reputation deny [inbound|outbound]

Description

This command denies connections matching malicious IP addresses.

Parameter	Description
inbound	Denies connections originated from outside.
outbound	Denies connections originated by managed device.

Example

The following command denies connections originated from outside:

```
(host) [mynode] (config) #ip-reputation deny inbound
```

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

kernel coredump

[no] kernel coredump

Use this command under the supervision of Aruba Global Technical Support.

Description

This command enables the controller to capture the snapshot of the working memory of the control plane when the control plane has terminated abnormally. An additional flash memory available check is imposed on core dump. If less than 100 MB of space is left on the flash, the extra core dump chunks get discarded. After issuing this command, you may run the `write memory` command to save the configuration. This will enable the kernel core dumps across reboots.

Parameter	Description
coredump	Enable kernel core dump on the controller. Disabled

Example

The following example enables kernel core dump on the controller:

```
(host) (config) #kernel coredump
```

Use the following command to save the configuration change using the CLI:

```
(host) (config) #write memory
```

Use the following command to view the kernel core dump status using the CLI:

```
(host) (config) #show running-config | include kernel
Building Configuration...
kernel coredump
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

kernel printk

kernel printk

Description

This command enables the kernel printk.

Parameter	Description
printk	Enable kernel printk.

Example

The following example enables kernel core dump on the controller:

```
(host) (config) #kernel printk
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

lb-group

```
<name>  
  gre-standby  
  hold-time <number>  
  no {gre-standby|hold-time|preemption|primary|randomize-time|secondary}  
  preemption  
  primary  
  randomize-time <number>  
  secondary
```

Description

This command allows you to manage and configure the load balancing group.

Parameter	Description
name	Name of load balancing group
gre-standby	Enable GRE standby
hold-time <number>	Hold time after which failover occurs
no	Disable load balancing group features
preemption	Enable preemptive failover
primary	Configure primary map
randomize-time <number>	Random time after hold-time when failover occurs
secondary	Configure secondary map

lc-cluster group-profile

The `active-client-rebalance-threshold`, `standby-client-rebalance-threshold`, and `unbalance-threshold` parameters are not supported from ArubaOS 8.11.0.0 or later versions.

```
lc-cluster group-profile <profile>
  active-ap-lb
  active-ap-rebalance-ap-count <active-ap-rebalance-ap-count>
  active-ap-rebalance-threshold-percentage <active-ap-rebalance-threshold-
percentage>
  active-ap-rebalance-timer <active-ap-rebalance-timer>
  active-ap-unbalance-threshold-percentage <active-ap-unbalance-threshold-
percentage>
  active-client-rebalance-threshold
  clone <source>
  controller <ip> [priority <prio>] [mcast-vlan <mcast_vlan>] [vrrp-ip <vrrp_ip>
vrrp-vlan <vrrp_vlan> group <group number>]
  controller-v6 <ipv6>
  heartbeat-threshold <heartbeat-threshold>
  redundancy
  rapcluster
  standby-client-rebalance-threshold <standby-client-rebalance-threshold>
  unbalance-threshold <unbalance-threshold>
  vrrp-id <starting id>
```

Description

This command is used to configure the cluster group profile in the Mobility Conductor.

Parameter	Description
<profile>	Enter the cluster profile name you want to create.
active-ap-lb	Enable load balancing of APs by load sharing active AACs among cluster members.

Parameter	Description
active-ap-rebalance-ap-count <active-ap-rebalance-ap-count>	Specify the number of APs when active AP rebalance is initiated.
active-ap-rebalance-threshold-percentage <active-ap-rebalance-threshold-percentage>	Redistribute active AP load when active load on any cluster is beyond this configured percentage.
active-ap-rebalance-timer <active-ap-rebalance-timer>	Time, in minutes, to initiate the active AP rebalancing operation.
active-ap-unbalance-threshold-percentage <active-ap-unbalance-threshold-percentage>	Redistribute active AP load when the controller reaches the rebalance threshold and the difference between the maximum and minimum load on the controller is more than this threshold percentage.
active-client-rebalance-threshold	<p>Redistribute active client load when active load on any cluster node is beyond this configured percentage.</p> <p>NOTE: This parameter is not supported</p>

Parameter	Description
	from ArubaOS 8.11.0.0 or later versions.
clone <source>	Copy data from another controller cluster profile.
controller <ip>	Managed device to be made part of this cluster. The IPv4 Address is the value of the controller-ip
priority <prio>	Defines the priority level for the managed devices
mcast-vlan <mcast_vlan>	Enter the multicast vlan
vrrp-ip <vrrp_ip>	Configure the VIP address that will be owned by the elected VRRP master.
vrrp-vlan <vrrp_vlan>	Specifies the VLAN ID of the VLAN on which VRRP will run.
group <group_id>	The value of the parameter is an integer and the range is 1-12. The value 0 is the unset value if you do not want to group the managed devices.

Parameter	Description
<pre>controller-v6 <ipv6></pre>	<p>controller to be made part of this cluster. The IPv6 address is the value of the controller-ip.</p>
<pre>group <group_id></pre>	<p>The value of the parameter is an integer and the range is 1-12. The value 0 is the unset value if you do not want to group the managed devices.</p>
<pre>mcast-vlan <mcast_vlan></pre>	<p>Enter the multicast VLAN to be used for forwarding multicast traffic to upstream router.</p>
<pre>priority <prio></pre>	<p>Define the priority level for the managed devices. The value of this parameter is in the range of 1-255. The default value is 128.</p>
<pre>vrrp-ip-v6 <vrrp_ip_v6></pre>	<p>Configure the IPv6 address that is owned by the elected VRRP master.</p>

Parameter	Description
heartbeat-threshold	Heartbeat threshold is the time in ms that the cluster will wait before declaring a peer cluster node as dead. By default, the value is 900 ms.
redundancy	Enable load sharing redundancy among cluster members.
rapcluster	Enables the cluster behind NAT for Remote APs.
standby-client-rebalance-threshold	<p>Redistribute standby client load when total load on any cluster node is beyond this configured percentage.</p> <p>NOTE: This parameter is not supported from ArubaOS 8.11.0.0 or later versions.</p>
unbalance-threshold	Indicates the minimum difference in load percentage between max loaded cluster node and min loaded cluster node to let load balancing algorithm kick in.

Parameter	Description
	<p>NOTE: This parameter is not supported from ArubaOS 8.11.0.0 or later versions.</p>
<pre>vrrp-id <starting id></pre>	<p>This is an optional parameter which specifies the starting VRRP ID for cluster members. If this is not configured, system automatically configures VRRP groups within the range of 220-225.</p>
<pre>vrrp-passphrase <vrrp passphrase string></pre>	<p>This is an optional password of up to 8 characters that can authenticate VRRP peers in their advertisements. If this is not configured, there is no authentication password.</p>

Example

The following command adds the managed devices to a group profile:

```
(host) [md] (config)lc-cluster group-profile cluster6
(host) [md] (Classic Controller Cluster Profile "cluster6") controller
192.168.28.22 priority 128 mcast-vlan 0 vrrp-ip 0.0.0.0 vrrp-vlan 0 group 1
(host) [md] (Classic Controller Cluster Profile "cluster6") controller
192.168.28.23 priority 128 mcast-vlan 0 vrrp-ip 0.0.0.0 vrrp-vlan 0 group 1
```

```
(host) [md] (Classic Controller Cluster Profile "cluster6") controller
192.168.28.24 priority 128 mcast-vlan 0 vrrp-ip 0.0.0.0 vrrp-vlan 0 group 2
(host) [md] (Classic Controller Cluster Profile "cluster6") controller
192.168.28.26 priority 128 mcast-vlan 0 vrrp-ip 0.0.0.0 vrrp-vlan 0 group 2
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The following parameters were removed: <ul style="list-style-type: none"> ■ active-client-rebalance-threshold ■ standby-client-rebalance-threshold <standby-client-rebalance-threshold> ■ unbalance-threshold <unbalance-threshold>
ArubaOS 8.7.0.0	The default value of the heartbeat-threshold parameter was changed to 900 ms.
ArubaOS 8.5.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ vrrp-id <starting id> ■ vrrp-passphrase <vrrp passphrase string>
ArubaOS 8.4.0.0	The rapcluster parameter was added.
ArubaOS 8.2.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ active-ap-lb ■ active-ap-rebalance-ap-count ■ active-ap-rebalance-threshold-percentage ■ active-ap-rebalance-timer ■ active-ap-unbalance-threshold-percentage ■ controller-v6 ■ redundancy

Ic-cluster initiate initiate Upgrade

```
lc-cluster initiate initiate
  upgrade
    version <img_version>
      fileserver
      max-downloads
      partition <partition_id>
```

Description

This command is used to trigger the cluster upgrade in the Mobility Conductor:

Parameter	Description
upgrade	Upgrade using information in configured upgrade-profile
version <version_string>	Target image version, for example, 8.1.0.0_XXXXX
fileserver {ftp http scp tftp}	Specify file server details.
max-downloads <ap_preload_batch_size>	Maximum number of simultaneous APs doing image preload. The default is 100 per AAC.
partition <partition_id>	The partition on the managed device to which the new image is to be copied, valid values are 0 or 1 and this is optional. If the partition is not specified, it will automatically pick the alternate boot partition.

Example

```
(host) [mm] [cluster1] #lc-cluster <cluster_name> initiate upgrade version
<img_version> partition <partition_id>
```

cluster_name: The configured cluster profile name, the managed devices and APs associated to the cluster that needs to be upgraded.

Command History

Ic-cluster initiate schedule upgrade

```
lc-cluster initiate schedule upgrade
  version <version_string>
    <year> <month> <day> <hh> <mm> <ss>
    max-downloads <ap_preload_batch_size>
    partition <partition_id>
```

Description

This command is used to schedule a cluster upgrade.

Parameter	Description
version	The version to which the cluster will get upgraded to.
year	Year of the upgrade
month	Month of the upgrade
day	Day of the upgrade
hh	Hour of the upgrade
mm	Minutes of the upgrade
ss	Seconds of the upgrade
max-downloads <ap_preload_batch_size>	Maximum number of simultaneous APs doing image preload. The default is 100 per AAC.
partition <partition_id>	The partition on the managed device to which the new image is to be copied, valid values are 0 or 1 and this is optional. If the partition is not specified, it will automatically pick the alternate boot partition.

Example

The following command schedules a cluster upgrade:

```
(host) [mm] (config) #lc-cluster v4 schedule upgrade version 8.4.0.0-
sangiovese_73823 2018 04 10 00 00 00
```

lc-cluster initiate re-schedule upgrade
  version <version_string>
    <year> <month> <day> <hh> <mm> <ss>
    max-downloads
    partition <partition_id>
```

Description

This command is used to reschedule a scheduled cluster upgrade.

To reschedule a cluster upgrade, the upgrade must already be scheduled.

Parameter	Description
version <version_string>	The version to which the cluster will get upgraded to
year	Year of the upgrade
month	Month of the upgrade
day	Day of the upgrade
hh	Hour of the upgrade
mm	Minutes of the upgrade
ss	Seconds of the upgrade
max-downloads <ap_preload_batch_size>	Maximum number of simultaneous APs doing image preload. The default is 100 per AAC.
partition <partition_id>	The partition on the managed device to which the new image is to be copied, valid values are 0 or 1 and this is optional. If the partition is not specified, it will automatically pick the alternate boot partition.

lacp group

```
lacp group <group_number> mode {active | passive}
```

Description

This command allows you to enable LACP and configure LACP on the interface. LACP is disabled by default and if the group number assigned contains static port members, the command is rejected.

Parameter	Description
<group_number>	Enter the LAG number. Range: 0-7
mode {active passive}	Enter the keyword mode followed by either the keyword active or passive . <ul style="list-style-type: none">Active mode—the interface is in active negotiating state. LACP runs on any link that is configured to be in the active state. The port in an active mode also automatically initiates negotiations with other ports by initiating LACP packets.Passive mode—the interface is <i>not</i> in an active negotiating state. LACP runs on any link that is configured in a passive state. The port in a passive mode responds to negotiations requests from other ports that are in an active state. Ports in passive state respond to LACP packets.

lc-rap-pool-v6

lc-rap-pool-v6 <pool_name>

Description

This command is used to configure the Remote AP inner IPv6 pool for cluster deployment.

Parameter	Description
pool_name	Specify the name of the local IPv6 pool.
pool_start_address	Configure the start IPv6 address of the local pool.
pool_end_address	Configure the end IPv6 address of the local pool. NOTE: The maximum allowed size of the IPv6 pool is 64516.

Example

The following command assigns inner IPv6 pool to Remote APs to establish tunnel in a cluster deployment:

```
(host) [mynode] (config) #lc-rap-pool-v6 v6pool 2011::3 2011::10
```

Command History

lcd-menu

lcd-menu

```
[no] disable menu [maintenance [factory-default| media-eject| qui-quick-setup |  
media-eject | system-halt | system-reboot | upgrade-image [partition0 |  
partition1]| upload-config]]
```

Description

This command allows you to enable or disable the LCD menu either completely or for specific operations. You can use this command to disable executing the maintenance operations using the LCD menu. You can use the no form of these commands to enable the specific LCD menu.

Parameter	Description
lcd-menu	Enters the LCD menu configuration mode.
no	Delete the specified LCD menu option.
disable	Disables (or enables) the complete LCD menu.
maintenance	Disables (or enables) the maintenance LCD menu. Enabled
factory-default	Disables (or enables) the return to factory default option in the LCD menu. Enabled
media-eject	Disables (or enables) the media eject option in the LCD menu. Enabled
system-halt	Disables (or enables) the system halt option in the LCD menu. Enabled
system-reboot	Disables (or enables) the system reboot in the LCD menu. Enabled
upgrade-image	Disables (or enables) the upgrade image option in the LCD menu. Enabled
partition 0 partition 1	Disables (or enables) image upgrade on the specified partition (0 or 1). Enabled
upload-config	Disables (or enables) the upload config option in the LCD menu. Enabled

Example

The following example enables system halt and system reboot options:

```
(host) [mynode] (config) #lcd-menu
(host) [mynode] (lcd-menu) #no disable menu maintenance system-halt
(host) [mynode] (lcd-menu) #no disable menu maintenance system-reboot
```

The following example disables the LCD menu completely:

```
(host) [mynode] (config) #lcd-menu
(host) [mynode] (lcd-menu) #disable menu
```

The following example disables executing the specified maintenance operation using the LCD menu:

```
(host) [mynode] (config) #lcd-menu
(host) [mynode] (lcd-menu) #disable menu maintenance ?
factory-default          Disable factory default menu
gui-quick-setup          Disable quick setup menu on LCD
media-eject              Disable media eject menu on LCD
system-halt              Disable system halt menu on LCD
system-reboot            Disable system reboot menu on LCD
upgrade-image            Disable image upgrade menu on LCD
upload-config            Disable config upload menu on LCD
(host) (lcd-menu) #disable menu maintenance upgrade-image ?
partition0               Disable image upgrade on partition 0
partition1               Disable image upgrade on partition 1
```

You can use the following show command to display the current LCD settings:

```
(host) [mynode]#show lcd-menu
lcd-menu
-----
Menu                               Value

license

```
license
  add <key>
  asp
  del <key>
  export <filename>
  import <filename>
  remote remote-ip-addr <ip-addr> add <key>
  report <filename>}
  server-ip <ip-addr> <ipv6-addr>
```

Description

This command allows you to install, delete, and manage software licenses on Mobility Conductor. ArubaOS supports a centralized licensing architecture, which allows a group of managed devices to share a pool of licenses. A primary and backup Mobility Conductor can share a single set of licenses, eliminating the need for a redundant license set on the backup server. Managed devices maintain information sent from the Mobility Conductor, even if the managed device and the Mobility Conductor can no longer communicate.

A Mobility Conductor uses licensing pools to distribute licenses to a large number of managed devices across geographic locations. By default, all managed devices associated to a Mobility Conductor share a single global pool of all the sharable licenses added to that Mobility Conductor. However, ArubaOS also allows you to create additional licensing pools at a configuration node, allowing a groups of managed devices at or below that configuration level to share licenses among themselves, but not with other groups. For information on creating license pools using the Mobility Conductor CLI, see [license-pool-profile](#).

New licenses and license pools can only be added through the Mobility Conductor WebUI. Licenses cannot be added directly to a managed devices. If a controller had previously installed sharable licenses before it was added to a Mobility Conductor as a managed devices, those licenses are no longer usable on that device. Those license keys must be regenerated and assigned to the **managed device** or licensing pool using the Mobility Conductor WebUI.

For complete information on the centralized licensing feature, refer to the *ArubaMobility ConductorLicensing Guide*.

Parameter	Description
add <key>	Installs the software license key in Mobility Conductor. The key is normally sent to you via email.
asp	Install Aruba Support Portal license This parameter is available in enable mode.
allocate-lic	Allocate licenses.

Parameter	Description
<code>get-allocated-lic</code>	Retrieves preallocated license keys from Aruba Support Portal.
<code>get-capacity-lic</code>	Get 9240 capacity license from Aruba Support Portal.
<code>get-md-pefv-lic</code>	Get MD PEFV license from Aruba Support Portal.
<code>register-order</code>	Register license order with Aruba Support Portal.
<code>export</code>	Exports the license database on Mobility Conductor to the specified file in flash.
<code>import</code>	Replaces the license database on Mobility Conductor with the specified file in flash. The system serial numbers referenced in the imported file must match the numbers on the Mobility Conductor.
<code>remote remote-ip-addr <ip-addr> add <key></code>	Use this command to associate a non-sharable license installed on the Mobility Conductor with the managed device for which that license key was generated. The <code><ip-addr></code> parameter is the IP address of the managed device, and <code><key></code> is the license key for the non-sharable license.
<code>report</code>	Saves a license report to the specified file in flash.
<code>server-ip <ip-addr> <ipv6-addr></code>	Enter the IPv4 or IPv6 address of the licensing server on a standalone controller or a Mobility Conductor to configure that controller as a licensing client. This command must be configured from the Mobility Conductor configuration node. NOTE: If there is an IPv4 address already configured on the controller, you must remove the IPv4 address before configuring the IPv6 address, and vice versa. If only IPv4 address is configured on the controller, it can only configure IPv4 license server IP address, and not IPv6 license server IP address.

Examples

From any configuration node , issue the command `license add <key>`.

```
(host)[mynode] #license add lnZSpC2vkLM1Jw8KVYdgj2
```

  webcc-licenses {eval key <key> <num>}|{subscript key <key> <num>}}
```

Description

Use this command to create a local licensing pool and allocate licenses for that licensing pool. All managed devices associated to the same Mobility Conductor can share a pool of licenses, comprised of all the sharable licenses added to the Mobility Conductor. However, ArubaOS also allows you to create individual licensing pools at a configuration node, allowing managed devices below that node to share licenses amongst themselves but not with other managed devices.

You must use the **license add** command to add license keys to the Mobility Conductor before you can allocate sharable licenses to a license pool, or associate a non-sharable license with an individual managed device.

For complete information on the centralized licensing feature, refer to the *Aruba Mobility Conductor Licensing Guide*.

Parameter	Description
<profile>	<p>The name of the profile for which you are creating a local license pool, for example, Northwest. The profile name is limited to 63 characters.</p> <p>NOTE: In ArubaOS 8.0.x releases, the licensing pool profile name was required to be the license pool configuration path. Starting in ArubaOS 8.1, the <code>license-pool-path</code> parameter is introduced to configure the license pool path, and the profile name can be any string of 63 characters or less.</p>

Parameter	Description
acr-licenses	Add ArubaOS Advanced Cryptography (ACR) licenses to the selected pool. A license is required for each active client termination using Suite-B algorithms or protocols. Use the optional <code>eval key <key></code> parameters to specify an evaluation license key.
ap-licenses	Add AP licenses to the selected pool.
clone	Copy licenses from another license pool profile.
license-pool-path <license-pool-path>	Starting in ArubaOS 8.1.0.0, use this parameter to specify a license pool path, up to 255 characters, for example, /USA/northwest. NOTE: If you upgrade a legacy ArubaOS deployment to ArubaOS 8.1 or later, the license-pool-path parameter is automatically derived from the license-pool-profile <profile> name.
mc-va-licenses-eg mc-va-licenses-il mc-va-licenses-jp mc-va-licenses-rw mc-va-licenses-us	Add the following different MC-VA-XX license types enable APs to support regional channels for the following countries: <ol style="list-style-type: none"> 1. MC-VA-US: United states 2. MC-VA-JP: Japan 3. MC-VA-IL: Israel 4. MC-VA-EG: Egypt 5. MC-VA-RW: Rest of the world (all other countries)
mm-licenses	Add Mobility Conductor licenses to the selected pool.
pefng-licenses	Add PEF licenses to the selected pool to support PEF features, such as intelligent application identification, policy-based traffic management and controls, or stateful user firewalls.
rfp-licenses	Add RF Protect licenses to the selected pool, to support features such as spectrum analysis and WIP.
via-licenses	VIA licenses support VIA or 3rd party VPN client . VIA licenses are not consumed for site-to-site VPNs. If a managed device or standalone controller has a PEFV license, that device will not consume VIA licenses from a licensing pool, as a single PEFV license supports all VIA and 3rd party VPN clients, up to the full user capacity for that device.
webcc-licenses	Add WebCC licenses to the selected pool. The WebCC license is a subscription-based, per-AP license.
[eval key <key>]	Use the optional <code>eval key <key></code> parameters to add the specified number of licenses for an evaluation license key.
<num>	Number of licenses supported by the license key.

Examples

```
(host)[mm] (config) #license-pool-profile Southwest
(host) ^[mm] (License pool profile "Southwest") #license-pool-path
/USA/southwest
(host) ^[mm] (License pool profile "Southwest") #ap-licenses 64
(host) ^[mm] (License pool profile "Southwest") #pefng-licenses 64
(host) ^[mm] (License pool profile "Southwest") #rfp-licenses 64
```

license-pool-profile-root

```
license-pool-profile-root
  acr-license-enable
  no
  pefng-licenses-enable
  rfp-license-enable
  webcc-license-enable
```

Description

Use this command to enable shared license features within the global licensing pool. All managed devices associated to the same Mobility Conductor can share a pool of licenses, comprised of all the sharable licenses added to the Mobility Conductor. Use this command to enable the functionality for a shared license functionality within these license pools.

Only AP licenses and VIA license are enabled by default when those licenses are added to Mobility Conductor, all other licenses must be manually enabled.

For complete information on the centralized licensing feature, refer to the *Aruba Mobility Conductor Licensing Guide*.

Parameter	Description
acr-license-enable	Enable ArubaOS Advanced Cryptography features. A license is required for each active client termination using Suite-B algorithms or protocols.
no ...	Include the no parameter before any license type to remove that configuration setting and disable licensing features for that license type.
pefng-licenses-enable	Enable PEF features, such as intelligent application identification, policy-based traffic management and controls, or stateful user firewalls.
rfp-license-enable	Enable RF Protect features, such as spectrum analysis and WIP.
webcc-license-enable	The Web Content Classification license is a subscription-based, per-AP license. Issue the <code>webcc-license-enable</code> command to enable web content classification features for the duration of the subscription period (up to 10 years per license)

Examples

From the SC configuration, issue the command `license-pool-profile-root acr-license-enable`.

```
(host) [MM] (config) #license-pool-profile-root
(host) [MM] (License root(/) pool profile) #acr-license-enable
```

local-custom-cert

```
local-custom-cert local-mac <lmac> ca-cert <ca> server-cert <cert> load-balance  
suite-b <gcm-128 | gcm-256>
```

Description

This command configures the user-installed certificate for secure communication between a managed device and a Mobility Conductor.

Use this command on a Mobility Conductor to configure the custom certificate for communication with a managed device. On the managed device, use the **masterip** command to configure the IP address and certificates for the Mobility Conductor. If your Mobility Conductor and managed devices use certificates for authentication, the IPsec tunnel will be created using IKEv2. When a managed device communicates with the Mobility Conductor to set up IPsec tunnels, the uplink vlan tag configured via the [uplink](#) command will be sent along in the vendor-id payload during IKE negotiation. This will uniquely bind the tunnel from a particular uplink on the managed device to a corresponding map on Mobility Conductor.

Parameter	Description
<lmac>	MAC address of the managed device with a local custom certificate.
ca-cert <ca>	User-defined name of a trusted CA certificate installed on the managed device. Use the <code>show crypto-local pki TrustedCA</code> command to display the CA certificates that have been imported into the managed device.
server-cert <cert>	User-defined name of a server certificate installed on the managed device. Use the <code>show crypto-local pki ServerCert</code> command to display the server certificates that have been imported into the managed device.
suite-b	If you configure your Mobility Conductor to use IKEv2 and custom-installed certificates, you can optionally use Suite-B cryptographic algorithms for IPsec encryption. Specify one of the following options: <ul style="list-style-type: none">▪ gcm-128 Use 128-bit AES-GCM Suite-B encryption▪ gcm-256 Use 256-bit AES-GCM Suite-B encryption

Example

The following command configures the managed device with a user-installed certificate:

```
(host) [mynode] (config) #local-custom-cert local-mac 00:16:CF:AF:3E:E1 ca-  
cert cacert1 server-cert servercert1
```

Related Commands

Command	Description
show local-cert-mac	Display the IP, MAC address and certificate configuration of managed devices.

Command History

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Available on all platforms	The suite-b gcm-128 and suite-b gcm-256 encryption options for IPsec custom certificates requires the Advanced Cryptography license. All other parameters are available in the base operating system.	Config mode on Mobility Conductor.

local-factory-cert

```
local-factory-cert local-mac <lmac> [load-balance]
```

Description

This command configures the factory-installed certificate for communication between a managed device and a Mobility Conductor. Use this command on a Mobility Conductor to configure the factory certificate for communication with a managed device. On the managed device, use the `masterip` command to configure the IP address and certificates for the Mobility Conductor. If your Mobility Conductor and managed devices use certificates for authentication, the IPsec tunnel will be created using IKEv2. When a managed device communicates with Mobility Conductor to set up IPsec tunnels, the uplink vlan tag configured via the [uplink](#) command will be sent along in vendor-id payload during IKE negotiation. This will uniquely bind the tunnel from a particular uplink on the managed device to a corresponding map on Mobility Conductor.

Parameter	Description
<lmac>	MAC address of the managed device with a local certificate.

Example

The following command configures the managed device with a factory-installed certificate:

```
(host)[node](config) #local-factory-cert local-mac 00:16:CF:AF:3E:E1
```

localip

```
localip <ipaddr>  
    ipsec <key>
```

Description

This command configures the IP address and preshared key for the managed device on a Mobility Conductor. Use this command on a Mobility Conductor to configure the IP address and preshared key or certificates for communication with a managed device. On the managed device, use the **masterip** command to configure the IP address and preshared key for the Mobility Conductor.

If your Mobility Conductor and managed devices use a PSK for authentication, they will create the IPsec tunnel using IKEv1.

Parameter	Description
<ipaddr>	IP address of the managed device. Use the 0.0.0.0 address to configure a global preshared key for all inter-managed device communications.
ipsec <key>	To establish the master/conductor-local IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.

Example

The following command configures the managed device with a PSK:

```
(host) [mynode] (config) #localip 0.0.0.0 ipsec gw1234xyz
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command Introduced.

Command Information

localipv6

```
localipv6 <local-switch-ipv6>  
    ipsec <key>
```

Description

This command configures the IP address and preshared key for the managed device on a Mobility Conductor. Use this command on a Mobility Conductor to configure the IP address and preshared key or certificates for communication with a managed device. On the managed device, use the `masterip` command to configure the IP address and preshared key for the Mobility Conductor.

If your Mobility Conductor and managed devices use a PSK for authentication, they will create the IPsec tunnel using IKEv1.

Parameter	Description
<local-switch-ipv6>	IP address of the managed device. Use the 0.0.0.0 address to configure a global PSK for communication between managed devices.
ipsec <key>	To establish the master/conductor-local IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.
localipv4 <localipv4_val>	IPv4 address of the managed device. NOTE: The configuration of the <code>localipv4 <localipv4_val></code> sub-parameter is optional in a native IPv6 deployment.

Example

The following command configures the managed device with a PSK:

```
(host) [mynode] (config) #localipv6 2001:0000:0eab:DEAD:0000:00AO:ABCD:004E  
ipsec gw1234xyz
```

Command History

local-peer-mac

```
local-peer-mac <local-mac-addr> ipsec <localkey>
```

Description

This command is used to configure security peer-mac based between Mobility Conductor and managed devices.

Parameter	Description
<local-mac-addr>	Enter the managed device's MAC address.
ipsec <localkey>	Configure the value of the IKE PSK, it must be between 6-64 characters

Example

The following command configures the security peer-mac:

```
(host) [mynode] (config) #local-peer-mac 00:0c:29:00:00:00 ipsec 123456
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

  opt-field-3
  opt-field-4
  remote-ip
  role
  sponsor-dept
  sponsor-email
  sponsor-fullname
  sponsor-name
  start-time
```

Description

This command creates a user account entry in Mobility Conductor's internal database. When you specify the internal database as an authentication server, client information is checked against the user accounts in the internal database. You can modify an existing user account in the internal database with the `local-userdb modify` command, or delete an account with the `local-userdb del` command.

By default, the internal database in Mobility Conductor is used for authentication. Issue the `aaa authentication-server internal use-local-switch` command to use the internal database in

a managed device; you then need to add user accounts to the internal database in the managed device.

Parameter	Description
generate-username	Automatically generate and add a username.
username	Add the specified username. 1-64 characters
generate-password	Automatically generate a password for the username.
password	Add the specified password for the username. 6-128 characters
comments	Comments added to the user account.
email	Email address for the user account.
expiry	Expiration for the user account. If this is not set, the account does not expire. no expiration
duration	Duration, in minutes, for the user account. 1-2147483647
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Aruba wireless network.
guest-fullname	The guest's full name.
guest-phone	The guest's phone number.
mode	Enables or disables the user account. disabled
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.
opt-field-2	Same as opt-field-1 .

Parameter	Description
opt-field-3	Same as opt-field-1 .
opt-field-4	Same as opt-field-1 .
remote-ip	IP address assigned to the remote peer.
role	Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method. guest
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.
sponsor-email	The sponsor's email address.
sponsor-fullname	The sponsor's full name.
sponsor-name	The sponsor's name.
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.

Example

The following command adds a user account in the internal database with an automatically-generated username and password:

```
(host) [mynode] #local-userdb add generate-username generate-password expiry
duration 480
```

The following information is displayed when you enter the command:

```
GuestConnect
Username: guest4157
Password: cDFD1675
Expiration: 480 minutes
```

Related Commands

Command	Description
mgmt-user	Use the <code>webui-cacert <certificate name></code> command if you want an external authentication server to derive the management user role. This is helpful if there are a large number of users who need to be authenticated. Use the <code>mgmt-user webui-cacert <certificate_name> serial <number> <username> <role></code> command if you want the authentication process to use previously configured certificate name and serial number to derive the user role.
show local-userdb	Use this command to show the parameters displayed in the output of this command.
show local-userdb-guest	Use this command to show the parameters displayed in the output of the local-userdb-guest add command.

    opt-field-4
    remote-ip
    role
    sponsor-dept
    sponsor-email
    sponsor-fullname
    sponsor-name
    start-time
del-all
```

Description

This command deletes entries in the Mobility Conductor's internal database. User account entries created with expiration are automatically deleted from the internal database at the specified expiration. Use this command to delete an entry before its expiration or to delete an entry that was created without an expiration.

Parameter	Description
del username	Deletes the user account for the specified username.
comments	Comments added to the user account.
email	Email address for the user account.
expiry	Expiration for the user account. If this is not set, the account does not expire. no expiration NOTE: This parameter is available only for AOS version 8.6 or earlier.
duration	Duration, in minutes, for the user account. 1-2147483647

Parameter	Description
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Aruba wireless network.
guest-fullname	The guest's full name.
guest-phone	The guest's phone number.
mode	Enables or disables the user account. disabled NOTE: This parameter is available only for AOS version 8.6 or earlier.
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.
opt-field-2	Same as opt-field-1 .
opt-field-3	Same as opt-field-1 .
opt-field-4	Same as opt-field-1 .
remote-ip	IP address assigned to the remote peer. NOTE: This parameter is available only for AOS version 8.6 or earlier.
role	Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method. guest
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.
sponsor-email	The sponsor's email address.

Parameter	Description
sponsor-fullname	The sponsor's full name.
sponsor-name	The sponsor's name.
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins. NOTE: This parameter is available only for AOS version 8.6 or earlier.
del-all	Deletes all entries in the internal database.

Example

The following command deletes a specific user account entry:

```
(host) [mynode] #local-userdb del username guest4157
```

Command History

local-userdb export

```
local-userdb export <filename>
```

Description

This command exports the internal database to a file. After using this command, you can use the `copy` command to transfer the file from flash to another location.

Use this command with caution. It replaces the existing users with user entries from the imported file.

Parameter	Description
export	Saves the internal database to the specified file in flash.

Example

The following command saves the internal database to a file:

```
(host) [mynode] #local-userdb export jan-userdb
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

  opt-field-3
  opt-field-4
  remote-ip
  role
  sponsor-dept
  sponsor-email
  sponsor-fullname
  sponsor-name
  start-time
```

Description

This command modifies an existing user account entry in the Mobility Conductor's internal database. Use the `show local-userdb` command to view the current user account entries in the internal database.

Parameter	Description
<code>username</code>	Name of the existing user account entry. 1-64 characters
<code>comments</code>	Comments added to the user account.
<code>email</code>	Email address for the user account.
<code>expiry</code>	Expiration for the user account. If this is not set, the account does not expire. no expiration
<code>duration</code>	Duration, in minutes, for the user account. 1-2147483647
<code>time</code>	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.
<code>guest-company</code>	Name of the guest's company.

Parameter	Description
	NOTE: A guest is the person who needs guest access to the company's Aruba wireless network.
guest-fullname	The guest's full name.
guest-phone	The guest's phone number.
mode	Enables or disables the user account. disabled
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.
opt-field-2	Same as opt-field-1 .
opt-field-3	Same as opt-field-1 .
opt-field-4	Same as opt-field-1 .
remote-ip	IP address assigned to the remote peer.
role	Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method. guest
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.
sponsor-email	The sponsor's email address.
sponsor-fullname	The sponsor's full name.
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.

Example

The following command disables an existing user account in the internal database:

```
(host) [mynode] #local-userdb modify username guest4157 mode disable
```

  sponsor-email
  sponsor-fullname
  sponsor-name
  start-time
```

Description

This command creates a guest user in a local user database. When you specify the internal database as an authentication server, client information is checked against the user accounts in the internal database. You can modify an existing user account in the internal database with the `local-userdb-guest modify` command, or delete an account with the `local-userdb-guest del` command. By default, the internal database in the Mobility Conductor is used for authentication. Issue the `aaa authentication-server internal use-local-switch` command to use the

internal database in a managed device you then need to add user accounts to the internal database in the managed device.

Parameter	Description
generate-username	Automatically generate and add a guest username.
username	Add the specified guest username. 1-64 characters
generate-password	Automatically generate a password for the username.
password	Add the specified password for the username. 6-128 characters
comments	Comments added to the user account.
email	Email address for the user account.
expiry	Expiration for the user account. If this is not set, the account does not expire. no expiration
duration	Duration, in minutes, for the user account. 1-2147483647
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Aruba wireless network.
guest-fullname	The guest's full name.
guest-phone	The guest's phone number.
mode	Enables or disables the user account. disabled
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.
opt-field-2	Same as opt-field-1 .

Parameter	Description
opt-field-3	Same as opt-field-1 .
opt-field-4	Same as opt-field-1 .
remote-ip	IP address assigned to the remote peer. NOTE: This parameter is available only for AOS version 8.6 or earlier.
role	Role for the user. This role takes effect when the internal database is specified in a server group profile with a server derivation rule. If there is no server derivation rule configured, then the user is assigned the default role for the authentication method. guest NOTE: This parameter is available only for AOS version 8.6 or earlier.
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.
sponsor-email	The sponsor's email address.
sponsor-fullname	The sponsor's full name.
sponsor-name	The sponsor's name.
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.

Example

The following command adds a guest user in the internal database with an automatically-generated username and password:

```
(host) [mynode] #local-userdb-guest add generate-username generate-password
expiry none
```

The following information is displayed when you enter the command:

```
GuestConnect
Username: guest-5433352
Password: mBgJ6764
Expiration: none
```

local-userdb-guest del

```
local-userdb-guest {del username <name> | del-all}
```

Description

This command deletes entries in the controller's internal database. User account entries created with expiration detail are automatically deleted from the internal database at the specified expiration. Use this command to delete an entry before its expiration or to delete an entry that was created without an expiration.

Parameter	Description
del username	Deletes the user account for the specified username.
comments	Comments added to the user account.
email	Email address for the user account.
grantor	Change the grantor of the guest user entry
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Aruba wireless network.
guest-fullname	The guest's full name.
guest-phone	The guest's phone number.
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.
opt-field-2	Same as opt-field-1 .
opt-field-3	Same as opt-field-1 .
opt-field-4	Same as opt-field-1 .
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.
sponsor-email	The sponsor's email address.

Parameter	Description
sponsor-fullname	The sponsor's full name.
sponsor-name	The sponsor's name.
del-all	Deletes all entries in the internal database.

Example

The following command deletes a specific user account entry:

```
(host) #local-userdb-guest del username guest4157
```

Command History

local-userdb-guest modify

```
local-userdb-guest modify username <name> [comments <g_comments>][email <email>]
[expiry {duration <minutes>|time <mm/dd/yyyy> <hh:mm>}] [guest-company <g_company>]
[guest-fullname <g_fullname>][guest-phone <g-phone>][mode disable][opt-field-1
<opt1>][opt-field-2 <opt2>][opt-field-3 <opt3>][opt-field-4 <opt4>][password
<passwd>][sponsor-dept <sp_dept>][sponsor-mail <sp_email>][sponsor-fullname <sp_
fullname>][sponsor-name <sp_name>][start-time <mm/dd/yyyy> <hh.mm>]
```

Description

This command modifies an existing guest user entry in the controller's internal database. Use the **show local-userdb-guest** command to view the current user account entries in the internal database.

Parameter	Description
username	Name of the existing user account entry. 1-64 characters
comments	Comments added to the user account.
email	Email address for the user account.
expiry	Expiration for the user account. If this is not set, the account does not expire. no expiration
grantor	Change the grantor of the guest user entry
duration	Duration, in minutes, for the user account. 1-2147483647
time	Date and time, in mm/dd/yyyy and hh:mm format, that the user account expires.
guest-company	Name of the guest's company. NOTE: A guest is the person who needs guest access to the company's Aruba wireless network.
guest-fullname	The guest's full name.
guest-phone	The guest's phone number.
mode	Enables or disables the user account. Disable

Parameter	Description
opt-field-1	This category can be used for some other purpose. For example, the optional category fields can be used for another person, such as a "Supervisor." You can enter username, full name, department and Email information into the optional fields.
opt-field-2	Same as opt-field-1 .
opt-field-3	Same as opt-field-1 .
opt-field-4	Same as opt-field-1 .
password	User's password. 1-6 characters
sponsor-dept	The guest sponsor's department name. NOTE: A sponsor is the guest's primary contact for the visit.
sponsor-email	The sponsor's email address.
sponsor-fullname	The sponsor's full name.
sponsor-name	The sponsor's name.
start-time	Date and time, in mm/dd/yyyy and hh:mm format, the guest account begins.

Example

The following command disables a guest user account in the internal database:

```
(host) #local-userdb-guest modify username guest4157 mode disable
```

local-userdb-guest send-email

```
local-userdb-guest send-email <username> [to-guest][to-sponsor]
```

Description

This command causes the controller to send email to the guest or sponsor any time a guest user is created. This command ensures that the controller sends an email to the guest or sponsor any time a guest user is created.

Parameter	Description
<username>	Name of the guest. 1-64 characters
to-guest	Allows you to send email to the guest user's address.
to-sponsor	Allows you to send email to the sponsor's email address.

Example

The following command causes the controller to send an email to the sponsor alerting them that the guest user **Laura** was just created.

```
(host)# local-userdb-guest send-email Laura to-sponsor
```

local-userdb-public-access

```
local-userdb
  del username <name>
  del-all
```

Description

This command deletes guest entries in the Mobility Conductor's internal database. User account entries created with expiration are automatically deleted from the internal database at the specified expiration. Use this command to delete an entry before its expiration or to delete an entry that was created without an expiration.

Parameter	Description
del username	Deletes a guest user account for the specified username.
del-all	Deletes all guest entries in the internal database.

Example

The following command deletes a specific guest account entry:

```
(host) [mynode] #local-userdb-public-access del username guest4157
```

local-userdb maximum-expiration

```
local-userdb maximum-expiration <expmins>
```

Description

This command configures the maximum time, in minutes, that a guest account in the internal database can remain valid. The user in the guest-provisioning role cannot create guest accounts that expire beyond the configured maximum time. This command is not available to the user in the guest-provisioning role.

Parameter	Description
maximum-expiration	Maximum time, in minutes, that a guest account in the internal database can remain valid. 1-3000000

Example

The following command sets the maximum time for guest accounts in the internal database to 8 hours (480 minutes):

```
(host) [/md] (config) #local-userdb maximum-expiration 480
```

local-userdb send-to-guest

local-userdb send-to-guest

Description

This command automatically sends email to the guest when the guest user is created.

A guest is the person who needs guest access to the company's Aruba wireless network. Email is sent directly to the guest after the guest user is created. When configuring the guest provisioning feature, the guest user is generally created by Guest Provisioning user. This is the person who is responsible for signing in guests at your company.

Example

```
(host) [mynode] (config) #local-userdb send-to-guest
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

location

location <switchlocation>

Description

This command configures the location of the managed device. Use this command to indicate the location of the managed device. You can use a combination of numbers, letters, characters, and spaces to create the name. To include a space in the name, use quotation marks to enclose the text string.

To change the existing name, enter the command with a different string. To unconfigure the location, enter "" at the prompt.

Parameter	Description
switchlocation	A text string that specifies the location of the switch.

Example

The following command configures the location:

```
(host) [mynode] (config) #location "Building 10, second floor, room 21E"
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

location-server-feed

enable
disable

Description

This command sends RSSI information from APs to a location management server, which can use that information to compute the location of stations seen in the network.

Parameter	Description
enable	Enable the feed that sends RSSI information to a location management server. This feature is disabled by default.
disable	Disable the feed that sends RSSI information to a location management server. This feature is disabled by default.

Example

The following command configures the location:

```
(host) [mynode] (config) #location-server-feed enable
```

Command History

logging

```
logging [ap-debug|arm|arm-user-debug|facility|network|peer-  
debug|security|system|user|user-debug|wireless|<ipv4addr>|<ipv6addr>]
```

Description

Use this command to specify the IP address of the remote logging server, facility, severity, and the type. The local use facilities (local0, local1, local2, local3, local4, local5, local6, and local7) are not reserved for specific message-generating sources, and can be used for sending syslog messages. Use the [show logging](#) command to verify that the device sends logging messages.

There are eight logging severity levels, each with its associated types of messages. Each level also includes the levels below it. For example, if you set the logging level to informational (6), all messages from level 0 through level 5 (from emergencies through notifications) are also logged. The warnings severity level is set by default for all message categories.

Only the **logging level warnings security subcat ids** and **logging level warnings security subcat ids-ap** subcategories are enabled by default. Other subcategories are not generated by default even their severity is **warning** or higher.

Parameter	Description
ap-debug <name>	AP troubleshooting messages. You must specify a debug value.
arm level process subcat	ARM messages.
arm-user-debug <mac>	ARM user troubleshooting messages. You must specify a MAC address.
facility	Set the facility to be used when logging to the remote syslog server. The local use facilities (local0, local1, local2, local3, local4, local5, local6, and local7) are not reserved for specific message-generating sources, and can be used for sending syslog messages. local 0 to local 7
network level process subcat	Network messages.
peer-debug <mac>	Peer Debug Logs.
security level	Security messages.

Parameter	Description
process subcat	
system level process subcat	System messages.
user level process subcat	User messages.
user-debug <mac>	User troubleshooting messages. You must specify a MAC address.
wireless level process subcat	Wireless messages.
<ipv4addr>	To set the remote logging server IPv4 address. A.B.C.D
dest-port <destination-port>	Select destination port for Syslog messages to this IP address.
facility	The facility to be used when logging to a remote syslog server. local 0 to local 7
format	The format of the logs when logging to a remote syslog server. <ul style="list-style-type: none"> ▪ cef - Common Event Fformat ▪ bsd-standard - Berkeley Software Distribution standard or RFC-3164 format
severity	Set the remote logging server severity to: <ul style="list-style-type: none"> ▪ alerts - Immediate action required ▪ critical - Critical Condition ▪ debugging - Debug Messages ▪ emergencies - System is unusable ▪ errors - Error Conditions in the system ▪ informational - Informational Messages ▪ notifications - Normal but significant condition ▪ warnings - Warning condition
source-interface <VLAN number>	Select source address of outgoing Syslog messages.

Parameter	Description
tls	Enable TLS option for rsyslog.
type	Set the remote logging server message type to: <ul style="list-style-type: none"> ▪ ap-debug - AP Debug Logs ▪ arm - ARM logs ▪ arm-user-debug - ARM User Debug Logs ▪ network - Network logs ▪ security - Security logs ▪ system - System logs ▪ user - User logs ▪ user-debug - User Debug Logs ▪ wireless - Wireless logs
<ipv6addr>	To set the remote logging server IPv6 address. X:X:X:X::X
dest-port <destination-port>	Select destination port for Syslog messages to this IP address.
facility	The facility to be used when logging to a remote syslog server. local 0 to local 7
format	The format of the logs when logging to a remote syslog server. <ul style="list-style-type: none"> ▪ cef - Common Event Fformat ▪ bsd-standard - Berkeley Software Distribution standard or RFC-3164 format
severity	Set the remote logging server severity to: <ul style="list-style-type: none"> ▪ alerts - Immediate action required ▪ critical - Critical Condition ▪ debugging - Debug Messages ▪ emergencies - System is unusable ▪ errors - Error Conditions in the system ▪ informational - Informational Messages ▪ notifications - Normal but significant condition ▪ warnings - Warning condition
type	Set the remote logging server message type to: <ul style="list-style-type: none"> ▪ ap-debug - AP Debug Logs ▪ arm - ARM logs ▪ arm-user-debug - ARM User Debug Logs ▪ network - Network logs ▪ security - Security logs ▪ system - System logs

Parameter	Description
	<ul style="list-style-type: none"> ▪ user- User logs ▪ user-debug - User Debug Logs ▪ wireless - Wireless logs
level	<p>The message severity level, which can be one of the following (in order of severity level):</p> <ul style="list-style-type: none"> ▪ alerts - Any condition requiring immediate attention and correction. ▪ critical - Any critical conditions, such as hard drive errors. ▪ debugging - Messages containing information for debugging purposes. ▪ emergencies - Panic conditions that occur when the system becomes unstable. ▪ errors - Error conditions. ▪ informational - Significant events of a non-critical and normal nature. ▪ notifications - Normal but significant condition. ▪ warnings - Warning messages.
process	<p>controller process, which can be one of the following:</p> <ul style="list-style-type: none"> ▪ aaa - AAA logging ▪ activate - Integration and communication with an Activate server ▪ amon_recvr - AMON receiver ▪ amon_sender - AMON sender ▪ apprf - APPRF feature ▪ approc - AP processes ▪ armd - ARM processes ▪ authmgr - User authentication ▪ ble_relay - BLE relay process ▪ bocmgr - BOC manager process ▪ cert_dwnld - Certificate download process ▪ certmgr - Certificate manager ▪ cfgdist - Config Distributor ▪ cfgm - Configuration Manager ▪ cli - Command Line Interface ▪ cluster_mgr - Cluster Manager ▪ cpsec - Control plane security ▪ crypto - VPN (IKE/IPsec) ▪ cts - Transport service ▪ dbsync - Database synchronization ▪ dds - Logging for DDS processes ▪ dhcpd - DHCP packets ▪ dpagent - DPAGENT process

Parameter	Description
	<ul style="list-style-type: none"> ▪ esi - External Services Interface ▪ extifmgr - External Interface Manager ▪ fpapps - Layer 2 and 3 control ▪ fw_visibility - Firewall visibility processes ▪ gsmmgr - GSM manager ▪ ha_mgr - High availability manager ▪ hcm - Health check process ▪ httpd - Apache process ▪ hwmon - Hardware monitoring ▪ iapmgr - Instant AP manager process ▪ ip_flow_export - IP Flow Export process ▪ ipstm - Instant station manager process ▪ l2tp - L2TP ▪ lagm - Logging for lagm process ▪ licensmgr - License manager ▪ lldp - LLLDP process ▪ localdb - Local database ▪ mdns - Multicast DNS proxy ▪ mobileip - Mobile IP ▪ mon_serv - mon_serv process ▪ mon_serv_fwv - mon_serv_fwv process ▪ npppd - NPPPD ▪ ofa - OpenFlow Agent Process ▪ ospf - OSPF logging ▪ packetfilter - Packet filtering of messaging and control frames ▪ phonehome - PhoneHome ▪ pim - Protocol Independent Multicast ▪ pppd - PPP ▪ pppoe - PPPoE ▪ pptp - PPTP ▪ processes - Run-time process ▪ profmgr - Profile Manager ▪ publisher - Publish subscribe service ▪ radvd - RA daemon ▪ resolvwrap - Resolve wrap process ▪ rfm - RF Troubleshooting Manager ▪ rng_mgr - RNG Manager ▪ rsync - Rsync ▪ rtpa - RTPA process ▪ sc_replication_mgr - SC Replication Manager ▪ snmp - SNMP ▪ spectrum - Spectrum analysis processes ▪ stm - Station management ▪ survival - Auth survival

Parameter	Description
	<ul style="list-style-type: none"> ▪ syslogdwrap - Syslogd wrap ▪ traffic - Traffic process ▪ ucm - Unified Communication and Collaboration processes ▪ upgrademgr - Upgrade Manager ▪ util-proc - Util process ▪ vrrp - Logging for vrrp process ▪ web_cc - Web Content classification ▪ webd - Web Daemon. ▪ wms - Wireless management
subcat	<p>Message subcategory, which depends upon the message category specified. The following lists the subcategories available for each message category:</p> <ul style="list-style-type: none"> ▪ ap-debug: all, ap-config, ha, sdn ▪ arm: all, client-match, radio-mgmt ▪ arm-user-debug: all ▪ network: all, cluster, dhcp, gp, mobility, packet-dump, sdn ▪ security: aaa, all, auth-amon, certinit, certmgr, cluster, cpnw, cpsec, db, 802.1X, firewall, HA, ids, ids-ap, kerberos, mobility, packet-trace, vpn, webserver, wl-sync ▪ system: all, amon, amon-ale, amon-amp, ap, ap-config, cluster, configuration, cpnw, gp, ha, mapc, messages, ofc-event-dispatcher, ofc-flow-manager, ofc-packet-dispatcher, ofc-routing-switch, ofc-switch-manager, ofc-topology, ofc-topology-discovery, pan, reg-tbl, snmp, validation, webserver ▪ user: all, captive-portal, client-match, cpnw, 802.1X, mapc, pan, radius, vpn ▪ user-debug: all, configuration ▪ wireless: all

Example

The following command adds the remote logging server with the IP address 10.1.2.3 with a user log type using local4.

```
(host) [mynode] (config) #logging 10.1.2.3 facility local4
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The <code>tls</code> subparameter was introduced.
ArubaOS 8.7.0.0	The <code>peer-debug</code> parameter was introduced.
ArubaOS 8.2.0.0	New system processes called vrrp and lagm were added to debug issues related to the <code>vrrp</code> process and <code>lagm</code> process.
ArubaOS 8.1.0.0	The logging level <severity> was moved to the end of the command string. The <code>format</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Platforms	License	Command Mode
Available on all platforms	Base operating system.	Config mode on Mobility Conductor.

logging-trace-files

logging-trace-files

Description

Use this command to enable or disable the slog_flash application. The slog_flash application continuously updates log files to the USB storage. An error occurs when the USB storage is removed when the update is in progress. This command is introduced to prompt the user before removing the external USB, to avoid this error.

Example

The following command disables slog_flash app.

```
(host) [mynode] #no logging-trace-files
```

Command History

Release	Modification
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
7200 Series, 7030, and 7010	Base operating system.	Config mode on Mobility Conductor.

login session

login session timeout <minutes>

Description

This command configures the time management session (via Telnet or SSH) remains active without user activity. The management user must re-login to the controller after a Telnet or SSH session times out. If you set the timeout value to 0, sessions do not time out. The TCP session timeout for wireless and wired user sessions through the controller is 15 minutes; this timeout for user sessions is not configurable.

Parameter	Description
timeout	Number of seconds or minutes that a management session remains active without any user activity. 1-60 minutes or 5-3600 seconds, 0 to disable 15 minutes

Example:

The following command configures management sessions on the controller to not time out:

```
(host) [mynode] (config) #login session timeout 0
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Requires the PEFNG license.	Config mode on Mobility Conductor.

logon

logon <device-ip>

Description

This command remotely logs in to the managed device CLI from the Mobility Conductor CLI. Ensure that the managed device is reachable from Mobility Conductor.

Parameter	Description
device-ip	IP address of the managed device.

Example

This command remotely logs in to the managed device CLI from the Mobility Conductor CLI.

```
(host) [mynode] (config) #logon 192.0.2.38
Last login: Wed Jun 29 08:23:33 2016 from 192.0.2.34
(host-md) #
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

mac-address-table

```
mac-address-table static <macaddr> gigabitethernet <slot/module/port> vlan <vlan>
```

Description

This command adds a static entry to the MAC address table. The MAC address table is used to forward traffic between ports on the controller. The table includes addresses learned by the controller. This command allows you to manually enter static addresses that are bound to specific ports and VLANs.

Parameter	Description
<macaddr>	MAC address, in the format xx:xx:xx:xx:xx:xx.
<slot/module/port>	Interface in <slot>/<module>/<port> format.
vlan	ID number of the VLAN. 1-4094

Example

The following command configures a MAC address table entry:

```
(host) [mynode] (config) #mac-address-table static 00:0b:86:f0:05:60  
gigabitethernet 0/0/12 vlan 22
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Config mode on Mobility Conductor and managed device.

master-l3redundancy/conductor-l3redundancy

```
master-l3redundancy/conductor-l3redundancy
l3-peer-ip-address {[<ipv4-addr>|<ipv6-addr>]} [ipsec <key>] [ipsec-custom-cert
<peer-mac> <MAC address> {ca-cert <certificate> | peer-mac-2 <MAC address>}]
[ipsec-factory-cert <peer-mac> <MAC address>]}
l3-sync-state {None|Primary|Secondary}
l3-sync-time <timer>
no...
```

Description

Use this command to configure and enable Layer-3 redundancy for a Mobility Conductor. Peer-ip and sync-state functions are required for proper functioning of Layer-3 redundancy. They have to be individually executed in **/mm/mynode** of all the Mobility Conductors involved in the redundancy.

Parameter	Description
l3-peer-ip-address	Configure L3 peer's ip address.
<ipv4-addr>	Configure ipv4 address of the peer Mobility Conductor.
<ipv6-addr>	Configure ipv6 address of the peer Mobility Conductor.
ipsec	Configure IPsec secure communication between Mobility Conductors.
ipsec-custom-cert	Customer certificate-based IPsec secure communication between Mobility Conductors.
ipsec-factory-cert	Factory certificate-based IPsec secure communication between Mobility Conductors.
l3-sync-state	Sync state for L3 Redundancy .
None	No Sync state for L3 Redundancy.
Primary	Set Sync state for L3 Redundancy as Primary.
Secondary	Set Sync state for L3 Redundancy as Secondary.
l3-sync-time	Sync Time for L3 Redundancy.
timer	Sync time in Hours. Value is between (2-24) hours. 2 hours
no	Negates any configured parameter.

Example

The following command enables you to configure Layer-3 redundancy.

```
(host) *[mynode] (config) #master-l3redundancy/conductor-l3redundancy
(host) *[mynode] (config-submode)# #l3-peer-ip-address
(host) *[mynode] (config-submode)#l3-sync-state
(host) *[mynode] (config-submode)#l3-sync-time
```

The following example configures Layer-3 redundancy for IPv6 address using custom-installed certificate on the Mobility Conductors:

```
(host) *[mynode] (config) #master-l3redundancy/conductor-l3redundancy
(host) *[mynode] (config-submode)# #l3-peer-ip-address 2021:1:1:166::254
ipsec-custom-cert peer-mac 00:0c:29:42:4c:b6 ca-cert L3-Primarysecondary-
CA server-cert L3-Secondary suite-b gcm256
```

The following example configures Layer-3 redundancy for IPv6 address using factory-installed certificate on the Mobility Conductors:

```
(host) *[mynode] (config) #master-l3redundancy/conductor-l3redundancy
(host) *[mynode] (config-submode)# #l3-peer-ip-address 2001:78::245 ipsec-
factory-cert peer-mac 20:4c:03:0e:e1:68
```

The following example configures Layer-3 redundancy for IPv6 address using IPsec secure communication between the Mobility Conductors:

```
(host) *[mynode] (config) #master-l3redundancy/conductor-l3redundancy
(host) *[mynode] (config-submode)# #l3-peer-ip-address 2021:1:1:145::109
ipsec itsabug
```

master-redundancy master-vrrp/conductor-redundancy conductor-vrrp

```
master-redundancy/conductor-redundancy
master-vrrp/conductor-vrrp [ipv6 | <id>]
no...
peer-ip-address [ipv6 <X:X:X:X::X>|ipv4]
```

Description

This command associates a VRRP instance with Mobility Conductor redundancy. To maintain a highly redundant network, you can use a standby Mobility Conductor. The underlying protocol used is VRRP, which you configure using the `vrrp` command.

Parameter	Description
<code>master-vrrp/conductor-vrrp</code>	Configure the virtual router ID of the master/conductor switch.
<code>ipv6</code>	The VRRP IPv6 address to establish an IPv6 IPsec tunnel.
<code><id></code>	The virtual router ID for the VRRP instance configured with the <code>vrrp</code> command. 1-255
<code>no</code>	Negates any configured parameter.
<code>peer-ip-address <ipv6 ipv4></code>	Configure peer IPv4 or IPv6 address.

Example

The following command configures VRRP IPv4 address for the initially preferred Mobility Conductor:

```
(host)[mynode](config) #vrrp 22
vlan 22
ip address 10.200.22.254
priority 110
preempt
description Preferred-Master/Conductor
tracking master-up-time//conductor-up-time 30 add 20
no shutdown
master-redundancy/conductor-redundancy
master-vrrp/conductor-vrrp 22
peer-ip-address 192.168.2.1 ipsec qwerty012
```

The following shows the corresponding VRRP IPv4 address configuration for the peer controller.

```
(host)[mynode](config) #vrrp 22
vlan 22
ip address 10.200.22.254
priority 100
preempt
description Backup-Master/Conductor
tracking master-up-time/conductor-up-time 30 add 20
no shutdown
master-redundancy/conductor-redundancy
master-vrrp/conductor-vrrp 22
peer-ip-address 192.168.22.1 ipsec qwerTY012
```

```

Description

This command configures the IP address and PSK or certificate for the Mobility Conductor on a managed device. Use this command on a managed device to configure the IP address and preshared key or certificate for secure communication with the Mobility Conductor. On the Mobility Conductor, use the `localip` command to configure the IP address and pre-shared key or certificate for a managed device.

The parameters in this command can also be defined using the initial setup wizard when the managed device is first configured. Best practices is to define masterip settings using this wizard. If the IP address of the Mobility Conductor on a managed device is changed the managed device should be rebooted.

If your Mobility Conductor and managed devices use a pre-shared key for authentication, they will create the IPsec tunnel using IKEv1. If your Mobility Conductor and managed devices use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Parameter	Description
<ipaddr>	IP address of the Mobility Conductor.
ipsec <key>	To establish the IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.
fqdn <fqdn>	Identify a dynamically addressed managed device by entering the FQDN of the Mobility Conductor.
interface	Specify the uplink or VLAN interface on the Mobility Conductor to initiate IKE.
peer-mac-1 <peermac-1>	Specify the peer MAC string. NOTE: The peer device is an x86 server, then configure the MAC address of the management interface of the managed device. However, if the peer device is a hardware platform, you must provide the MAC address of the VLAN interface of the managed device.

Parameter	Description
<code>ipsec-custom-cert</code>	Use a custom-installed certificate on the Mobility Conductor to establish a IPsec tunnel using IKEv2.
<code>master-mac1 <mac1></code>	Specify the MAC address of the certificate on the Mobility Conductor.
<code>master-mac2 <mac2></code>	(Optional) Specify the MAC address of the certificate on the redundant Mobility Conductor.
<code>ca-cert <ca></code>	User-defined name of a trusted CA certificate installed on the Mobility Conductor. Use the <code>show crypto-local pki TrustedCA</code> command to display the CA certificates that have been imported into the Mobility Conductor.
<code>server-cert <cert></code>	User-defined name of a server certificate installed on the Mobility Conductor. Use the <code>show crypto-local pki ServerCert</code> command to display the server certificates that have been imported into the Mobility Conductor.
<code>interface</code>	Specify the uplink or VLAN interface on the Mobility Conductor to initiate IKE.
<code>uplink</code>	Use the Mobility Conductor's current active uplink to initiate IKE.
<code>vlan <id></code>	Specify a VLAN interface on the Mobility Conductor to initiate IKE. If you do not specify a VLAN, the managed device IP will be used.
<code>fqdn <fqdn></code>	Identify a dynamically addressed managed device by entering the FQDN of the managed device.
<code>suite-b</code>	If you configure your Mobility Conductor and managed devices to use IKEv2 and custom-installed certificates, you can optionally use Suite- B cryptographic algorithms for IPsec encryption. Specify one of the following options: <ul style="list-style-type: none"> ▪ <code>gcm-128</code> Use 128-bit AES-GCM Suite-B encryption ▪ <code>gcm-256</code> Use 256-bit AES-GCM Suite-B encryption
<code>ipsec-factory-cert</code>	Use the factory-installed certificate on the Mobility Conductor to establish a master/conductor-local IPsec tunnel using IKEv2.
<code>master-mac1 <mac1></code>	Specify the MAC address of the certificate on the Mobility Conductor.
<code>master-mac2 <mac2></code>	(Optional) The MAC address of the certificate on the backup Mobility Conductor.

Parameter	Description
interface	Specify the uplink or VLAN interface on the Mobility Conductor to initiate IKE.
uplink	Use the Mobility Conductor's current active uplink to initiate IKE.
vlan <id>	Specify a VLAN interface on the Mobility Conductor to initiate IKE. If you do not specify a VLAN, the managed device IP will be used.
fqdn <fqdn>	Identify a dynamically addressed managed device by entering the FQDN of the managed device.
suite-b	If you configure your Mobility Conductor and managed devices to use IKEv2 and custom-installed certificates, you can optionally use Suite- B cryptographic algorithms for IPsec encryption. Specify one of the following options: <ul style="list-style-type: none"> gcm-128 Use 128-bit AES-GCM Suite-B encryption gcm-256 Use 256-bit AES-GCM Suite-B encryption
vpn-ip <vpn-ip>	Specify the IP address of the VPN concentrator or the FQDN.
ipsec	Establish a IPsec secure communication between the conductor and the local.
ipsec-custom-cert	Use a custom-installed certificate on the Mobility Conductor to establish a IPsec secure communication between the master/ conductor and the local.
ipsec-factory-cert	Use a factory-installed certificate on the Mobility Conductor to establish a IPsec secure communication between the master/ conductor and the local.
web-socket-acp	Configure web-socket connection with ACP.

Example

The following commands configure the Mobility Conductor with a pre-shared key:

```
(host)[mynode] (config) #masterip/conductorip 10.1.1.250 ipsec gw1234567
```

  vpn-ipv6 <vpnipv6>
```

Description

This command configures the IPv6 address and pre-shared key or certificate for the Mobility Conductor or a managed device. Use this command on a managed device to configure the IP address and pre-shared key or certificate for secure communication with the Mobility Conductor. On the Mobility Conductor, use the `localip` command to configure the IP address and pre-shared key or certificate for a managed device.

ArubaOS reboots the managed device when the primary IPv6 address is changed on the managed device. However, a change in the secondary IPv6 address does not require a reboot of the managed device.

If your Mobility Conductor and managed devices use a pre-shared key for authentication, they will create the IPsec tunnel using IKEv1. If your Mobility Conductor and managed devices use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Parameter	Description
<ipaddr>	IP address of the Mobility Conductor.
ipsec <key>	To establish the IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.
fqdn <fqdn>	Identify a dynamically addressed managed device by entering the FQDN of the Mobility Conductor. NOTE: FQDN is currently not supported for IPv6 address.
interface	Specify the uplink or VLAN interface on the Mobility Conductor to initiate IKE.
uplink	Use the Mobility Conductor's current active uplink to initiate IKE.

Parameter	Description
<code>vlan <id></code>	Specify a VLAN interface on the Mobility Conductor to initiate IKE. If you do not specify a VLAN, the Mobility Conductor IP will be used.
<code>masteripv4 <masteripv4_val></code>	Configure the corresponding IPv4 address of the Mobility Conductor. NOTE: The configuration of the <code>masteripv4 <masteripv4_val></code> sub-parameter is optional in a native IPv6 deployment.
<code>peer-mac-1 <peermac-1></code>	Specify the peer MAC address on the primary Mobility Conductor.
<code>peer-mac-2 <peermac-2></code>	(Optional) Specify the peer MAC address on the redundant Mobility Conductor.
<code>ipsec-custom-cert</code>	Use a custom-installed certificate on the Mobility Conductor to establish a IPsec tunnel using IKEv2.
<code>master-mac1 <mac1></code>	Specify the MAC address of the certificate on the Mobility Conductor.
<code>master-mac2 <mac2></code>	(Optional) Specify the MAC address of the certificate on the redundant Mobility Conductor.
<code>ca-cert <ca></code>	User-defined name of a trusted CA certificate installed on the Mobility Conductor. Use the <code>show crypto-local pki TrustedCA</code> command to display the CA certificates that have been imported into the Mobility Conductor.
<code>server-cert <cert></code>	User-defined name of a server certificate installed on the Mobility Conductor. Use the <code>show crypto-local pki ServerCert</code> command to display the server certificates that have been imported into the Mobility Conductor.
<code>suite-b</code>	If you configure your master/ conductor and managed devices to use IKEv2 and custom-installed certificates, you can optionally use Suite-B cryptographic algorithms for IPsec encryption. Specify one of the following options: <ul style="list-style-type: none"> ▪ gcm-128 Use 128-bit AES-GCM Suite-B encryption ▪ gcm-256 Use 256-bit AES-GCM Suite-B encryption
<code>ipsec-factory-cert</code>	Use the factory-installed certificate on the Mobility Conductor to establish a master/ conductor -local IPsec tunnel using IKEv2.
<code>master-mac1 <mac1></code>	Specify the MAC address of the certificate on the Mobility Conductor.

Parameter	Description
master-mac2 <mac2>	(Optional) The MAC address of the certificate on the backup Mobility Conductor.
interface	Specify the uplink or VLAN interface on the Mobility Conductor to initiate IKE.
uplink	Use the Mobility Conductor's current active uplink to initiate IKE.
vlan <id>	Specify a VLAN interface on the Mobility Conductor to initiate IKE. If you do not specify a VLAN, the managed device IP will be used.
fqdn <fqdn>	Identify a dynamically addressed managed device by entering the FQDN of the managed device.
vpn-ipv6 <vpnipv6>	IPv6 address of the VPN concentrator to establish IPsec tunnel.

Example

The following command configures the Mobility Conductor with a pre-shared key:

```
(host) [00:0b:86:dd:87:00] (config) #masteripv6/conductoripv6 2001::1 ipsec
Aruba@123 masteripv4 10.20.1.1
```

The following command configures the managed device with an IPsec pre-shared key:

```
(host) *[mynode] (config) #masteripv6/conductoripv6 2021:1:1:146::9 ipsec
itsabug peer-mac-1 00:15:5D:14:1F:1C peer-mac-2 00:0C:29:BC:89:9B interface
vlan 147 masteripv4 10.16.146.9
```

The following command configures the managed device with a factory-installed certificate:

```
(host) *[mynode] (config) #masteripv6/conductoripv6 2001:77::40 ipsec-
factory-cert master-mac-1 20:4c:03:0e:d2:ec master-mac-2 20:4c:03:0e:d2:84
interface-f vlan-f 79 masteripv4 10.15.77.40
```

The following command configures the managed device with a custom-installed certificate:

```
(host) *[mynode] (config) #masteripv6/conductoripv6 2021:1:1:166::254 ipsec-
custom-cert master-mac-1 00:0c:29:42:4c:b6 ca-cert CA server-cert VMC-CERT
interface vlan 164 masteripv4 10.16.166.254
```

The following command configures the branch office controller with a factory-installed certificate:

```
(host) *[mynode] (config) #masteripv6/conductoripv6 2021:1:1:146::9 vpn-ipv6
2001:192:192:201::42 ipsec-factory-cert vpn-mac-1 00:0b:86:b5:6b:c7
interface vlan 172 masteripv4 10.16.146.9
```

The following command configures the branch office controller with an IPsec pre-shared key:

```
(host) *[mynode] (config) #masteripv6/conductoripv6 2021:1:1:166::254 vpn-
ipv6 2001:192:192:201::3 ipsec itsabug peer-id 20:4C:03:44:13:C8 interface vlan 2000
masteripv4 10.16.166.254
```

The following command configures the branch office controller with a custom-installed certificate:

```
(host) *[mynode] (config) #masteripv6/conductoripv6 2021:1:1:166::254 vpn-
ipv6 2001:192:192:201::11 ipsec-custom-cert vpn-mac-1-c 00:0b:86:b5:6b:c7
ca-cert-v BOC-CA server-cert-v BOC_cert interface vlan 172 masteripv4
10.16.166.254
```

Command History

Release	Modification
ArubaOS 8.6.0.0	The following parameters were added: <ol style="list-style-type: none"> 1. <code>vpn-ipv6 <vpnipv6></code> 2. <code>peer-mac-1 <peermac-1></code> 3. <code>peer-mac-2 <peermac-2></code>

    ipsec <key>
    ipsec-custom-cert peer-mac <mac> ca-cert <ca> server-cert <sc> [suite-b
    gcm128|gcm256]
    ipsec-factory-cert peer-mac <mac>
```

Description

This command configures the IP address and PSK or certificate for a redundant Mobility Conductor on another Mobility Conductor. Use this command on a Mobility Conductor to configure the IP address and pre-shared key or certificates for communication with a redundant Mobility Conductor. If your Mobility Conductor uses a pre-shared key for authentication, it will create the IPsec tunnel using IKEv1. If your Mobility Conductor and managed devices use certificates for authentication, the IPsec tunnel will be created using IKEv2.

Parameter	Description
<ipaddr>	The IPv4 address of the redundant Mobility Conductor. Use the 0.0.0.0 address to configure a global preshared key for all inter-controller communications.
ipv6 <ipv6-addr>	The IPv6 address of the redundant Mobility Conductor.
ipsec <key>	To establish the IPsec tunnel using IKEv1, enter a preshared key between 6-64 characters.
ipsec-custom-cert	Use a custom-installed certificate on the Mobility Conductor to establish the IPsec tunnel using IKEv2.
peer-mac <mac>	The peer MAC address of the certificate on the redundant Mobility Conductor.
ca-cert <ca>	User-defined name of a trusted CA certificate installed on the redundant Mobility Conductor. Use the <code>show crypto-local pki TrustedCA</code> command to display the CA certificates that have been imported into the controller.
server-cert <cert>	User-defined name of a server certificate installed on the redundant controller. Use the <code>show crypto-local pki ServerCert</code> command to display the server certificates that have been imported into the Mobility Conductor.

Parameter	Description
suite-b	If you configure your Mobility Conductor to use IKEv2 and custom-installed certificates, you can optionally use Suite-B cryptographic algorithms for IPsec encryption. Specify one of the following options: <ul style="list-style-type: none"> ▪ gcm-128 Use 128-bit AES-GCM Suite-B encryption ▪ gcm-256 Use 256-bit AES-GCM Suite-B encryption
ipsec-factory-cert	Use the factory-installed certificate on the Mobility Conductor to establish a master/ conductor -local IPsec tunnel using IKEv2.
peer-mac <mac>	The MAC address of the certificate on the redundant Mobility Conductor.

Example

The following command configures the managed device by using the IPv6 address of the redundant Mobility Conductor:

```
(host) [md] (config) #peer-ip-address ipv6 2001:1:2:2020::1 ipsec-custom-
cert master/conductor-mac 00:02:2D:11:55:4D ca-cert cacert1 server-cert
server1
```

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>master</code> have been replaced with <code>conductor</code> .
ArubaOS 8.6.0.0	The <code>ipv6 <ipv6-addr></code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	The suite-b gcm-128 and suite-b gcm-256 encryption options for IPsec custom certificates requires the Advanced Cryptography license. All other parameters are available in the base operating system.	Config mode on Mobility Conductor.

mdconnect

mdconnect

Description

This command allows a user to log in to a managed device without a username and password after logging in to a Mobility Conductor. Change the configuration node to a managed device and execute this command or **mdc**, its short-version to direct the session to the CLI prompt of the managed device. The keyword **MDC** is shown in the CLI prompt to distinguish the managed device and the Mobility Conductor. On the managed device, a user can issue only show commands. Use the `mdconnect` command to log in to a managed device without a username and password.

Parameter	Description
mdconnect	Log in to a managed device without a username and password.

Example

The following command allows a user to log in to a managed device named **VMC** mapped to a device with MAC address 01:02:03:04:05:06:

```
(host) [mynode] #change-config-node VMC
(MM) [01:02:03:04:05:06] #mdconnect

Redirecting to Managed Device Shell
Last login: Wed Nov 2 08:37:48 2016 from X.X.X.X
(VMC) [MDC] #exit

Exiting Managed Device Shell
(MM) [01:02:03:04:05:06] (config) #

The following command allows a user to log in to a managed device with MAC
address 0a:0b:0c:0d:0e:0f:
(host) [mynode] #change-config-node /md/0a:0b:0c:0d:0e:0f
(MM) [0a:0b:0c:0d:0e:0f] #mdconnect

Redirecting to Managed Device Shell
Last login: Wed Nov 2 08:38:48 2016 from X.X.X.X
(test) [MDC] #exit

Exiting Managed Device Shell
(MM) [0a:0b:0c:0d:0e:0f] (config) #
```

mesh-recovery-generate

```
mesh-recovery-generate
  {license <license> | serial <serial> mac <mac> }
  override
  unencrypted
```

Description

This command is used to generate a mesh recovery profile.

Parameter	Description
license <license>	Specify a license string or a 48 characters long string.
override	Override current recovery profile with the generated one. NOTE: Do 'write mem' to store the generated profile in the configuration file.
unencrypted	Display unencrypted wpa-hexkey (for debugging).
serial <serial>	Specify serial number of the controller.
mac <mac>	Specify MAC address of the controller.
override	Override current recovery profile with the generated one.

Parameter	Description
	NOTE: Do 'write mem' to store the generated profile in the configuration file.
unencrypted	Display unencrypted wpa-hexkey (for debugging).

Description

This command configures the management server profile. Register a management server with the Mobility Conductor by specifying the IP address of an AirWave management server or ALE that should receive messages from the Mobility Conductor using the AMON protocol. You must also specify the management configuration profile in which the AMON message filtering settings can be done. The default profiles provided for the AirWave server (default-amp) and ALE (default-ale) are editable using this command.

The IDS WLAN management system (WMS) on the managed device monitors wireless traffic to detect any new AP or wireless client station that tries to connect to the network. ArubaOS can send Clarity Live and user serviceability statistics from a managed device to a management server, which can use this data to identify the client connectivity issues.

A managed device can also collect information about each step in the user authentication process, and send these records to a management server in the AMON format, the data transport

protocol used to communicate basic statistics or state changes to the management servers such as AirWave or ALE.

Parameter	Description
primary-server <primary-server-ip> profile <profile-name> [secure transport]	Associate the Mobility Conductor to ALE server or an AirWave management server by entering the IPv4 or IPv6 address of the server and specifying a management configuration profile.
secure	Enabling this specifies that DTLS mode is used.
transport	This defines the type of transport mechanism.
profile	Configure a new management server profile on the Mobility Conductor or to edit the default profiles.
airgroupinfo-enable	If enabled, the messages related to the AirGroup feature will be sent to the management server.
ap-app-stats	Enables reporting client application usage.
app-stats	Enables AP statistics.
clone <source>	Copy from another management configuration profile.
generic-amon-enable	Enables Always On Amon messages.
inline-ap-stats	Enable Clarity Live statistics from the AP.
inline-auth-stats	Enable Clarity Live statistics related to authentication.
inline-ctrl-assoc-stats	Generates the passive controller station AMON messages. The passive controller station AMON messages are not generated by default. To generate the messages, issue the mgmt-server profile <name of the profile> inline-ctrl-assoc-stats command on managed device.
inline-dhcp-stats	Enable Clarity Live statistics of DHCP.
inline-dns-stats	Enable Clarity Live statistics of DNS.
inline-lldp-stats	Enable Clarity Live statistics of LLDP.
location-enable	If enabled, Station RSSI or AP Neighbor messages will be sent to the management server.
misc-enable	If enabled, the AP system statistics, specifications, and station steer information will be sent to the management server.

Parameter	Description
<code>monitored-info-del-enable</code>	Information is sent when a monitored AP or client is deleted.
<code>monitored-info-enable</code>	If enabled, the monitored AP or station information will be sent to the management server.
<code>monitored-info-snapshot-enable</code>	If enabled, the managed device sends a periodic snapshot about the state (up or down) of each monitored AP, client, rogue AP, or suspected rogue AP.
<code>no</code>	Negates or removes a parameter.
<code>sessions-enable</code>	If enabled, the firewall DNA, application, and aggregate session messages will be sent to the management server.
<code>stats-enable</code>	If enabled, the statistics for AP radios, virtual APs, and clients are be sent to the management server.
<code>stats-extended-enable</code>	If enabled, the extended statistics for AP radios, virtual APs, and clients are be sent to the management server.
<code>tag-enable</code>	If enabled, tag messages will be sent to the management server.
<code>uccmonitoring-enable</code>	If enabled, the messages about the unified communications manager are be sent to the management server.
<code>user-visibility-enable</code>	If enabled, the user visibility message are be sent to the management server.
<code>wan-state</code>	If enabled, the WAN state information is to be sent to the management server.
<code>wids-event-info-enable</code>	If enabled, the controller sends messages about current IDS events as soon as they are detected.
<code>source-ipv6-address <src-ipv6-addr></code>	Configure the source IPv6 Address for AMON packets.

Example

The following command defines a primary AirWave Management server.

```
(host) [mynode] (config) #mgmt-server primary-server 192.0.2.10 profile
default-amp
```

mgmt-user

```
mgmt-user
  audit-period
  console-blocks
  localauth <username>
  ssh-pubkey
    client-cert <certname> <username>
    <role> [<rcp>]
  webui-cacert <certificate_name> [serial <number>] <username> <role> [<rcp>]
  <username> <rolename> <max-concurrent-session> [node <path>] <password> <old-
  password>
```

Description

This command configures an administrative user. You can configure client certificate authentication of WebUI or SSH management users (by default, only username/password is used). To configure certificate authentication for the WebUI or SSH, use the web-server mgmt-auth certificate or ssh mgmt-auth public-key commands, respectively.

- Use `webui-cacert <certificate name>` command if you want an external authentication server to derive the management user role. This is helpful if there are a large number of users who need to be authenticated.
- Use the `mgmt-user webui-cacert <certificate_name> serial <number> <username> <role>` if you want the authentication process to use previously configured certificate name and serial number to derive the user role.
- Use the `mgmt-user webui-cacert <certificate_name> serial <number> <username> <role> <rcp>` command if you want to configure an optional RCP for an ssh-pubkey user.
- Use the `mgmt-user <username> <rolename> node <path> <password>` to configure an authenticated user assigned to a role in the managed device.

Parameter	Description
<code>audit-period</code>	Configures an audit period.
<code>console-blocks</code>	Blocks serial console access once the user logs out.
<code>localauth <username></code>	Enables the authentication of management users based on the results returned by the authentication server. To disable this setting, use the <code>no mgmt-user localauth</code> command. To verify if authentication of local management user accounts is enabled or disabled, use the following command: <code>show mgmt-user local-authentication-mode</code>

Parameter	Description
ssh-pubkey	Configures certificate authentication of administrative users using the CLI through SSH.
client-cert	Displays the name of the X.509 client certificate for authenticating administrative users using SSH.
<username>	Displays the name of the user.
<role>	Displays the role assigned to the authenticated user.
<rcp>	Revocation Checkpoint for the ssh user's client certificate. The rcp checks the revocation status of the SSH user's client certificate before permitting access.
webui-cacert	The client certificate for authenticating administrative users using the WebUI.
<certificate_name>	Displays the name of the CA certificate. If configured, certificate authentication and authorization are automatically completed using an authentication server.
serial	Displays the serial number of the client certificate.
<username>	Displays the name of the user.
<role>	Displays the role assigned to the authenticated user.
<rcp>	Revocation Checkpoint for the ssh user's client certificate. The rcp checks the revocation status of the SSH user's client certificate before permitting access.
<username>	<p>Displays the name of the user.</p> <p>You can create a maximum of 10 management users. Starting from ArubaOS 8.10.0.0, the username can have a maximum of 128 characters.</p> <p>NOTE: If you configure a root management user, you can use special characters except for double-byte characters.</p>
<rolename>	<p>Role assigned to the user. Predefined roles include:</p> <ul style="list-style-type: none"> ▪ guest-provisioning: Allows the user to create guest accounts on a special WebUI page. ▪ location-api-mgmt: Permits access to location API information. You can log into the CLI; however, you cannot use any CLI commands. ▪ network-operations: Permits access to Monitoring, Reports, and Events pages in the WebUI. You can log into the CLI; however, you can only use a subset of CLI commands to monitor the controller.

Parameter	Description
	<ul style="list-style-type: none"> read-only: Permits access to CLI show commands or WebUI monitoring pages only. root: Permits access to all management functions on the controller. standard: This role has root privileges but cannot make changes to the management users.
max-concurrent-sessions	Configures the maximum concurrent session for a management user. The maximum number of sessions allowed are 10.
node	Configures node level permissions. Use this parameter when you want to configure an authenticated user assigned to a role in the managed device.
<path>	Path of the managed device.
<password>	<p>NOTE: You are prompted for the <password> for this user after you type in <role> and press Enter.</p> <p>The password must have a minimum of six characters. Starting from ArubaOS 8.10.0.0, the password can have a maximum of 128 characters. Starting from ArubaOS 8.10.0.0, the password can have a maximum of 128 characters. You can use special characters in the management user password. The restrictions are as follows:</p> <ul style="list-style-type: none"> You cannot use double-byte characters You cannot use the question mark (?) You cannot use white space <space >
<old-password>	Provides the old password, to enable the user to change the management user password.

Example

The following command configures a management user and role:

```
(host)[node](config) #mgmt-user testuser1 root
Password: *****
Re-Type password: *****
```

mobility-manager

```
mobility-manager <A.B.C.D>  
  user <word> <string>  
    auth-prot {md5 | sha} <string>  
      priv-prot {AES | DES} <string>  
    interval <secs>  
    retrycount <count>  
    rtls <rtls-portnumber>  
    trap-version {1 | 2c | 3}  
    udp-port <portnumber>
```

Description

Use the command to allow a managed device to communicate with a mobility manager server (MMS). To configure a username and password for the managed device to communicate with MMS, execute the following command:

```
(host) [mm] (config) #mobility-manager 1.1.1.1 user testUN1 testUN1
```

The interval time, retry count, RTLS port number, and UDP port number are optional parameters that can be configured using the `mobility-manager` command.

If you try to configure a third mobility manager server, the following message is displayed:
Maximum number of 2 MMS servers already configured.

Parameter	Description
<A.B.C.D>	Configures the IP address of the mobility manager server for the managed device to communicate with.
user <word> <string>	Configures the username and password to communicate with MMS. Username: string of length 1-31, Password: string of length 1-31
auth-prot {md5 sha} <string>	Configures authentication protocol of the user with password. <ul style="list-style-type: none">■ md5: HMAC-MD5-96 Digest Authentication Protocol■ sha: HMAC-SHA-96 Digest Authentication Protocol■ <string> : Authentication Password 8-31 bytes
priv-prot {AES DES} <string>	Configures the privacy protocol of the user with password. <ul style="list-style-type: none">■ AES: CFB128-AES-128 Symmetric Encryption Protocol■ DES: CBC-DES Symmetric Encryption

Parameter	Description
	Protocol <ul style="list-style-type: none"> ■ <string> : Authentication Password 8-31 bytes
interval <secs>	Configures the time it takes for a UDP packet to travel to and from the trap server (round-trip time). This value indicates the timeout. 0-65535
retrycount <count>	Configures the maximum number of retries allowed to authenticate with MMS. 0-256
rtls <rtls-portnumber>	Configures the UDP port number for RTLS data collection. string of length 1-256 8000
trap-version {1 2c 3}	Configures trap server's SNMP version. 1, 2c, or 3
udp-port <portnumber>	Configures trap server's UDP port number. 1-65535 162

Example

The following command is an example to configure MMS and allow a managed device to communicate with it:

```
(host) [mm] (config) #mobility-manager 1.1.1.1 user testUN1 testUN1 auth-prot md5 authpswd interval 250
```

  mesh key-mac <dev-key>
  radio key-mac <dev-key>
  sta key-mac <dev-key>
  vap key-mac <dev-key>
  wan key-mac <dev-key>
```

Description

This command is used to enable or disable debug logs.

Parameter	Description
enable	Enable debugging.
disable	Disable debugging.
all-devices	Debugging of all device logs.
ap	Debugging of AP device logs.
mesh	Debugging of mesh AP device logs.
radio	Debugging of radio device logs.
sta	Debugging of station device logs.
vap	Debugging of VAP device logs.
wan	Debugging of WAN dashboard related device logs.
key-mac <dev-key>	Specify MAC address of the device.

Example

The example below enables debugging for the AP with MAC address 11.22.33.44.55.66.

```
(host) [mynode] (config) ##mon-serv-debug enable ap key-mac
11.22.33.44.55.66

netdestination

```
netdestination <dstname>
  description <description6>
  host <ipaddr> {vlan <vlanID> | offset <offset No>}
  invert
  name <host_name>
  network <ipaddr> <netmask>
  no ...
  range <start-ipaddr> <end-ipaddr>
```

Description

This command configures an alias for an IPv4 network host, subnetwork, or range of addresses. Aliases can simplify configuration of session ACLs, as you can use an alias when specifying the traffic source and/or destination in multiple session ACLs. Once you configure an alias, you can use it to manage network and host destinations from a central configuration point, because all policies that reference the alias will be updated automatically when you change the alias.

To create a local net destination override, use the **host vlan offset** option.

For example:

```
netdestination store
host vlan 10 offset 5
host vlan 10 offset 8
```

The subnets to a particular VLAN can be assigned by the bulk edit tool. With the above, user can pick whatever the subnet (for example 10.1.1.0/24) assigned to vlan 10 for that store and calculate offsets 5 (10.1.1.5) and 8 (10.1.1.8) from it.

When using the **invert** option, use caution when defining multiple aliases, as entries are processed one at a time. As an example, consider a netdestination configured with the following two network hosts:

```
netdestination dest1
invert
network 1.0.0.0 255.0.0.0
network 2.0.0.0 255.0.0.0
```

A frame from http://1.0.0.1 would match the first alias entry, (which allows everything except for 1.0.0.0/8) so the frame would be rejected. However, it would then be compared against the second alias, which allows everything except for 2.0.0.0/8, and the frame would be permitted.

Parameter	Description
<dstname>	Name for this host or domain. Maximum length is 63 characters.
description	Description about the this destination up to 128 characters long.

Parameter	Description
host	Configures a single IPv4 host.
A.B.C.D	Specify IPv4 address of the host.
vlan <1-4094>	Specify IPv4 address based on VLAN.
offset <1-254>	Specify offset in the VLAN subnet.
invert	Specifies that the inverse of the network addresses configured are used. For example, if a network of 172.16.0.0 255.255.0.0 is configured, this parameter specifies that the alias matches everything except this subnetwork.
name	<p>Use the <code>name</code> parameter to specify a domain or host name inside the <code>netdestination</code> object. Wildcards are supported through the asterisk (*) symbol, with the limitations described in the examples below.</p> <ul style="list-style-type: none"> ■ A wildcard '*' is allowed only once and only in the beginning of the host or domain name. (For instance, *.example.com is allowed, but example*.com and *example*.com are not allowed.) ■ If the wildcard is applied to the host, the <code>netdestination</code> matches all hosts ending with that specific domain. (The name *.example.com matches all hosts ending with the domain .example.com, such as demo.example.com.) ■ If the wildcard is applied to the domain, the <code>netdestination</code> matches all hosts ending with that domain string. (The name *example.com matches all domains ending with example.com, such as myexample.com and domainexample.com.)
network	An IPv4 subnetwork consisting of an IP address and netmask.
no	Negates any configured parameter.
range	A range of IPv4 addresses consisting of sequential addresses between a lower and an upper value. The maximum number of addresses in the range is 16. If larger ranges are needed, convert the range into a subnetwork and use the <code>network</code> parameter.

Example

The following command configures an alias for an internal network:

```
(host)[node](config) #netdestination Internal
(host)[node](config-dest) #network 10.1.0.0 255.255.0.0
```

The following command overrides the local network destination:

```
(host)[node](config)#netdestination store
(host)[node](config-dest)#host vlan 55 offset 36
```

Command History

netdestination6

```
netdestination6 <dstname>
  description <description6>
  host <ipaddr>
  invert
  name <host_name>
  network <ipaddr> <netmask>
  no ...
  range <start-ipaddr> <end-ipaddr>
```

Description

This command configures an alias for an IPv6 network host, subnetwork, or range of addresses. Aliases can simplify configuration of session ACLs, as you can use an alias when specifying the traffic source and/or destination. Once you configure an alias, you can use it in multiple session ACLs.

When using the **invert** option, use caution when defining multiple aliases, as entries are processed one at a time. As an example, consider a netdestination configured with the following two network hosts:

```
netdestination6 dest1 invert
network 2002:0:0:0:0:0:100:0/128
network 2002:0:0:0:0:0:200:0/128
```

A frame from http://1.0.0.1 would match the first alias entry, (which allows everything except for 2002:0:0:0:0:0:100:0/128) so the frame would be rejected. However, it would then be compared against the second alias, which allows everything except for 2002:0:0:0:0:0:200:0/128, and the frame would be permitted.

Parameter	Description
<dstname>	Name of the IPv6 destination host or subnetwork up to 63 characters long.
description	Description about the IPv6 netdestination up to 128 characters long.
host	Configures a single IPv6 host.
invert	Specifies that the inverse of the network addresses configured are used. For example, if a network of fe80:0:0:0:0:0:ac10:0/128 is configured, this parameter specifies that the alias matches everything except this subnetwork.
name	Use the <code>name</code> parameter to specify a domain or host name inside the netdestination object. Wildcards are supported through the asterisk (*) symbol, with the limitations described in the examples below.

Parameter	Description
	<ul style="list-style-type: none"> ■ A wildcard '*' is allowed only once and only in the beginning of the host or domain name. (For instance, *.example.com is allowed, but example*.com and *example*.com are not allowed). ■ If the wildcard is applied to the host, the netdestination matches all hosts ending with that specific domain. (The name *.example.com matches all hosts ending with the domain .example.com, such as demo.example.com). ■ If the wildcard is applied to the domain, the netdestination matches all hosts ending with that domain string. (The name *example.com matches all domains ending with example.com, such as myexample.com and domainexample.com).
network	An IPv6 subnetwork consisting of an IP address and netmask.
no	Negates any configured parameter.
range	A range of IPv6 addresses consisting of sequential addresses between a lower and an upper value. The maximum number of addresses in the range is 16. If larger ranges are needed, convert the range into a sub-network and use the <code>network</code> parameter.

Example

The following command configures an alias for an internal network:

```
(host) [mynode] (config) #netdestination6 Internal
(host) [mynode] (config-submode) #network fe80:0:0:0:0:a01:0/128
```

The following example displays the use of extended scope of address range:

```
(host) [mynode] (config) #netdestination6 ipv6-reserved-range
(host) [mynode] (config-submode) #invert
(host) [mynode] (config-submode) #network 2000::/3
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

netexthdr

```
netexthdr <name>  
  eh <eh-type> deny | permit
```

Description

This command allows you to edit the packet filter options in the extension header (EH). ArubaOS firewall is enhanced to process the IPv6 extension header (EH) to enable IPv6 packet filtering. You can filter the incoming IPv6 packets based on the EH type. You can edit the packet filter options in the default EH, using this command. By default, the default EH alias permits all EH types.

Parameter	Description
<name>	Specify the EH alias name.
eh <eh-type>	Specify one of the following EH types: <ul style="list-style-type: none">▪ <0-255>: Matches the IPv6 next header type▪ authentication: Matches the IPv6 authentication header▪ dest-option: Matches the IPv6 destination-option header▪ esp: Matches the IPv6 encapsulation security payload header▪ fragment: Matches the IPv6 fragment header▪ hop-by-hop: Matches the IPv6 hop-by-hop header▪ mobility: Matches the IPv6 mobility header▪ routing: Matches the IPv6 routing header
deny	Denies the IPv6 packets matching the specified extended header type.
permit	Permits the IPv6 packets matching the specified extended header type. NOTE: By default, all the EH types are supported in the default EH.

Example

The following command denies the IPv6 packets matching the specified extended header type in the default EH:

```
(host) [node] (config) #netexthdr default  
(host) [node] (config-exthdr) #eh authentication deny
```

Related Commands

net service

```
net service <name> <protocol>|tcp|udp {list <port>,<port>}|<port> [<port>]}  
[ALG <service> | http-proxy | https-proxy]
```

Description

This command configures an alias for network protocols. Aliases can simplify configuration of session ACLs, as you can use an alias when specifying the network service. Once you configure an alias, you can use it in multiple session ACLs.

Parameter	Description
net service	Name for this alias.
<protocol>	IP protocol number. 0-255
tcp	Configure an alias for a TCP protocol
udp	Configure an alias for a UDP protocol
list <port>,<port>	Specify a list of non-contiguous port numbers, by entering up to six port numbers, separated by commas. 0-65535
<port> [<port>]	TCP or UDP port number. You can specify a single port number, or define a port range by specifying both the lower and upper port numbers. 0-65535
ALG	Application-level gateway (ALG) for this alias.
<service>	Specify one of the following service types: <ul style="list-style-type: none">▪ dhcp: Service is DHCP▪ dns: Service is DNS▪ facetime: Service is Facetime▪ ftp: Service is FTP▪ h323: Service is H323▪ jabber: Service for Jabber▪ noe: Service is Alcatel NOE▪ rtsp: Service is RTSP▪ sccp: Service is SCCP▪ sip: Service is SIP▪ sips: Service is Secure SIP▪ svp: Service is SVP▪ tftp: Service is TFTP

Parameter	Description
	<ul style="list-style-type: none"> ▪ vocera: Service is VOCERA
http-proxy	HTTP proxy port.
https-proxy	HTTPS proxy port.

Example

The following command configures an alias for a network service:

```
(host)[mynode](config) #netSERVICE HTTP tcp 80
```

```

Description

This command allows you to configure NTP options. Network Time Protocol (NTP) authentication enables the controller to authenticate the NTP server before synchronizing local time with server. This helps identify secure servers from fraudulent servers. This command has to be enabled for NTP authentication to work.

Starting from 8.1.0.0, you can specify the source address for NTP traffic originating from the Mobility Conductor using the `source` parameter. Before this enhancement, the NTP traffic's source address was dynamically decided by the **NTP** module. The source of the NTP client traffic can be either a loopback interface or a specific VLAN ID. To allow time synchronization to be independent of any physical interfaces that could be down, use the loop back interface as the NTP source address.

Syntax

Parameter	Description
<code>authenticate</code>	This parameter enables the controller to authenticate the NTP server before synchronizing local time with server. This helps identify secure servers from fraudulent servers. This command has to be enabled for NTP authentication to work.
<code>authentication-key</code>	This command configures a key identifier and secret key and adds them into the database. NTP authentication works with a symmetric key configured by user. The key is shared by the client (Aruba managed device) and an external NTP server.
<code><key-id></code>	The key identifier is a string that is shared by the client (Arubamanaged device) and an external NTP server. This value is added into the database.
<code>md5 sha1 <keyvalue></code>	The key value is a secret string, which along with the key identifier, is used for authentication. This is added into the database.

Parameter	Description
debug	Enable NTP debug.
server	This command configures an NTP server. You can configure the Mobility Conductor to set its system clock using NTP by specifying one or more NTP servers.
<ip>/<ip6>/<fqdn>	IPv4/IPv6/FQDN address of the peer.
iburst	(Optional) This parameter causes the Mobility Conductor to send up to ten queries within the first minute to the NTP server. This option is considered "aggressive" by some public NTP servers. disabled
key <key-id>	This is the key identifier used to authenticate the NTP server. This needs to match the key identifier configured in the <code>ntp authentication-key</code> command.
server-mode [disable]	This command disables NTP server mode.
source	This command specifies the source address for NTP client traffic.
loopback	This parameter sets loopback interface as the source for NTP client traffic.
<vlanid>	This parameter sets source VLAN for NTP client traffic.
standalone	This command configures NTP time serve.
vlan-range <word>	Configures VLAN interfaces on which NTP adheres for serving time where: <word>: Represents VLAN range.
trusted-key	This command configures an additional subset of trusted keys which can be used for NTP authentication.
<keyid>	An additional trusted string that can be used for authentication.

Example

The following command configures an NTP server:

```
(host) [mynode] (config) #ntp authenticate
```

The following command configures the loopback interface as the source for NTP client traffic:

```
(host) [mynode] (config) #ntp source loopback
```

ntp authentication-key

```
ntp authentication-key <key-id>
  md5
  sha1
  <keyvalue>
```

Description

This command configures a key identifier and secret key and adds them into the database. NTP authentication works with a symmetric key configured by user. The key is shared by the client (Aruba controller) and an external NTP server.

NTP authentication works with a symmetric key configured by user. The key is shared by the client (Arubacontroller) and an external NTP server. This command adds both the key identifier and secret string into the database.

Parameter	Description	Range	Default
<key-id>	The key identifier is a string that is shared by the client (Aruba controller) and an external NTP server. This value is added into the database.	1-65534	—
md5 sha1	The hash algorithm type—use either md5 or sha1.	—	—
<keyvalue>	The key value is a secret string, which along with the key identifier, is used for authentication. This is added into the database.	0-255 ASCII characters	—

Example

The following command configures the NTP authentication key. For the MD5 hash algorithm, the key identifier is 12345 and the shared secret is 67890.

```
(host) [mynode] (config) #ntp authentication-key 12345 md5 67890
```

The following example shows NTP authentication key configuration using SHA1 hash algorithm:

```
(host) [mynode] (config) #ntp authentication-key 41 sha1 secretkey
```

Command History

Release	Modification
ArubaOS 8.2.1.0	The <code>sha1</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

openflow-controller

```
openflow-controller
  auxiliary-channel-port <port>
  host-ageout-time <value>
  mode passive
  no
  openflow-controller-enable
  port <port>
  tls-ca-cert-file <tls-ca-cert-file>
  tls-certificate-file <tls-certificate-file>
  tls-enable
  tls-key-file <tls-key-file>
  topology-discovery-enable
```

Description

This command configures OpenFlow controller on Mobility Conductor. The OpenFlow controller must be configured from the **/mm** node hierarchy of Mobility Conductor. OpenFlow controller is disabled by default. For OpenFlow to be functional in a network, you must enable OpenFlow controller on the Mobility Conductor and OpenFlow agent on the required managed devices. By default, OpenFlow is disabled on Mobility Conductor as well as the managed devices.

Parameter	Description
auxiliary-channel-port	Configures a listening port for OpenFlow controller in the auxiliary channel (UDP) to send and receive packets without consuming bandwidth on the main channel.
host-ageout-time	Configures the ageout time for the host.
mode {passive}	Sets the OpenFlow controller mode. This release of ArubaOS provides support only for passive mode. passive passive
no	Negates any configuration.
openflow-controller-enable	Enables or disables OpenFlow controller on Mobility Conductor disabled
port	The listening port for the OpenFlow controller. 1-65535 6633

Parameter	Description
tls-ca-cert-file	Configures the CA certificate file from the specified path.
tls-certificate-file	Configures the certificate file from the specified path.
tls-enable	Enables or disables TLS. disabled
tls-key-file	Configures the key from the specified path
topology-discovery-enable	Enables the Openflow controller topology. disabled

Examples

The following commands enables OpenFlow controller on Mobility Conductor:

```
(host) [mm] (config) #openflow-controller
(host) [mm] (openflow-controller) #openflow-controller-enable
```

Related Commands

  custom-cert-enable
  mode passive
  no
  openflow-auxiliary-enable
  openflow-enable
  tls-ca-cert-file <tls-ca-cert-file>
  tls-certificate-file <tls-certificate-file>
  tls-enable
  tls-key-file <tls-key-file>
  version {v1.0|v1.3}
```

Description

This command configures OpenFlow profile on the managed device. The OpenFlow profile must be configured from the **/md** node hierarchy of Mobility Conductor. OpenFlow profile is disabled by default. For OpenFlow to be functional in a network, you must enable OpenFlow controller on the Mobility Conductor and OpenFlow agent on the required managed devices. By default, OpenFlow is disabled on Mobility Conductor as well as the managed devices.

Parameter	Description
auxiliary-channel-port <port>	Configures a listening port for OpenFlow Controller in the auxiliary channel (UDP) to send and receive packets without consuming bandwidth on the main channel.
bind-vlan [add remove] <vlan>	Configures a specified range of OpenFlow VLANs. You can optionally add or remove the specified VLANs or VLAN range from the configured list of VLANs.
controller-ip <port>	Configures the IP and listening port of the OpenFlow Controller running on Mobility Conductor. 1-65535 6633
custom-cert-enable	Enable or disable non-TPM custom certificate. Disabled
mode {passive}	Sets the OpenFlow agent mode.

Parameter	Description
	This release of ArubaOS provides support only for passive mode. passive passive
no	Negates any configuration.
openflow-auxiliary-enable	Enables or disables OpenFlow auxiliary channel. disabled
openflow-enable	Enables or disables OpenFlow agent on the managed device. disabled
tls-ca-cert-file <tls-ca-cert-file>	Configures the CA certificate file from the specified path.
tls-certificate-file <tls-certificate-file>	Configures the certificate file from the specified path.
tls-enable	Enables or disables TLS. disabled
tls-key-file <tls-key-file>	Configures the key from the specified path
version {v1.0 v1.3}	Configures the OpenFlow version. v1.3

Examples

Execute the following commands to configure and enable the OpenFlow profile:

```
(host) [md] (config) #openflow-profile
(host) [md] (Openflow-profile) #openflow-enable
(host) [md] (Openflow-profile) #controller-ip <master/ conductor -ip> <port>
```

packet-capture

```
packet-capture
  controlpath
  copy-to-flash {controlpath-pcap | datapath-pcap}
  datapath {ipsec <peer-ip>|<peer-ipv6>} [wifi-client <mac-address> {decrypted |
  encrypted | all}]
  destination [interface <slot/module/port>] [ip-address <ip-address>] [local-
  filesystem]
  no
  reset-pcap {controlpath-pcap | datapath-pcap}
```

Description

This command enables or disables packet capturing and set packet capturing options for a single packet capture session.

Parameter	Description
controlpath	Enables controlpath packet capture. Captured packets are stored in /var/log/oslog/filter.pcap. NOTE: Only capture to local-filesystem is supported for controlpath capture. Disabled
interprocess	Enables or disables interprocess packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all ports. All CLI ports, which are TCP, are always skipped. Disabled
other	Enable or disable all other types of packets. Disabled
sysmsg	Enable or disable internal messaging packets. Specify up to ten comma-separated opcodes to capture; use <code>all</code> to sniff all opcodes. All CLI ports, which are TCP, are always skipped. Disabled
tcp	Enable or disable TCP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all TCP ports. All CLI ports, which are TCP, are always skipped. Disabled

Parameter	Description
udp	Enable or disable UDP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all UDP ports. All CLI ports, which are TCP, are always skipped. Disabled
copy-to-flash	Copies captured packets to the flash.
controlpath-pcap	Copies controlpath captures. They are saved as controlpath-pcap.tar.gz .
datapath-pcap	Copies datapath captures. They are saved as datapath-pcap.tar.gz .
datapath	Enables datapath packet capture. Captured packets are stored in <code>/var/log/oslog/datapath.pcap</code> or mirrored out of the managed device. Disabled
ipsec <peer-ip>	Enable or disable IPsec packet capturing. Enter the IPsec peer IP address to specify a given peer. NOTE: Capture to local-filesystem is not supported with this option. Disabled
ipsec <peer-ipv6>	Enable or disable IPsec packet capturing. Enter the IPsec peer IPv6 address to specify a given peer. NOTE: Capture to local-filesystem is not supported with this option. Disabled
wifi-client <mac-address> {decrypted encrypted all}	Enable or disable packet capturing from a wifi client. Specify the client device by entering the device's MAC address. Additionally, you can specify what type of traffic captured: decrypted, encrypted, or all. Disabled
destination	Configures the capture destination.
interface <slot/module/port>	Interface in <slot>/<module>/<port> format.
ip-address <ip-address>	Sends packet captures to a specific IP address.
local-filesystem	Stores captured packets on the managed device in pcap files.

Parameter	Description
no	Negates any configured parameter.
reset-pcap	Deletes old pcap files and restarts the active capture.
controlpath-pcap	Deletes old controlpath pcap files and restarts the active controlpath capture.
datapath-pcap	Deletes old datapath pcap files and restarts the active datapath capture.

This command can perform two types of packet capture: controlpath and datapath. Controlpath only captures packet destined for the managed device. Datapath captures packets that are being forwarded by the managed device, such as packets from a wifi client.

Packets can be retrieved through the `tar logs` command; look for the `filter.pcap` or `datapath.pcap` file. This command activates packet capture options on the current session. They are not saved and applied across all reboots.

Related Command

Command	Description
show papi-security	<p>Defines a set of default packet capture options on the control path and saves them in the configuration file. These settings are automatically enabled when the managed device boots up.</p> <p>NOTE: Any settings defined using the packet-capture command overrides packet-capture-defaults.</p>

Example

The following example enables packet capturing for debugging a wireless WEP station doing VPN. This example uses the following parameters and values:

- Station up/down: sysmsg opcode 30
- WEP key plumbing: sysmsg opcode 29
- DHCP: sysmsg opcode 90
- IKE: UDP port 500 and 4500
- Layer 2 Tunneling Protocol (L2TP): UDP port 1701

```
(host) [/md] (config) #packet-capture sysmsg 30,29,90
(host) [/md] (config) #packet-capture udp 500,4500,1701,1812,1645
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

packet-capture-defaults

```
packet-capture
  controlpath [interprocess {all | <ports>}] [other] [sysmsg {all | <opcodes>}
  [tcp {all | <ports>}] [udp {all | <ports>}]
  datapath {ipsec <peer-ip>} [wifi-client <mac-address> {decrypted | encrypted |
  all}]
  destination [interface <slot/module/port>] [ip-address <ip-address>] [local-
  filesystem]
  no
```

Description

Use this command to enable or disable packet capturing and define a set of default packet capturing options on the control path for debugging purposes.

This command applies to control path packets; not datapath packets. Packets can be retrieved through the `tar log` command; look for the `filter.pcap` file. This command activates packet capture options on the current switch. They are not saved and applied across switches.

Parameter	Description
controlpath	Enables controlpath packet capture. Captured packets are stored in <code>/var/log/oslog/filter.pcap</code> . Only capture to local-filesystem is supported for controlpath capture. Disabled
interprocess	Enables or disables interprocess packet capturing. . Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all ports. All CLI ports, which are TCP, are always skipped. Disabled
other	Enable or disable all other types of packets. Disabled
sysmsg	Enable or disable internal messaging packets. Specify up to ten comma-separated opcodes to capture; use <code>all</code> to sniff all opcodes. All CLI ports, which are TCP, are always skipped. Disabled
tcp	Enable or disable TCP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all TCP ports. All CLI ports, which are TCP, are always skipped. Disabled

Parameter	Description
udp	Enable or disable UDP packet capturing. Specify up to ten comma-separated ports to capture; use <code>all</code> to sniff all UDP ports. All CLI ports, which are TCP, are always skipped. Disabled
datapath	Enables datapath packet capture. Captured packets are stored in <code>/var/log/oslog/datapath.pcap</code> or mirrored out of the controller. Disabled
ipsec <peer-ip>	Enable or disable IPsec packet capturing. Enter the IPsec peer IP address to specify a given peer. NOTE: Capture to local-filesystem is not supported with this option. Disabled
wifi-client <mac-address> {decrypted encrypted all}	Enable or disable packet capturing from a wifi client. Specify the client device by entering the device's MAC address. Additionally, you can specify what type of traffic captured: decrypted, encrypted, or all. Disabled
destination	Configures the capture destination.
interface <slot/module/port>	Interface in <slot>/<module>/<port> format.
ip-address <ip-address>	Sends packet captures to a specific IP address.
local-filesystem	Stores captured packets on the controller in pcap files.
no	Negates any configured parameter.

Example

The following example sets the default packet capture values to debug a wireless WEP station doing VPN. Once these default settings are defined, you can use the [packet-capture](#) command to enable packet capturing with these values. This example uses the following parameters and values:

- Station up/down: `sysmsg opcode 30`
- WEP key plumbing: `sysmsg opcode 29`
- DHCP: `sysmsg opcode 90`

- IKE: UDP port 500 and 4500
- Layer 2 Tunneling Protocol (L2TP): UDP port 1701

```
(host) [mynode] (config)#packet-capture-defaults sysmsg 30,29,90 udp
500,4500,1701,1812,1645
```

Use the show packet-capture command to show the current action and the default values.

```
(host) [mynode] (config)#show packet-capture

Current Active Packet Capture Actions(current switch)
=====
Packet filtering TCP with 2 port(s) enabled:
  2
  1
Packet filtering UDP with 1 port(s) enabled:
  1
Packet filtering for internal messaging opcodes disabled.
Packet filtering for all other packets disabled.

Packet Capture Defaults(across switches and reboots if saved)
=====
Packet filtering TCP with 2 port(s) enabled:
  2
  1
Packet filtering UDP with 1 port(s) enabled:
  1
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command Introduced.

Command Information

Platforms	License	Command Mode

page

page <length>

Description

This command sets the number of lines of text the terminal will display when paging is enabled. Use this command in conjunction with the `paging` command to specify the number of lines of text to display. For more information on the pause mechanism that stops the command output from printing continuously to the terminal, see [paging on page 1069](#).

If you need to adjust the screen size, use your terminal application to do so.

Parameter	Description
length	Specifies the number of lines of text displayed. 24 - 100

Example

The following example sets 80 as the number of lines of text displayed:

```
(host) [mynode] (config) #page 80
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Configuration mode on Mobility Conductor.

paging

paging

Description

This command stops the command output from printing continuously to the terminal. By default, this command is enabled.

With paging enabled, there is a pause mechanism that stops the command output from printing continuously to the terminal.

If paging is disabled, the output prints continuously to the terminal. To disable paging, use the `no paging` command. You must be in enable mode to disable paging.

The paging setting is active on a per-user session. For example, if you disable paging from the CLI, it only affects that session. For new or existing sessions, paging is enabled by default.

You can also configure the number of lines of text displayed when paging is enabled. For more information, see [page on page 1068](#).

If you need to adjust the screen size, use your terminal application to do so.

Example

The following example enables paging:

```
(host) [mynode] (config) #paging
```

pan active-profile

```
pan active-profile  
  profile <profile name>
```

Description

This command makes a Palo Alto Network (PAN) profile active from a set of profiles. Only one PAN profile can be active at a time.

Parameter	Description
profile <profile name>	The name of the PAN profile to be activated.

Example

The following example creates an active PAN profile from a set of profiles.

```
(host) [mynode] (config) #pan active-profile  
(host) [mynode] (Palo Alto Networks Active Profile) #profile default
```

pan profile

```
pan profile <profile-name>
  clone
  firewall host <host> port <port> username <username> passwd <password>
  no
```

Description

This command configures a Palo Alto Networks profile to allow a managed device to communicate with a PAN firewall. This command is used to configure the PAN firewall that the managed device will be communicating with. The username and password must match the name of the admin account configured on the PAN firewall.

Parameter	Description
clone	Name of an existing PAN profile configuration from which parameter values are copied.
firewall	Configures the information for the associated PAN firewall.
host <host>	IP address or hostname of the PAN firewall.
port <port>	Port number of the PAN firewall.
username <username>	The username of the PAN firewall.
passwd <password>	The password of the PAN firewall.
no	Negates any configured parameter.

Example

The following example configures a Palo Alto Networks profile to allow a managed device to communicate with a PAN firewall.

```
(host) [mynode] (config) #pan profile default
(host) [mynode] (Palo Alto Networks Servers Profile "default") #firewall
host 192.0.2.1 port 5642 username axde passwd ZAQ!2wsx
```

panic

```
panic {clear | info {file <filename> <symbolfile>|nvram <symbolfile>} | list {file <filename>|nvram} | save <filename>}
```

Description

This command manages information created during a system crash. To troubleshoot system crashes, use the `panic save` command to save information from NVRAM into the specified file, then use the `panic clear` command to clear the information from NVRAM.

Parameter	Description
<code>clear</code>	Removes panic information from non-volatile random access memory (NVRAM).
<code>info</code>	Displays the content of specified panic files.
<code>list</code>	Lists panic information in the specified file in flash or in NVRAM.
<code>save</code>	Saves panic information from NVRAM into the specified file in flash.

Example

The following example lists panic information in NVRAM:

```
(host) [mynode] #panic list nvram
```

Command History

papi-security

```
papi-security {enhanced-security|key <key>}  
no
```

Description

This command enforces advanced security options and provides an enhanced level of security. It allows to enable or disable the PAPI Enhanced Security configuration and to configure a new security key, if required.

Parameter	Description
Enhanced-security	Enables PAPI Enhanced Security Disable
Key <key>	Secret key that is used to authenticate messages between systems 10-64 characters
no	Disables the earlier configuration

This command allows you to use advanced options that regulate PAPI communication between Mobility Conductor and managed devices. When enhanced security is enabled, PAPI messages are authenticated at the receiving device and are denied if validation failed.

Mismatch in secret key will affect centralized licensing and AirWave.

One of the ways PAPI messages are authenticated is through a shared secret key. The papi-security command lets you configure a key on the Mobility Conductor and the managed devices. If no key is configured, then the controller uses the default key.

The Mobility Conductor and the managed device must be configured with the same PAPI key.

Example

The following example enables the PAPI Enhanced Security mode:

```
(host)[mynode] (config) #papi-security  
(host)[mynode] (PAPI Security Profile) #enhanced-security
```

The following example configures a new PAPI Enhanced Security key for controllers and AirWave:

```
(host)[mynode] (PAPI Security Profile) #key 1234567890
```

Related Commands

Command	Description
show papi-security	Shows the status of the PAPI Enhanced Security configuration of the controller.
show ipc statistics app-id show ipc statistics app-name	Show the PAPI statistics for messages transmitted, received, signed, validated, denied, and more based on application ID or the application name.

password-recovery-disable

```
password-recovery-disable  
no ...
```

Description

This command disables the default password recovery feature in the controller. This command can be executed in SSH sessions and serial console sessions with the controller.

Parameter	Description
password-recovery-disable	Disables the default password recovery feature.
no	Enables the default password recovery feature.

Example

The following example shows how to disable the default password recovery user:

```
(host) configure terminal  
Enter Configuration commands, one per line. End with CNTL/Z  
(host) (config) #password-recovery-disable
```

The following example shows how to enable the default password recovery user:

```
(host) configure terminal  
Enter Configuration commands, one per line. End with CNTL/Z  
(host) (config) #no password-recovery-disable
```

Related Commands

Command	Description

password-recovery-user

```
password-recovery-user <username>  
no ...
```

Description

This command creates an alternate password recovery user and disables the default password recovery feature. This command can be executed in SSH sessions and serial console sessions with the controller.

Parameter	Description
<username>	User name for the password recovery user.
no	Deletes the configured password recovery user and enables the default password recovery feature.

Example

The following example shows how to configure the alternate password recovery user:

```
(host) #configure terminal  
Enter Configuration commands, one per line. End with CNTL/Z  
(host) (config) #password-recovery-user recadmin  
Password:*****  
Re-Type password:*****  
(host) (config) #exit
```

The following example shows how to delete the alternate password recovery user:

```
(host) configure terminal  
Enter Configuration commands, one per line. End with CNTL/Z  
(host) (config) #no password-recovery-user
```

perf-test server

```
perf-test server
  start
    ap {[ap-name <ap-name>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>] [tcp [window <window>]] | udp}
    controller {[tcp [window <window>]] | udp}
  stop
    ap {[ap-name <ap-name>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>] [tcp [window <window>]] | udp}
    controller {[tcp [window <window>]] | udp}
```

Description

This command launches Iperf throughput test.

Parameter	Description
start	Starts Iperf throughput tests in server mode
stop	Stops Iperf throughput tests in server mode
ap {[ap-name <ap-name>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>] [tcp [window <window>]] udp}	Starts Iperf throughput test on an AP using: [ap-name <ap-name>] : AP name [ip-addr <ip-addr>] : IP address of AP [ip6-addr <ip6-addr>] : IPv6 address of IP [tcp [window <window>]] : Use TCP window size with suffix k for kilo or m for mega udp : Use UDP
controller {[tcp [window <window>]] udp}	Starts Iperf throughput test on a controller using: [tcp [window <window>]] : Use TCP window size with suffix K for kilo or M for mega udp : Use UDP

Example

The following example starts Iperf throughput test on AP **test** using TCP window size 2k:

```
(host) [mynode] #perf-test server start ap ap-name test tcp window 2k
```

Command	Description
show perf-test reports	Use this command to view the results of an Iperf throughput test.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

perf-test client

```
perf-test client
  start
    ap {[ap-name <ap-name>]|[ip-addr <ip-addr>]|[ip6-addr <ip6-addr>]} [host
    {<ip>|<ip6>}] [duration <duration>] [parallel <parallel>] [tcp [window
    <window>]] [udp [bandwidth <bandwidth>]]
    controller [host {<ip>|<ip6>}] [duration <duration>] [parallel <parallel>]
    [tcp [window <window>]] [udp [bandwidth <bandwidth>]]
  stop
    ap {[ap-name <ap-name>] [ip-addr <ip-addr>] [ip6-addr <ip6-addr>]}
    controller
```

Description

This command launches lperf throughput test in client mode. This command launches or stops lperf throughput test in client mode.

Parameter	Description
start	Starts lperf throughput tests in client mode.
ap	Starts lperf throughput tests on specified AP in client mode.
ap-name <ap-name>	Specifies name of an AP.
ip-addr <ip-addr>	Specifies IP address of an AP.
ip6-addr <ip6-addr>	Specifies IPv6 address of an AP.
host {<ip> <ip6>}]	Specifies IP or IPv6 address of perf server.
duration <duration>	Specifies time, in seconds, to transmit. Default is 10 and range is 10 to 120.
parallel <parallel>	Specifies number of parallel clients threads to run. This should be less than the number of parallel threads on the server.
tcp [window <window>]	Specifies TCP window size to use.
udp [bandwidth <bandwidth>]]	Specifies UDP bandwidth to use.
controller	Starts lperf throughput tests on specified controller in client mode.
stop	Stops lperf throughput tests in client mode

Example

The following example starts lperf throughput test on an AP named **ap215** using TCP window size 2k in client mode:

```
(host) [mynode] #perf-test client start ap ap-name ap215 host 192.0.2.1
duration 10 parallel 1 tcp window 2
```

perf-test port

perf-test port {close|open}

Description

This command closes or opens lperf throughput test port 5001.

Parameter	Description
close	Closes lperf throughput test port 5001.
open	Opens lperf throughput test port 5001.

Example

The following example closes lperf throughput test port 5001:

```
(host) [mynode] #perf-test port close
```

phonehome

```
phonehome
  auto-report
  disable
  enable
  https <from_addr>
  now
  smtp <a.b.c.d> <from_addr> [port <port_num>] {size <max_size>} [user <username>
  pass <password>]
```

Description

This command configures the PhoneHome auto reporting feature. By default, the managed device sends PhoneHome reports to the Activate server using HTTPS. Most deployments should retain the default behavior send PhoneHome reports via Activate. However, if the managed device is behind proxy server and does not have direct access to Internet, PhoneHome should be configured to send reports using SMTP. The following section of this document describes the benefits of each of these configurations options.

Parameter	Description
auto-report	The managed device will periodically contact Aruba support once a week to report any errors or changes to the managed device configuration or inventory. If the managed device has not reported any errors and its configuration file has not changed, no report will be sent. NOTE: Before you enable auto-reporting, you must first enable the PhoneHome feature using the command <code>phonehome enable</code> .
disable	This parameter disables the PhoneHome feature. Phonehome automatic reporting is disabled by default.
enable	This parameter enables the PhoneHome feature.
now	Issue the <code>phonehome now</code> command in enable mode to immediately create and send a report from the managed device to Aruba support. NOTE: Before you use the <code>phonehome now</code> command to create and send a report, you must first access the CLI in config mode and issue the command <code>phonehome enable</code> to enable this feature.

Parameter	Description
https <from_addr>	Configure managed device to send PhoneHome reports to an Activate server using HTTPS. The <from-addr> email address is used to properly identify the user sending the report.
smtp	Configure the SMTP server that will send email messages from the managed device to Aruba support.
<a.b.c.d>	IP address of the SMTP server
<from_addr>	Local email address from which the auto reporting messages will be sent. For example, <i>admin@mycorp.com</i> .
port <port_num>	(Optional) Port number from which the SMTP server will send auto reporting emails. Default port number: 25.
size <max_size>	(Optional) If your SMTP server has a restriction on the size of the emails it can send, use this parameter to specify the maximum size limit. Any reports larger than this limit will be divided into multiple smaller emails.
user <username> pass <password>	(Optional) If your SMTP server requires user authentication before it can send an email message, enter the username and password for a valid user on your network.

Sending Phonehome Reports using Activate

PhoneHome integration with Activate offers following benefits:

- **Simpler configuration.** Phonehome only requires you to configure the email ID of the network administrator managing the device. as Activate already has information to accurately identify your managed device. If a DNS server is not configured on the managed device, PhoneHome will query the public DNS service (8.8.8.8) to resolve the Activate server IP address.
- **Smaller bandwidth requirements.** When the PhoneHome feature sends the report to the Activate server, the PhoneHome report is zipped into a smaller package, then divided into smaller 1MB pieces before being sent to the server using secure HTTPS. Only reports sent to Activate are zipped before they are sent, so reports sent to Activate use less bandwidth than a report sent to a SMTP server.
- **Enhanced error management.** If any individual portion of the report is not successfully received by the Activate server, PhoneHome makes up to three attempts to resend just that portion of the file, rather than resending the entire report. Reports sent via SMTP must be resent in their entirety if any portion is not received by the SMTP server.
- **Automatic removal of old reports.** Once the entire report has been sent to the Activate server, Activate sends an acknowledgment to the managed device, prompting the managed device to delete its local copy of the report.

Sending Reports using SMTP

If you configure the PhoneHome feature to use SMTP, the PhoneHome status reports is sent in an email. When the managed device generates the report email with the PhoneHome data file attachment, it forwards the email to the local SMTP server configured on your local network, which then relays the message to Aruba technical support. If your email server requires the sender to be authenticated before message delivery, the managed device can connect to the SMTP server by supplying the sender's user name and password.

When PhoneHome reports are sent using SMTP, the PhoneHome report attachment is encrypted before it is transmitted to the SMTP server, and is decrypted by Aruba support the report it is received. If the PhoneHome status report email is larger than the maximum email size supported by your SMTP server, the managed device divides the PhoneHome attachment into multiple smaller attachments and sends the report to Aruba in multiple emails. If any individual portion of the report is not successfully received by the SMTP server, PhoneHome resends the entire report.

Example

The following example turns on the PhoneHome feature, enables weekly auto-reports, and identifies the SMTP server to be used by this feature:

```
(host) [mynode] (config) #phonehome enable auto-report smtp 172.21.18.170
admin@mycorp.com
```

ping

ping

ipv6

```
<global-address> [count <count-value>] [df-flag-ipv6] [validate-reply]
[packet-size <size-value>] [interval <interval-value>] [pattern <pattern-
value>] [timeout <timeout-value>] [tos <tos-value>] [ttl <ttl-value>]
[validate-reply] [source [[<source-address>] [mgmt-interface]]]
interface [vlan <vlanid>] <linklocal-address>
<target> [count <count-value>] [df-flag] [validate-reply] [send-amon] [packet-
size <size-value>] [interval <interval-value>] [pattern <pattern-value>] [timeout
<timeout-value>] [tos <tos-value>] [ttl <ttl-value>] [validate-reply] [source
[[<source-address>] [mgmt-interface]]]
```

Description

This command sends ICMP echo packets to the specified IPv4 or IPv6 address.

Parameter	Description
ipv6	Ping specified IPv6 address.
<global-address>	Ping specified global IPv6 address
count <count-value>	Specifies the number of ping packets to send. 1-1000 5
df-flag-ipv6	Sets the do not fragment flag.
dscp <dscp-value>	Set 6 bits of DSCP field in IP header.
interval <interval-value>	Sets the time interval, in seconds, between ping datagrams. 1-60 seconds 1 second

Parameter	Description
<pre>packet-size <size-value></pre>	<p>Specifies the size in bytes of the ping datagram.</p> <p>10-2000 bytes 100 bytes</p>
<pre>pattern <pattern-value></pre>	<p>Specifies the hexadecimal digit pattern.</p> <p>Up to 16 digits</p>
<pre>source [[<source-address>][mgmt-interface]</pre>	<p>Specifies the source interface (management interface, or VLAN ID) for the ping datagram.</p> <p>1-4094</p>
<pre>sweep-range <min size> <max size> <sweep-interval></pre>	<p>The range of echo packets sizes to be varied while sending out echos.</p> <ul style="list-style-type: none"> ▪ min size : Start packet size in range 10 to 1999. ▪ max size : End packet size in range 11 to 2000. ▪ sweep-interval : Interval or spaces between the echoed packets in range 1 to 1990.
<pre>timeout <timeout-value></pre>	<p>Specifies the time, in seconds, to wait for response.</p>

Parameter	Description
	1-10 seconds 2 seconds
tos <tos-value>	Sets 8 bits of traffic class field in IPv6 header. 0-255 0
ttl <tll-value>	Sets the TTL value, in seconds, for the ping datagram. 1-255 seconds 225 seconds
validate-reply	Validates the reply data.
interface	Specifies interface for link-local address.
vlan <vlanid>	Specifies VLAN ID for local-link address.
<linklocal-address>	Specifies IPv6 link-local address.
<target>	Pings specified IP address

Examples

The following example pings 192.0.2.1.

```
(host) [mynode] #ping 192.0.2.1

Press 'q' to abort.
Sending 5, 92-byte ICMP Echos to 192.0.2.1, timeout is 2 seconds:
.....
Success rate is 100 percent (5/5), round-trip min/avg/max =
0.03/0.0312/0.036 ms
```

The following example pings the specified IPv6 global address:

```
(host) [mynode] #ping ipv6 2001:db8:0:abcd::1

Press 'q' to abort.
Sending 5, 92-byte ICMPv6 Echos to 2001:db8:0:abcd::1, timeout is 2 seconds:
.....
Success rate is 100 percent (5/5), round-trip min/avg/max =
0.03/0.0312/0.036 ms
```

Command History

[cp-dp-sp-message] [port] [ftp] [icmp-error] [wep-encrypt] [wep-decrypt] [ipsec-
encrypt] [ipsec-decrypt] [ipsec-ctrl] [pptp] [ip-re-assembly] [wep-icmpfr] [dhcp]
[mobility] [peer] [pptp-ctrl] [tkip-encrypt] [tkip-decrypt] [tkip-ctrl] [tkip-
alloc-err] [sip-alg] [skinny] [vocera] [gsi] [aesccm-encrypt] [aesccm-decrypt]
[netad] [xSec-ctrl] [xSec-encrypt] [xSec-decrypt] [tcp-termination] [log-2]
[dpi]]
```

Description

This command is used to trace packets in the datapath. Use this command only under the supervision of Aruba technical support.

Parameter	Description
<name>	Traces packets for the specified access-control list.
enable	Enables packet tracing for the ACL.
disable	Disables packet tracing for the ACL.
log	Writes packet trace data to log file.
tracemask <tmask>	Specify the trace mask. This value will be provided by Aruba technical support.
trace-hex-mask	Configures datapath trace mask in hexadecimal form
<tmask>	Specifies trace mask in hexadecimal form
[log-1]	Writes packet trace data to log file.
trace	Configures datapath trace options.
acl-processing	Trace mask for acl functionality
aesccm-decrypt	Trace mask for aesccm-decrypt functionality
aesccm-encrypt	Trace mask for aesccm-encrypt functionality
bridge	Trace mask for bridge functionality
bwm	Trace mask for bwm functionality

Parameter	Description
cp-dp-sp	Trace mask for control path, slow path and fast path messaging functionality
cp-dp-sp-message	Additional trace mask for control path, slow path and fast path messaging functionality
dhcp	Trace mask for dhcp functionality
dpi	Trace mask for datapath DPI
event	Trace mask for event functionality
fast	Trace mask for fast functionality
ftp	Trace mask for FTP functionality
gsi	Trace mask for GSI functionality
heap	Trace mask for heap functionality
icmp-error	Trace mask for ICMP error processing functionality
init	Trace mask for init functionality
ip-re-assembly	Trace mask for IP re-assembly functionality
ipsec-ctrl	Trace mask for IPsec-ctrl functionality
ipsec-decrypt	Trace mask for IPsec-decrypt functionality functionality
ipsec-encrypt	Trace mask for IPsec-encrypt functionality functionality
log-2	Enables writing packet trace data into log file
mcast	Trace mask for mcast functionality
mobility	Trace mask for mobility functionality
nat	Trace mask for NAT functionality
netad	Trace mask for netad functionality
peer	Trace mask for peer functionality
port	Trace mask for port functionality
pptp	Trace mask for PPTP functionality
pptp-ctrl	Trace mask for PPTP-ctrl functionality
recv	Trace mask for recv functionality

Parameter	Description
route	Trace mask for route functionality
rtsp	Trace mask for rtsp functionality
send	Trace mask for send functionality
session	Trace mask for session functionality
sip-alg	Trace mask for sip alg service functionality
skinny	Trace mask for skinny functionality
station	Trace mask for station functionality
tcp-termination	Trace mask for datapath TCP termination functionality
tkip-alloc-err	Trace mask for TKIP-alloc-err functionality
tkip-ctrl	Trace mask for TKIP-ctrl functionality
tkip-decrypt	Trace mask for TKIP-decrypt functionality
tkip-encrypt	Trace mask for TKIP-encrypt functionality
trunk	Trace mask for trunk functionality
tunnel	Trace mask for tunnel functionality
user	Trace mask for user functionality
vlan	Trace mask for VLAN functionality
vocera	Trace mask for Vocera functionality
wep-decrypt	Trace mask for WEP-decrypt functionality functionality
wep-encrypt	Trace mask for WEP-encrypt functionality functionality
wep-icmpfr	Trace mask for WEP-icmpfr functionality
xSec-ctrl	Trace mask for xSec-ctrl functionality
xSec-decrypt	Trace mask for xSec-decrypt functionality
xSec-encrypt	Trace mask for xSec-encrypt functionality

Example

The following example enables packet tracing for the traffic matching the acl **stateful-dot1x**.

```
(host) [mynode] #pkt-trace acl stateful-dot1x enable trace
```

Command History

pkt-trace-global

```
pkt-trace-global
  sbeth
    destination-ip
    destination-mac
    ether-type
    packet-count
    packet-stats
    protocol
    source-ip
    source-mac
    trace-type
  trace
  trace-hex-mask <tmask>
  tuple
    destination-ip
    destination-mac
    ether-type
    packet-count
    protocol
    source-ip
    source-mac
```

Description

This command enables global packet tracing in the datapath. Use this command only under the supervision of Aruba technical support.

Parameter	Description
sbeth	Configure datapath buffer tracing.
destination-ip	Specify the destination IP address (A.B.C.D).
destination-mac	Specify the destination MAC address (AA:BB:CC:DD:EE:FF).
ether-type	Specify the packet ethernet frame type.
packet-count	Specify the number of packets to trace.
packet-stats	Per flow Frame statistics.
protocol	Specify protocol number.
source-ip	Specify source IP address (A.B.C.D).

Parameter	Description
source-mac	Specify source MAC address (AA:BB:CC:DD:EE:FF).
trace-type <1-3>	Specify type of the trace to enable: <ul style="list-style-type: none"> ■ 1: packet based ■ 2: module based ■ 3: both
trace	Specify one of the following datapath trace option: <ul style="list-style-type: none"> ■ acl-processing: Trace Mask for acl functionality ■ aesccm-decrypt: Trace Mask for aesccm-decrypt functionality ■ aesccm-encrypt: Trace Mask for aesccm-encrypt functionality ■ bridge: Trace Mask for bridge functionality ■ bwm: Trace Mask for bwm functionality ■ cp-dp-sp: Trace Mask for control path, slow path and fasth path messaging functionality ■ cp-dp-sp-message: Additional Trace Mask for control path, slow path and fasth path messaging functionality ■ dhcp: Trace Mask for dhcp functionality ■ dpi: Trace Mask for datapath DPI ■ event: Trace Mask for event functionality ■ fast: Trace Mask for fast functionality ■ ftp: Trace Mask for ftp functionality ■ gsi: Trace Mask for gsi functionality ■ heap: Trace Mask for heap functionality ■ icmp-error: Trace Mask for icmp error processing functionality ■ init: Trace Mask for init functionality ■ ip-re-assembly: Trace Mask for IP re-assembly functionality ■ ipsec-ctrl: Trace Mask for ipsec-ctrl functionality ■ ipsec-decrypt: Trace Mask for ipsec-decrypt functionality ■ ipsec-encrypt: Trace Mask for ipsec-encrypt functionality ■ mcast: Trace Mask for mcast functionality ■ mobility: Trace Mask for mobility functionality ■ nat: Trace Mask for nat functionality ■ netad: Trace Mask for netad functionality ■ peer: Trace Mask for peer functionality ■ port: Trace Mask for port functionality ■ pptp: Trace Mask for pptp functionality ■ pptp-ctrl: Trace Mask for pptp-ctrl functionality ■ recv: Trace Mask for recv functionality ■ route: Trace Mask for route functionality ■ rtsp: Trace Mask for rtsp functionality ■ send: Trace Mask for send functionality ■ session: Trace Mask for session functionality

Parameter	Description
	<ul style="list-style-type: none"> ■ sip-alg: Trace Mask for sip alg service functionality ■ skinny: Trace Mask for skinny functionality ■ station: Trace Mask for station functionality ■ tcp-termination: Trace Mask for datapath tcp termination functionality ■ tkip-alloc-err: Trace Mask for tkip-alloc-err functionality ■ tkip-ctrl: Trace Mask for tkip-ctrl functionality ■ tkip-decrypt: Trace Mask for tkip-decrypt functionality ■ tkip-encrypt: Trace Mask for tkip-encrypt functionality ■ trace-hex-mask: Configure Datapath Trace mask in Hex Form ■ trunk: Trace Mask for trunk functionality ■ tunnel: Trace Mask for tunnel functionality ■ user: Trace Mask for user functionality ■ vlan: Trace Mask for vlan functionality ■ vocera: Trace Mask for vocera functionality ■ wep-decrypt: Trace Mask for wep-decrypt functionality functionality ■ wep-encrypt: Trace Mask for wep-encrypt functionality functionality ■ wep-icmpfr: Trace Mask for wep-icmpfr functionality ■ xSec-ctrl: Trace Mask for xSec-ctrl functionality ■ xSec-decrypt: Trace Mask for xSec-decrypt functionality ■ xSec-encrypt: Trace Mask for xSec-encrypt functionality
trace-hex-mask <tmask>	Configure datapath trace mask in Hex format.
tuple	Configure datapath tracing by tuples in packet pipeline.
destination-ip	Specify the destination IP address (A.B.C.D).
destination-mac	Specify the destination MAC address (AA:BB:CC:DD:EE:FF).
ether-type	Specify the packet ethernet frame type.
packet-count	Specify the number of packets to trace.
protocol	Specify protocol number.
source-ip	Specify source IP address (A.B.C.D).
source-mac	Specify source MAC address (AA:BB:CC:DD:EE:FF).

Example

The following example enables the global packet tracing for all traffic.

```
(host) [mynode] (config) #pkt-trace-global
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Configure mode on Mobility Conductor.

pkt-trace-rap

```
pkt-trace-rap
  enable
    [[acl <acl>]][global][ingress <ingress>]] [trace-mask <trace-mask>] [[ap-name
  <ap-name>]][ip-addr <ip-addr>]]
```

Description

This command enables packet tracing in RAP datapath.

Parameter	Description
enable	Enables packet tracing in RAP datapath.
acl <acl>	Specifies name of the ACL.
[global]	Traces all packets.
ingress <ingress>	Traces packets from ingress.
trace-mask <trace-mask>	Specifies the trace mask. This value will be provided by Aruba technical support.
ap-name <ap-name>	Specifies name of an AP.
ip-addr <ip-addr>	Specifies IP address of an AP.

Example

The following example enables packet tracing in RAP datapath:

```
(host) [mynode] #pkt-trace-rap enable acl default trace-mask OA ap-name
ap215
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

poe-bounce

```
poe-bounce <slot/module/port>
  time-interval <down-time>
```

Description

This command disables poe for selected interface for specific duration. The default value for which poe is disabled is 3 seconds.

Parameter	Description
<slot/module/port>	Specify the gigabyte interface in <slot>/<module>/<port> format.
time-interval <down-time>	Set the time duration in seconds for poe to be disabled. 3-15

Example

The following example disables the poe for port 1 of gigabyte interface module 1 in slot 1.

```
(host)[mynode] #poe-bounce 1/1/1 time-interval 5
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

policy-domain

```
policy-domain group-profile <name of the profile>
  clone <source>
  controller <ip address> <macaddress>
  controller-v6 <ip address> <macaddress>
  no
```

Description

This command configures a policy domain profile to apply role-based ACL for users present in different controllers.

Only one domain group profile is supported in this release. The command should be executed in the /md node and the policy domain group profile supports IPv4 and IPv6 addresses but a combination of both is not supported.

Parameter	Description
<name of the profile>	Name of the profile.
controller <ip address>	IPv4 address of the controller.
controller-v6 <ip6 address>	IPv6 address of the controller.
<mac address>	Mac address of the controller.
no	Deletes the profile.

Example

The following example configures a policy domain profile,

```
(host) [md] policy-domain group-profile test
(host) [md] (Policy Domain Profile "test") controller 1.1.1.1
00:0a:95:9d:68:16
```

Command History

Release	Modification
ArubaOS 8.7.0.0	A new parameter, <code>clone</code> was added.
ArubaOS 8.6.0.0	Command introduced.

port-bounce

```
port-bounce <slot/module/port>  
  time-interval <down-time>
```

Description

This command shuts down the selected port for specific duration. The default value for which the port is shut down is 3 seconds.

Parameter	Description
<slot/module/port>	Specify the gigabyte interface in <slot>/<module>/<port> format.
time-interval <down-time>	Set the time duration in seconds for which the port is to be shut down. 3-15

Example

The following example shuts down the port 1 of gigabyte interface module 1 in slot 1 for 6 seconds.

```
(host)[mynode] #port-bounce 1/1/1 time-interval 6
```

Command History

Release	Modification

pptp ip local pool

```
pptp ip local pool <pool_name> <pool_start_address> [<pool_end_address>]
```

Description

This command configures an IP address pool for VPN users using PPTP. PPTP is an alternative to IPsec that is supported by various hardware platforms. PPTP is considered to be less secure than IPsec but also requires less configuration.

If VPN is used as an access method, you must specify the pool from which the user's IP address is assigned when the user negotiates a PPTP session.

Parameter	Description
<pool-name>	User-defined name for the address pool.
<pool_start_address>	Starting IP address for the pool.
<pool_end_address>	Ending IP address for the pool.

Related Commands

Command	Description
show vpdn pptp local pool	Displays the IP address pool for VPN users using Point-to-Point Tunneling Protocol. Use this command to see the used and free addresses in the pool.
vpdn group pptp	This command configures a PPTP VPN connection.

Example

The following example configures an IP address pool for PPTP VPN users:

```
(host) [mynode] (config) #pptp ip local pool pptp-pool1 172.16.18.1  
172.16.18.24
```

Command History

Release	Description
ArubaOS 8.0.0.0	Command Introduced.

priority-map

```
priority-map <name>  
  dot1p <priority> high  
  dscp <priority> high  
  no ...
```

Description

This command configures the ToS and CoS values used to map traffic into high priority queues. This command allows you to prioritize inbound traffic that is already tagged with 802.1p or IP ToS in hardware queues. You apply configured priority maps to ports on the managed device (using the `interface gigabitethernet` command). This causes the managed device to inspect inbound traffic on the port; when a matching QoS tag is found, the packet or flow is mapped to the specified queue.

Parameter	Description
<name>	User-defined name of the priority map.
dot1p	IEEE 802.1p priority value, or a range of values separated by a dash (-). 0-7
dscp	DSCP priority value, or a range of values separated by a dash (-). 0-63
no	Negates any configured parameter.

Example

The following example configures a priority map and applies it to a port:

```
(host) [mynode] (config) #priority-map pri1  
dscp 4-20 high  
dscp 60 high  
dot1p 4-7 high  
interface gigabitethernet 0/0/4  
priority-map pri1
```

Command History

process monitor

process monitor log|restart|

Description

This command validates the integrity of processes every 120 seconds. If a process does not respond during three consecutive 120-second timeout intervals, that process is flagged as non-responsive and the process monitor will create a log message, restart the process or reboot the managed device.

Parameter	Description
log	The process monitor creates a log message when a process fails to responding properly. This is the default behavior for the process monitor
restart	This parameter enables strict behavior for runtime processes. When you enable this option, the process monitor will restart processes that fail to responding properly.

The CLI command `process monitor log` enables logging for process monitoring. By default, whenever a process does not update a required file or send a heartbeat pulse within the required time limit, the process monitor records a critical log message, but does not restart any process. If you want the configure watchdog to restart a process once it fails to respond, use the `command process monitor restart` command.

Example

The following example changes the default process monitor behavior, so the process monitor restarts nonresponsive processes.

```
(host) [mynode] #process monitor restart
```

The `show process monitor statistics` command displays the current status of all the processes running under the process monitor watchdog. A partial example of the output of this command is shown below:

```
(host) (config) #show process monitor statistics

Process Monitor Statistics

All platforms	Base operating system.	Config mode on Mobility Conductor.

process reset

```
process reset wms
```

Description

This command performs an internal soft-reset of the module.

Parameter	Description
wms	WLAN Management System.

Example

```
(host) [mynode] #process reset wms
WARNING: Do you really want to perform an internal soft-reset of this module
[y/n]:
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

process restart

```
process restart <name> [core]
```

Description

This command restarts a process and optionally creates a core file.

Parameter	Description
<name>	Name of the process to restart.
[core]	Creates a core file

Example

The following example restarts the **dbsync** process and creates a core file:

```
(host) [mynode] #process restart dbsync core
WARNING: Do you really want to restart process: dbsync (y/n): y
Restarting: dbsync
```

The following example restarts the **tm** process and creates a core file:

```
(host) [mynode] #process restart tm
WARNING: Do you really want to restart process: tm (y/n): y
Restarting: tm
```

Command History

Release	Modification
ArubaOS 8.10.0.0	The tm process was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

process snapshot

```
process snapshot <name> <pid>
```

Description

This command interrupts a process temporarily to create a snapshot file.

Parameter	Description
<name>	Name of the process to snapshot.
<pid>	Process id of the process to snapshot.

Example

The following example restarts the **dbsync** process and creates a core file:

```
(host) [mynode] #process snapshot
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

product serial-number

```
product serial-number <sl-num>
```

Description

This command configures the product serial-number for a managed device on a Virtual Machine (VM).

Parameter	Description
<sl-num>	Configure the serial number provided by Aruba.

Before you install ArubaOS on a VM instead of a physical Arubacontroller, contact your Aruba sales representative or authorized reseller and request a VM serial number, then use this serial number as a part of your VM configuration. This serial number is a randomly generated string in the format *DC<7-digit-string>*, for example, **DC0000001**. You must configure the VM serial number and identify the passphrase for that device before you can generate a license key for that specific VM configuration.

Example

The following example configures a product serial-number:

```
(host) [mynode] #product serial-number 0123456789
```

Related Commands

Command	Description
show inventory	Display the Mobility Conductor serial number used to generate licenses for a Mobility Conductor deployment.
show license passphrase	Display the Mobility Conductor passphrase used to generate licenses for a Mobility Conductor deployment.

prompt

```
prompt <new-prompt>
```

Description

This command changes the prompt text. You can use any alphanumeric character, punctuation, or symbol character. To use spaces, plus symbols (+), question marks (?), or asterisks (*), enclose the text in quotes.

You cannot alter the parentheses that surround the prompt text, or the greater-than (>) or hash (#) symbols that indicate user or enable CLI mode.

Parameter	Description
<code>new-prompt</code>	The prompt text displayed by the Mobility Conductor. 1-64 <hostname>

Example

The following example changes the prompt text to "It's a new day!".

```
(host) [mynode] (config) #prompt "It's a new day!"  
(It's a new day!) (config) #
```

```

Description

This command provisions or reprovisions an AP.

You do not need to provision APs before installing and using them. The exceptions are outdoor APs, which have antenna gains that you must provision before they can be used, and APs configured for mesh. You must provision the AP before you install it as a mesh node in a mesh deployment.

Users less familiar with this process may prefer to use the **Provisioning** page in the WebUI to provision an AP.

Provisioned or re-provisioned values do not take effect until the AP is rebooted. APs reboot automatically after they are successfully reprovisioned.

To enable cellular uplink for a Remote AP, the Remote AP must have the device driver for the USB data card and the correct configuration parameters. ArubaOS includes device drivers for the most common hardware types, but you can use the **usb** commands in this profile to configure a Remote AP to recognize and use an unknown USB modem type.

Parameter	Description
a-ant-bearing	<p>Determines the horizontal coverage distance of the 802.11a (5 GHz) antenna from True North.</p> <p>From a planning perspective, the horizontal coverage pattern does not consider the elevation or vertical antenna pattern.</p> <p>NOTE: This parameter is supported on outdoor APs only. If you use this parameter to configure an indoor AP, an error message is displayed.</p> <p>0-360 Decimal Degrees</p>
a-ant-gain	<p>Antenna gain for 802.11a (5GHz) antenna.</p>
a-ant-pol	<p>Antenna polarization value for 5GHz radio. Use one of the following parameters:</p> <ul style="list-style-type: none"> ■ 0: CO-Polarized ■ 1: Cross-Polarized
a-ant-tilt-angle	<p>Directs the angle of the 802.11a (5GHz) antenna for optimum coverage. Use a - (negative) value for downtilt and a + (positive) value for uptilt.</p> <p>NOTE: This parameter is supported on outdoor APs only. If you use this parameter to configure an indoor AP, an error message is displayed.</p> <p>-90 to +90 Decimal Degrees</p>
a-antenna	<p>Antenna use for 5 GHz (802.11a) frequency band. Use one of the following parameters:</p> <ul style="list-style-type: none"> ■ 1: Use antenna 1 ■ 2: Use antenna 2 ■ both: Use both antennas (default) <p>1, 2, both</p>

Parameter	Description
	both
altitude	Altitude, in meters, of the AP. NOTE: This parameter is supported on outdoor APs only. If you use this parameter to configure an indoor AP, an error message is displayed.
ap-group	Name of the AP group to which the AP belongs.
ap-lldp-pse-detect	Enabling causes the AP to detect the POE type via LLDP POE TLV. Use one of the following parameters: <ul style="list-style-type: none"> ■ enabled: The AP uses PSE TYPE in the POE TLV to detect the PSE type. ■ disabled: The AP detects the POE using the HW classification.
ap-name	Name of the AP to be provisioned.
ap-poe-power-optimization	Enables optimization to minimize the POE draw of the AP. Enabling optimization may disable some parts of the AP. Disabling optimization ensures all features are enabled.
ap2xx-prestandard-poe-detection	Configures the pre-standard PoE detection on 200 Series APs. The POE+ pre-standard detection is only available on 200 Series APs. It consists of a basic voltage comparator. If the line voltage is equal to or greater than 51 V, the PSE is assumed to be 802.3at compatible.
apdot1x-factory-cert	Enables AP to use factory certificates when doing 802.1x EAP-TLS.
apdot1x-passwd	Password of the AP to authenticate to 802.1X using PEAP.
apdot1x-timeout-bypass	Enables AP to be provisioned when 802.1X authentication times out.
apdot1x-timeout-retries	Sets the apdot1x timeout threshold. If the auth timeouts over this threshold, the AP will bypass apdot1x auth.
apdot1x-tls	Enables AP to 802.1x using EAP-TLS.

Parameter	Description
apdot1x-tls-suffix	Enables AP to use EAP-TLS username suffix.
apdot1x-tls-suffix-domain <apdot1x-tls-suffix-domain>	Set the suffix domain for AP dot1x EAP-TLS username. If defined, use EAP-TLS username as suffix, else use aruba.ap . 1- 63 string length
apdot1x-username	Username of the AP to authenticate to 802.1X using PEAP.
aruba-modem-apn <aruba-modem-apn>	Configures the APN of Aruba 4G LTE modem.
aruba-modem-plmn <aruba-modem-plmn>	Configures the PLMN of Aruba 4G LTE modem.
cellular_nw_preference 3g-only 4g-only advanced auto	<p>This setting allows you to select how the modem should operate.</p> <ul style="list-style-type: none"> ■ auto (default): In this mode, the modem firmware will control the cellular network service selection; so the cellular network service failover and fallback is not interrupted by the Remote AP. ■ 3g_only: Locks the modem to operate only in 3G. ■ 4g_only: Locks the modem to operate only in 4G. ■ advanced: The Remote AP controls the cellular network service selection based on the Received Signal Strength Indication (RSSI) threshold-based approach. Initially the modem is set to the default auto mode. This allows the modem firmware to select the available network. The Remote AP determines the RSSI value for the available network type (for example 4G), checks whether the RSSI is within required range, and if so, connects to that network. If the RSSI for the modem's selected network is not within the required range, the Remote AP will then check the RSSI limit of an alternate network (for example, 3G), and reconnect to that alternate network. The Remote AP will repeat the above steps each time it tries to connect using a 4G multimode modem in this mode.

Parameter	Description
cert-DN	The Server Certificate CN for Identity
dns-server-ip	IP address of the DNS server for the AP.
dns-server-ip6	IPv6 address of the DNS server for the AP.
domain-name	Domain name for the AP.
external-antenna	Use an external antenna with the AP.
fqln	FQLN for the AP, in the format <APname.floor.building.campus>.
g-ant-bearing	<p>Determines the horizontal coverage distance of the 802.11g (2.4GHz) antenna from True North.</p> <p>From a planning perspective, the horizontal coverage pattern does not consider the elevation or vertical antenna pattern.</p> <p>NOTE: This parameter is supported on outdoor APs only. If you use this parameter to configure an indoor AP, an error message is displayed.</p> <p>0-360 decimal degrees</p>
g-ant-gain	Antenna gain for 802.11g (2.4GHz) antenna.
g-ant-pol	<p>Antenna polarization value for 2.4GHz radio. Use one of the following parameters:</p> <ul style="list-style-type: none"> ■ 0: CO-Polarized ■ 1: Cross-Polarized
g-ant-tilt-angle	<p>Directs the angle of the 802.11g (2.4GHz) antenna for optimum coverage. Use a - (negative) value for downtilt and a + (positive) value for uptilt.</p> <p>NOTE: This parameter is supported on outdoor APs only. If you use this parameter to configure an indoor AP, an error message is displayed.</p> <p>-90 to +90 Decimal Degrees</p>

Parameter	Description
g-antenna	Antenna use for 2.4 GHz (802.11g) frequency band. Use one of the following parameters: <ul style="list-style-type: none"> ■ 1: Use antenna 1 ■ 2: Use antenna 2 ■ both: Use both antennas 1, 2, both both
gateway	IP address of the default gateway for the AP.
gateway6	IPv6 address of the default gateway for the AP.
ikepsk	IKE preshared key for the AP.
ikepsk-hex-based	Specify if the ikepsk is hex-based or text-based. (set -> Hex, unset -> Text).
iot-ant-gain <gain>	Configures an antenna gain value for APs with external antennas.
installation	Specifies the type of installation (indoor or outdoor). The default parameter automatically selects an installation mode based upon the AP model type. indoor, outdoor
ip6addr	Static IPv6 address of the AP.
ip6prefix	The prefix of static IPv6 address of the AP.
ipaddr	Static IP address for the AP.
latitude	Latitude coordinates of the AP. Use the format: Degrees, Minutes, Seconds (DMS). For example: 37 22 00 N
link-priority-cellular <link-priority-cellular>	Sets the priority of the cellular uplink. By default, the cellular uplink is a lower priority than the wired uplink; making the wired link the primary link and the cellular link the secondary or backup link. Configuring the cellular link with a higher priority than your wired link priority will set your cellular link as the primary link.

Parameter	Description
link-priority-ethernet <link-priority-ethernet>	Sets the priority of the wired uplink. Each uplink type has an associated priority; wired ports having the highest priority by default.
link-priority-wifi <link-priority-wifi>	Sets the priority of the Wi-Fi uplink. Both Wi-Fi and wired uplink types have equal priority, depending on their availability. If one of the uplink types is not available, the other uplink type is set as the primary link by default. However if both the uplink types are available, one of them is chosen randomly as the primary link.
longitude	Longitude coordinates of the AP. Use the DMS format. For example: 122 02 00 W
master/conductor	Name or IP address of the Mobility Conductor.
master/conductor-preference	Configures the preferred IP protocol (IPv4 or IPv6) for AP master/ conductor discovery.
mesh-role	Configures the AP to operate as a mesh node. You assign one of four roles: mesh auto , mesh portal , mesh point or remote mesh point . If you select none , the AP operates as a thin AP.
mesh-sae	<p>Enables or disables Simultaneous Authentication of Equals (SAE) on a mesh network. This option offers enhanced security over the default wpa2-psk-aes mesh security setting, and provides secure, attack-resistant authentication using a PSK. SAE supports simultaneous initiation of a key exchange, allowing either party to initiate an exchange or both parties to initiate a key exchange simultaneously</p> <p>To use the SAE feature, you must enable this parameter on all mesh nodes (points and portals) in the network, to prevent mesh link connectivity issues.</p> <p>NOTE: This is a Beta feature only. This parameter should be kept "disabled" for this release.</p>
netmask	Netmask for the IP address.

Parameter	Description
ocsp_default	If this parameter is set to 0 (default accept) and the certificate status is unknown, the server certificate is considered valid and the Remote AP comes up. If this parameter is set to 1 (default deny) and the certificate status is unknown, the server certificate is considered revoked and the Remote AP does not come up. By default, OCSF default is set to 0 (default accept).
no	Negates any configured parameter.
pap-passwd	PAP password for the AP. You can use special characters in the PAP password. Following are the restrictions: <ul style="list-style-type: none"> ■ You cannot use double-byte characters ■ You cannot use a tilde (~) ■ You cannot use a tick (') ■ If you use quotes (single or double), you must use the backslash (\) before and after the password
pap-user	PAP username for the AP.
pkcs12-passphrase	Passphrase in PKCS12 format.
pppoe-chap-secret	PPPoE CHAP secret key for the AP.
pppoe-passwd	PPPoE password for the AP.
pppoe-service-name	PPPoE service name for the AP.
pppoe-user	PPPoE username for the AP.
preferred_uplink	Choose AP preferred uplink interface (eth0-eth1). This is only applicable to AP-318, AP-374, AP-375, and AP-377 access points.
radio-0-5ghz-ant-gain <radio-0-5ghz-ant-gain>	Antenna gain for Radio 0 (5 GHz) antenna. NOTE: This parameter is only needed for APs that support dual 5 GHz mode.
radio-0-5ghz-ant-pol <radio-0-5ghz-ant-pol>	Antenna polarization value for Radio 0 (5 GHz) antenna. Use one of the following parameters:

Parameter	Description
	<ul style="list-style-type: none"> ■ 0: CO-Polarized ■ 1: Cross-Polarized <p>NOTE: This parameter is only needed for APs that support dual 5 GHz mode.</p>
radio-1-5ghz-ant-gain <radio-1-5ghz-ant-gain>	<p>Antenna gain for Radio 1 (5 GHz) antenna.</p> <p>NOTE: This parameter is only needed for APs that support dual 5 GHz mode.</p>
radio-1-5ghz-ant-pol <radio-1-5ghz-ant-pol>	<p>Antenna polarization value for Radio 1 (5 GHz) antenna. Use one of the following parameters:</p> <ul style="list-style-type: none"> ■ 0: CO-Polarized ■ 1: Cross-Polarized <p>NOTE: This parameter is only needed for APs that support dual 5 GHz mode.</p>
read-bootinfo	<p>Retrieves current provisioning parameters of the specified AP.</p> <p>NOTE: This parameter can only be used on the Mobility Conductor.</p>
remote-ap	<p>This is a remote AP.</p>
reprovision	<p>Provisions one or more APs with the values in the provisioning-params workspace. To use reprovision, you must use read-bootinfo to retrieve the current values of the APs into the provisioning-ap-list.</p> <p>NOTE: This parameter can only be used on the Mobility Conductor.</p>
reset-bootinfo	<p>Restores factory default provisioning parameters to the specified AP.</p> <p>NOTE: This parameter can only be used on the Mobility Conductor.</p>

Parameter	Description
sch-mode-radio-0	If you are provisioning an 802.11n-capable AP, you can issue the sch-mode-radio-0 command to enable single-chain mode for the selected radio. AP radios in single-chain mode will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This setting is disabled by default.
sch-mode-radio-1	If you are provisioning an 802.11n-capable AP, you can issue the sch-mode-radio-1 command to enable single-chain mode for the selected radio. AP radios in single-chain mode will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This setting is disabled by default.
sch-mode-radio-6ghz	If you are provisioning an 802.11n-capable AP, you can issue the sch-mode-radio-6Ghz command to enable single-chain mode for the selected radio. AP radios in single-chain mode will transmit and receive data using only legacy rates and single-stream HT rates up to MCS 7. This setting is disabled by default.
server-ip	IPv4 or IPv6 address of the managed device from which the AP boots.
server-name	DNS name of the managed device from which the AP boots.
set-ikepsk-by-addr	Sets a IKE preshared key to correspond to a specific IP address.
set-trust-anchor	Set trust anchor for the AP.
syslocation	User-defined description of the location of the AP.
trustanchor	Name of the trust anchor.
uplink-vlan <uplink-vlan>	<p>If you configure an uplink VLAN on an AP connected to a port in trunk mode, the AP sends and receives frames tagged with this VLAN on its Ethernet uplink. By default, an AP has an uplink vlan of 0, which disables this feature.</p> <p>NOTE: If an AP is provisioned with an uplink VLAN, it <i>must be connected to a trunk mode port</i> or the AP's frames will be</p>

Parameter	Description
	dropped.
usb-csr	The USB storage for CSR and private key file.
usb-dev	The USB device identifier, if the device is not already supported.
usb-dial	The dial string for the USB modem. This parameter only needs to be specified if the default string is not correct.
<pre>usb-modeswitch "-v <default_vendor> -p <default_product> -V <target_vendor> -P <target_product> -M <message_content>"</pre>	<p>USB cellular devices on Remote APs typically register as modems, but may occasionally register as a mass-storage device. If a Remote AP cannot recognize its USB cellular modem, use the <code>usb-modeswitch</code> command to specify the parameters for the hardware model of the USB cellular data-card.</p> <p>NOTE: You must enclose the entire modeswitch parameter string in quotation marks.</p>
usb-init	<p>The initialization string for the USB modem. This string configures the AP Name setting of the USB modem. For the USB modem to understand this string, the value entered should adhere to one of the following formats:</p> <ul style="list-style-type: none"> ■ Use double-quotes and prefix them with a backslash character. See example below: "AT+CGDCONT=1,\"IP\", \"APN\"" ■ Use single-quote instead of double-quotes. AP translates single-quote into double-quotes. See example below: "AT+CGDCONT=1,'IP','APN'" ■ Use the string begin-end pair without double quotes. See example below: AT+CGDCONT=1,'IP','APN' <p>■ In some cases, the 4G/LTE modem requires the configuration of two AP Names during USB initialization. The first AP Name initiates the connection to obtain an IP address, and the second AP Name sends and receives</p>

Parameter	Description
	<p>data. Use the ; delimiter character to create two separate strings for the AP Names in the command. See example below:</p> <pre>"AT+CGDCONT=1,\"IP\", \"APN1\";1,1,\"APN2\""</pre> <p>NOTE: You must obtain the AP Name from your ISP and ensure that each AP Name entry follows the manufacturer's AT command reference.</p>
usb-passwd	A PPP password, if provided by the cellular service provider
usb-power-mode auto enable disable	Sets the USB power mode to control the power to the USB port.
usb-tty	The TTY device path for the USB modem. This parameter only needs to be specified if the default path is not correct.
usb-tty-control	The TTY device control path for the USB modem. This parameter only needs to be specified if the default path is not correct.
usb-type	<p>Specify the USB driver type.</p> <ul style="list-style-type: none"> ■ acm: Use ACM driver ■ airprime: Use Airprime driver ■ beceem-wimax: Use Beceem driver for 4G-WiMAX ■ ether: Use CDC Ether driver for direct IP 4G device ■ hso: Use HSO driver for newer Option ■ none: Disable 3G or 2G network on USB ■ option: Use Option driver ■ pantech-3g: Same as "pantech-uml290" - to support upgrade ■ pantech-uml290: Use Pantech USB driver for UML290 device ■ ptumlbnet: Use Pantech USB driver for 4G device ■ rndis: Use a RNDIS driver for a 4G device ■ sierra-evdo: Use EVDO Sierra Wireless driver ■ sierra-gsm: Use GSM Sierra Wireless driver ■ sierrausbnet: Use SIERRA Direct IP driver for 4G device

Parameter	Description
	<ul style="list-style-type: none"> ■ storage: Use USB flash as storage device for storing Remote AP certificates
usb-user	The PPP username provided by the cellular service provider.
wifi-uplink	Enables the AP to use Wi-Fi uplink.

Provisioning a Single AP

To provision a single AP:

1. Use the **read-bootinfo** option to read the current information from the deployed AP you wish to re-provision.
2. Use the **show provisioning-ap-list** command to see the AP to be provisioned.
3. Use the **copy-provisioning-params** option to copy the AP's parameter values to the provisioning-params workspace.
4. Use the provision-ap options to set new values. Use the **show provisioning-params** command to display parameters and values in the provisioning-params workspace. Use the **clear provisioning-params** command to reset the workspace to default values.
5. Use the **reprovision** option to provision the AP with the values in provisioning-params workspace. The AP automatically reboots.

Provisioning Multiple APs at a Time

You can change parameter values for multiple APs at a time, however, note the following:

- You cannot provision the following AP-specific options on multiple APs:
 - ap-name
 - ipaddr
 - pap-user
 - pap-passwd
 - ikepsk
 - If any of these options are already provisioned on the AP, their values are retained when the AP is re-provisioned.
- The values of the server-name, a-ant-gain, or g-ant-gain options are retained if they are not re-provisioned.
- All other values in the provisioning-params workspace are copied to the APs.

To provision multiple APs at the same time:

1. Use the **read-bootinfo** to read the current information from each deployed AP that you wish to provision.

The AP parameter values are written to the provisioning-ap-list. To reconfigure multiple APs, the APs must be present in the provisioning-ap-list. Use the **show provisioning-ap-list** command to see the APs that will be provisioned. Use the **clear provisioning-ap-list** command to clear the provisioning-ap-list.

2. Use the **copy-provisioning-params** option to copy an AP's parameter values to the provisioning-params workspace.
3. Use the provision-ap options to set new values. Use the **show provisioning-params** command to display parameters and values in the provisioning-params workspace. Use the **clear provisioning-params** command to reset the workspace to default values.
4. Use the **reprovisionall** option to provision the APs in the provisioning-ap-list with the values in provisioning-params workspace. All APs in the provisioning-ap-list automatically reboot.

The following are useful commands when provisioning one or more APs:

- `show|clear provisioning-ap-list` displays or clears the APs that will be provisioned.
- `show|clear provisioning-params` displays or resets values in the provisioning-params workspace.
- `show ap provisioning` shows the provisioning parameters an AP is currently using.

Example

The following example changes the IP address of the Mobility Conductor on the AP:

```
(host) [mynode] (config) #provision-ap
(host) [mynode] (config-submode)read-bootinfo ap-name lab103
(host) [mynode] (config-submode)show provisioning-ap-list
(host) [mynode] (config-submode)copy-provisioning-params ap-name lab103
(host) [mynode] (config-submode)master/ conductor 10.100.102.210
(host) [mynode] (config-submode)reprovision ap-name lab103
```

The following example configures the preferred IP protocol for AP master/ conductor discovery:

```
(host) [mynode] (config) #provision-ap
(host) [mynode] (config-submode)master/ conductor -preference ipv4
```

The following example configures the APN and PLMN of Aruba MDM-USB-LTE 4G modem:

```
(host) [mynode] (config) #provision-ap
(host) [mynode] (config-submode) #aruba-modem-apn <aruba-modem-apn>
(host) [mynode] (config-submode) #aruba-modem-plmn <aruba-modem-plmn>
```

Command History

Release	Modification
ArubaOS 8.10.0.0	The following parameters were introduced: <ul style="list-style-type: none">■ <code>aruba-modem-apn <aruba-modem-apn></code>■ <code>aruba-modem-plmn <aruba-modem-plmn></code>■ <code>iot-ant-gain <gain></code>
ArubaOS 8.8.0.0	The following parameters were introduced: <ul style="list-style-type: none">■ <code>apdot1x-timeout-bypass</code>■ <code>apdot1x-timeout-retries</code>
ArubaOS 8.7.0.0	The <code>master-preference</code> parameter was introduced.
ArubaOS 8.5.0.0	The following parameters were added: <ul style="list-style-type: none">■ <code>link-priority-wifi</code>■ <code>wifi-uplink</code>
ArubaOS 8.4.0.0	The following parameters were added: <ul style="list-style-type: none">■ <code>apdot1x-tls-suffix</code>■ <code>apdot1x-tls-suffix-domain</code>■ <code>mesh-auto</code>■ <code>preferred_uplink</code>
ArubaOS 8.3.0.0	The following parameters were added: <ul style="list-style-type: none">■ <code>radio-0-5ghz-ant-gain</code>■ <code>radio-0-5ghz-ant-pol</code>■ <code>radio-1-5ghz-ant-gain</code>■ <code>radio-1-5ghz-ant-pol</code>
ArubaOS 8.2.0.0	The following parameters were added: <ul style="list-style-type: none">■ <code>apdot1x-factory-cert</code>■ <code>apdot1x-tls</code>■ <code>a-ant-pol</code>■ <code>g-ant-pol</code>■ <code>ap-lldp-pse-detect</code>
ArubaOS 8.1.0.0	The <code>server-ip</code> parameter was modified to accept IPv6 address.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms, except for the parameters noted in the syntax table.	Base operating system, except for the parameters noted in the syntax table.	Config mode on Mobility Conductor.

pwd

pwd

Description

This command displays the full path of the current configuration node.

Example

The following example indicates that the current node-path is **/mm/mynode**:

```
(host) [mynode] (config) #pwd
/mm/mynode
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

read-bootinfo

```
read-bootinfo {ap-name <ap-name>}|{ip-addr <ip-addr>}|{ip6-addr <ip6-addr>}|{wired-  
mac <wired-mac>}
```

Description

This command retrieves the current provisioning parameters of an AP.

Parameter	Description
ap-name <ap-name>	Retrieves the current provisioning parameters of an AP for specified AP name.
ip-addr <ip-addr>	Retrieves the current provisioning parameters of an AP for specified IP address.
ip6-addr <ip6-addr>	Retrieves the current provisioning parameters of an AP for specified IPv6 address.
wired-mac <wired-mac>	Retrieves the current provisioning parameters of an AP for specified wired MAC address.

Example

The following example retrieves the current provisioning parameters of an AP named ap-205:

```
(host) [mynode] #read-bootinfo ap-name ap-205
```

Command History

Release	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

reload

```
reload
  force
  device-mac
```

Description

This command reboots the managed device if required after making configuration changes or under the guidance of Aruba Networks customer support. The `reload` command powers down the managed device, making it unavailable for configuration. After the managed device reboots, you can access it over a local console connected to the serial port, or through an SSH, Telnet, or WebUI session.

Starting from ArubaOS 8.11.0.0, the **reload** command can be issued only from the **/mm** and **/mm/mynode** nodes of the Mobility Conductor.

Parameter	Description
<code>force</code>	Forces reboot without waiting for confirmation.
<code>device-mac</code>	Specifies the device MAC address for reboot.

Example

The following restarts the managed device without waiting for confirmation:

```
(host) [mynode] #reload force
System will now restart!
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The command can be issued only from the /mm and /mm/mynode nodes of the Mobility Conductor.
ArubaOS 8.0.0.0	Command introduced.

Command Information

All platforms	Base operating system.	Enable mode on Mobility Conductor.

reload-peer-sc

reload-peer-sc

Description

This command reboots the peer Supervisor Card if required after making configuration changes or under the guidance of Aruba Networks customer support.

This command is available for chassis system only.

Example

```
(host) [mynode] #reload-peer-sc
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The command can be issued only from the /mm and /mm/mynode nodes of the Mobility Conductor.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

rename

```
rename <filename> <newfilename>
```

Description

This command renames an existing system file on the controller. You can use a combination of numbers, letters, and punctuation (periods, underscores, and dashes) to rename a file. The new name takes affect immediately.

Make sure the renamed file uses the same file extension as the original file. If you change the file extension, the file may be unrecognized by the system. For example, if you have an existing file named `upgrade.log`, the new file must include the `.log` file extension.

You cannot rename the active configuration currently selected to boot the controller. If you attempt to rename the active configuration file, the controller returns the following message:

```
Cannot rename active configuration file
```

To view a list of system files, and for more information about the directory contents, see [dir on page 589](#).

Parameter	Description
<code>filename</code>	An alphanumeric string that specifies the current name of the file on the system.
<code>newfilename</code>	An alphanumeric string that specifies the new name of the file on the system.

Example

The following command changes the file named **test_configuration** to **deployed_configuration**:

```
(host) [mynode] (config) #rename test_configuration deployed_configuration
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

reprovision

```
reprovision {wired-mac <wired-mac> | ap-name <ap-name> | ip-addr <ip-addr> | ip6-addr <ip6-addr> | serial-num <serial-num> | all}
```

Description

This command sends current provisioning-profile to access points.

Parameter	Description
all	Reprovisions all access points listed in provisioning_ap_list
ap-name <ap-name>	Reprovisions an AP with the specified AP name.
ip-addr <ip-addr>	Reprovisions an AP with the specified IP address.
ip6-addr <ip6-addr>	Reprovisions an AP with the specified IPv6 address.
serial-num <serial-num>	Reprovisions an AP with the specified serial number.
wired-mac <wired-mac>	Reprovisions an AP with the specified MAC address.

Example

Access the CLI and use the following command to reprovision an AP **test**:

```
(host) [mynode] #reprovision ap-name test
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

reset-bootinfo

```
reset-bootinfo
  ap-name
  ip-addr
  wired-mac
```

Description

This command restores the factory default values for an access point.

Parameter	Description
ap-name <ap-name>	Restores the factory default values for the specified name of the access point.
ip-addr <ip-addr>	Restores the factory default values for the specified IP address of the access point.
wired-mac <wired-mac>	Restores the factory default values for the specified MAC address of the AP.

Example

Access the CLI and use the following command to restore factory default values for an access point with MAC address **00:1a:1e:aa:bb:cc**:

```
(host) [mynode] #reset-bootinfo wired-mac 00:1a:1e:aa:bb:cc
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

replace-config-reboot

```
replace-config-reboot <filename1> <config-path1> <filename2> <config-path2>
```

Description

This command is used to replace the configuration in a stand-alone controller and the controller will reboot with provided configuration file. The replace-config-reboot command also copies the current node config of /mm/mynode and /mm nodes to the corresponding backup files named mynode_replace_reboot_backup and mm_replace_reboot_backup respectively.

```
(VMC) [mynode] #dir
-rw-r--r--    1 root  root   42974 Oct 14 04:39 mynode_replace_reboot_backup
-rw-r--r--    1 root  root  114345 Aug  8 23:58 mm_replace_reboot_backup
```

Parameter	Description
filename1	The name of the configuration file in flash directory of stand-alone controller
filename2	The name of the configuration file in flash directory of stand-alone controller
config-path1	If configuration file has to be applied only at /mm node then set <config-path1> to /mm.
config-path2	If configuration file has to be applied only at /mm/mynode node then set <config-path1> to /mm/mynode.

Example

Below command will apply the template files at /mm and /mm/mynode nodes.

Applying template files at /mm node and at /mm/mynode node

```
(standalone) [mynode] (config) #configuration node replace-config-reboot
mmfile.cfg /mm mdfile.cfg /mm/mynode
Controller will be rebooted with provided configuration file. An improper
configuration might prevent controller to come up. Do you wish to continue ?
[y/n]: y
(VMC) [mynode] (config) #
(VMC) [mynode] (config) #
[11:39:59]:Starting reboot me
[11:39:59]:Shutdown processing started
```

Command History

Release	Modification
ArubaOS 8.6.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	config mode on stand-alone controllers.

restore

```
restore
  config
  factory_default
  flash
```

Description

This command restores the file or configuration. Use the `backup flash` command to tar and compress flash directories to the `flashbackup.tar.gz` file.

Parameter	Description
<code>config</code>	Restores configuration directories from a <code>configbackup.tar.gz</code> file.
<code>factory_default</code>	Restores factory default settings.
<code>flash</code>	Restores important directories from <code>flashbackup.tar.gz</code> file.

Example

The following command restores directories from the `flashbackup.tar.gz` file:

```
(host) [mynode] #restore flash
Please wait while we restore the flash backup.....
Flash restored successfully.
Please reload (reboot) the controller for the new files to take effect.
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

rf am-scan-profile

```
<profile-name>  
  clone <profile>  
  dwell-time-active-channel  
  dwell-time-dos-channel  
  dwell-time-other-reg-domain-channel  
  dwell-time-rare-channel  
  dwell-time-reg-domain-channel  
  no  
  scan-mode
```

Description

Configure an Air Monitor (AM) scanning profile. Channels are categorized into the following types:

Active Channel: This qualifier indicates that wireless activity (for example, a probe request) is detected on this channel by the presence of an AP or other 802.11 activity.

All Regulatory Domain Channels: A valid non-overlapping channel that is in the regulatory domain of at least one country.

Rare Channels: Channels that fall into a frequency range outside of the regulatory domain; 2484 MHz and 4900MHz-4995MHz (J-channels), and 5000-5100Mhz.

Regulatory Domain Channels: A channel that belongs to the regulatory domain of the country in which the AP is deployed. The set of channels that belong to this group is a subset of the channels in all-reg-domain channel group.

Parameter	Description
<profile-name>	Name of this instance of the profile. 1-63 characters
clone <profile>	Copy data from another AM scanning profile
dwell-time-active-channel	Dwell time (in ms) for channels where there is wireless activity. 100-32768 ms 500 ms
dwell-time-dos-channel	Dwell time (in ms) to contain rogue devices. 100-32768 ms 500 ms
dwell-time-other-reg-domain-channel	Dwell time (in ms) for channels not in the APs regulatory domain. 100-32768 ms

Parameter	Description
	250 ms
<code>dwell-time-rare-channel</code>	Dwell time (in ms) for rare channels. 100-32768 ms 100 ms
<code>dwell-time-reg-domain-channel</code>	Dwell time (in ms) for AP's Regulatory domain channels 100-32768 ms 250 ms
<code>no</code>	Delete the command
<code>scan-mode</code>	Set the scanning mode for the radio.
<code>all-reg-domain</code>	Scan channels in all regulatory domain
<code>rare</code>	Scan <i>all</i> channels (all regulatory domains and rare channels)
<code>reg-domain</code>	Scan channels in the APs regulatory domain

Command History

Release	Modification
ArubaOS 8.5.0.0	The <code>dwell-time-dos-channel</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All Platforms	RFProtect.	Config mode on Mobility Conductor.

rft

```
rft test profile ht-link-quality ap-name <ap-name> [dest-mac <dest-mac> [radio {0|1}mcs]]
```

```
rft test profile link-quality {ap-name <ap-name> dest-mac <dest-mac> [phy {a|g}|radio {0|1}] | bssid <bssid> dest-mac <dest-mac> | ip-addr <ip-addr> dest-mac <macaddr> [phy {a|g}|radio {0|1} | ip6-addr <ip6-addr> dest-mac <macaddr> [phy {a|g}|radio {0|1}]]
```

```
rft test profile raw {ap-name <name> dest-mac <dest-mac> [phy {a|g}|radio {0|1}] | bssid <bssid> dest-mac <dest-mac> | ip-addr <ip-addr> dest-mac <dest-mac> [phy {a|g}|radio {0|1}]]
```

Description

This command is used for RF troubleshooting. This command can run predefined test profiles for antenna connectivity, link quality, or raw testing. You should only run these commands when directed to do so by an Aruba support representative.

Parameter	Description
ap-name	Name of the AP that performs the test.
dest-mac	MAC address of the client to be tested.
phy	802.11 type, either a or g. a g
radio	Radio ID, either 0 or 1.
bssid	BSSID of the AP that performs the test. 0 1
ip-addr	IP address of the AP that performs the test.
ip6-addr	IPv6 address of the AP that performs the test.

Command History

Version	Modification

Description

This command configures the Adaptive Radio Management (ARM) profile. Adaptive Radio Management (ARM) is a radio frequency (RF) resource allocation algorithm that allows each AP to determine the optimum channel selection and transmit power setting to minimize interference and maximize coverage and throughput. This command configures an ARM profile that you apply to a radio profile for the 5 GHz or 2.4 GHz frequency band (see [rf dot11a-radio-profile on page 1196](#) or [rf dot11g-radio-profile on page 1228](#)).

Parameter	Description
<profile>	Name of this instance of the profile. The name must be 1-63 characters. default
40MHz-allowed-bands	The specified setting allows ARM to determine if 40 MHz mode of operation is allowed on the 5 GHz or 2.4 GHz frequency band only, on both frequency bands, or on neither frequency band. All/None/ a-only/g-only a-only
All	Allows 40 MHz channels on both the 5 GHz (802.11a) and 2.4 GHz (802.11b/g) frequency bands.
None	Disallows use of 40 MHz channels.

Parameter	Description
a-only	Allows use of 40 MHz channels on the 5 GHz (802.11a) frequency band only.
g-only	Allows use of 40 MHz channels on the 2.4 GHz (802.11b/g) frequency band only.
80MHz-support	If enabled, 80 MHz channels can be used in the 5 GHz frequency band on APs that support 802.11ac. enabled
160MHz support	Specifies which 160 MHz mode to be assigned. This parameter does not apply to 2.4 GHz frequency band.
Auto	Allows automatic selection of contiguous frequency.
Contiguous-only	Allows to assign contiguous only 160 MHz channel bandwidth.
Non-contiguous-only	Allows to assign non-contiguous 160 MHz channel bandwidth.
None	This sub-parameter disallows assigning 160 MHz channel bandwidth.
acceptable-coverage-index	The minimal coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be. This setting applies to multi-band implementations only. 1-6 4
active-scan	When active-scan is enabled, an AP initiates active scanning via probe request. This option elicits more information from nearby APs, but also creates additional management traffic on the network. This feature is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Aruba Technical Support. disabled
aggressive-scan	When this feature is enabled, an AP radio with no clients will scan channels every second. enabled
assignment	Activates one of four ARM channel/power assignment modes. single-band (new installations only)

Parameter	Description
disable	Disables ARM channel/power assignments.
maintain	Maintains existing channel assignments.
multi-band	Computes ARM assignments for both 5 GHZ (802.11a) and 2.4 GHZ (802.11b/g) frequency bands.
single-band	Computes ARM assignments for a single band.
backoff-time	Time, in seconds, an AP backs off after requesting a new channel or power. 120-3600 240 sec
channel-quality-aware-arm	If enabled, ARM changes are based upon an internally calculated channel quality metric. When this feature is disabled, ARM initiates channel changes based on thresholds defined in this profile, and chooses the channel based on the calculated interference index value. disabled
channel-quality-threshold	Channel quality percentage below which ARM initiates a channel change. 0-100 70
channel-quality-wait-time	If channel quality is below the specified channel quality threshold for this wait time period, ARM initiates a channel change. 1-3600 120
client-aware	If the Client Aware option is enabled, the AP does not change channels if there is active client traffic on that AP. If Client Aware is disabled, the AP may change to a more optimal channel, but this change may also disrupt current client traffic. enabled
client match	ClientMatch helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless client's probe requests.

Parameter	Description
	<p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP.</p> <p>enabled</p>
clone	Name of an existing ARM profile from which parameter values are copied.
cm-6ghz-band-steer	Enable or disable Client Match band steers to 6GHz.
cm-band-a-min-signal <cm-band-a-min-signal>	<p>Minimum signal level required for the targeted A band radio in a Client Match band steer move (-dBm).</p> <p>0-255 dbm</p> <p>75</p>
cm-band-g-max-signal <cm-band-g-max-signal>	<p>Maximum signal level of the G band radio that can trigger a Client Match band steer move (-dBm)</p> <p>0-255 dbm</p> <p>45</p>
cm-dot11v	<p>Client Match steers using 802.11v BSS Transition Management.</p> <p>enabled</p>
cm-he-min-signal	<p>Minimum signal required for the targeted HE move (-dbm).</p> <p>0-255 dbm</p> <p>55</p>
cm-he-pooling-signal-delta	Target radio should not have weaker signal strength than current source radio by the configured value.
cm-he-pooling-snr-thresh	Client match HE pooling SNR threshold (dB) at target radio
cm-lb-client-thresh <#-of-clients>	<p>If an AP radio has fewer clients than the client match load balancing threshold defined by this parameter, the AP will not participate in load balancing.</p> <p>0-100 clients</p> <p>30</p>

Parameter	Description
cm-lb-interval <cm-lb-interval>	<p>Controls how often client load balancing will be done (in minutes). Set to 0 to disable Load Balancing.</p> <p>0-255 minutes 5 minutes</p>
cm-lb-signal-delta	<p>Client match will not move a client to a new radio if the signal strength of the target AP is this dB value lower than the radio to which the client is currently associated. This parameter works differently than the cm-lb-snr-thresh value, which imposes a definite value on the target AP's signal-to-noise ratio. the cm-lb-signal-delta imposes a <i>relative</i> constraint based upon the signal strength of the radio to which the client is currently associated.</p> <p>0-20 dB 5 dB</p>
cm-lb-snr-thresh <dB>	<p>Clients must detect a SNR from an underutilized AP radio at or above this threshold before ClientMatch considers load balancing a client to that radio.</p> <p>0-100 dB 25</p>
cm-lb-thresh <%-of-clients>	<p>When ClientMatch is enabled, clients may be steered from a highly utilized channel on an AP to a channel with fewer clients. If a channel on an AP radio has this percentage fewer clients than another channel supported by the client, ClientMatch may move clients from the busier channel to the channel with fewer clients.</p> <p>0-100% 20</p>
cm-max-steer-fails <#-of-fails>	<p>The controller keeps track of the number of times ClientMatch failed to steer a client to a different radio, and the reason that each steer attempt was triggered. If ClientMatch attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as unsteerable for that specific trigger.</p> <p>This parameter defines the maximum allowed number of client match steering fails with the same trigger before the client is marked as unsteerable for that trigger.</p> <p>0-100 failures 5</p>

Parameter	Description
cm-mu-client-thresh <count>	<p>Total number of clients that can be associated to a radio, in which the radio can still be considered for multi-user (MU) steering.</p> <p>0-255 dbm</p> <p>15</p>
cm-mu-snr-thresh <value>	<p>Minimum SNR value of a client on the target radio, in which the radio can still be considered for multi-user (MU) steering.</p> <p>0-255 dbm</p> <p>30</p>
cm-report-interval <secs>	<p>This interval defines how often an AP sends an updated client probe report to the controller. Each client probe report contains a list of MAC addresses for clients that have been active in the last two minutes, and the AP radio SNR values seen by those clients.</p> <p>0-255 secs</p> <p>30</p>
cm-stale-age <secs>	<p>The controller can maintain client match data for the maximum number of supported clients for that controller platform, showing the detected SNR values for up to 16 candidate APs per client. This table is periodically updated as APs send client probe reports to the controller. This parameter defines the amount of time that the controller should retain client match data from each client probe report.</p> <p>Different controller types support varying numbers of clients.</p> <ul style="list-style-type: none"> ■ 7005: 1024 client ■ 7010: 2048 clients ■ 7030: 4096 clients ■ 7240: 32000 clients ■ 7220: 24000 clients ■ 7210: 16000 clients <p>0- 65535 seconds</p> <p>120 seconds</p>
cm-steer-backoff	<p>Client Match will attempt one IOS steer at the configured backoff time interval.</p>
cm-steer-timeout	<p>When a client is steered from one AP to a more desirable AP, the steer timeout feature helps facilitate the move by defining the amount of time that any APs to which the client should NOT associate will not respond to the AP.</p>

Parameter	Description
	0-255 seconds
cm-sticky-check-interval <secs>	Frequency at which the AP checks for client's received SNR values. If the SNR value drops below the threshold defined by the <code>cm-sticky-snr</code> parameter for three consecutive check intervals, that client may be moved to an different AP. 0-255 seconds 3 seconds
cm-sticky-min-signal <-dB>	A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the candidate AP radio is at or higher than the minimum signal level defined by this parameter <i>and</i> the candidate radio has a higher signal strength than the radio to which the client is currently associated. (The required improvement in signal strength can be defined using the <code>cm-sticky-snr-delta</code> command.) 0-255 (-dB) 65
cm-sticky-snr <dB>	If the client's received signal strength indicator (RSSI) is above this signal-to-noise ratio (SNR) threshold, that client will be allowed to stay associated to its current AP. If the client's received signal strength is below this threshold, it may be moved to a different AP. 0-255 dB
cm-sticky-snr-delta	A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the AP radio is stronger than its current radio by the dB level defined by the <code>cm-sticky-snr-thresh</code> parameter, and the candidate radio also has a minimum signal level defined by the <code>cm-sticky-min-signal</code> parameter. 0-100 dB 10
cm-unst-ageout-interval days <days>	The client entries in an unsteerable client list remain in effect for the interval defined by this parameter before they age out. 2 days

Parameter	Description
cm-unst-ageout	<p>When client match and the client match unsteerable client ageout feature are enabled, the controller periodically sends APs that are not a desired AP match for a client in a list of unsteerable clients. These lists contain a list of MAC addresses for up to 128 clients that should not be steered to that AP. The following controller types support a aggregate maximum of unsteerable clients for all APs associated to that controller.</p> <ul style="list-style-type: none"> ■ 7005: 256 unsteerable clients ■ 7010: 512 unsteerable clients ■ 7030: 1024 unsteerable clients ■ 7240: 8000 unsteerable clients ■ 7220: 6000 unsteerable clients ■ 7210: 4000 unsteerable clients
default-6ghz	<p>Configures the ARM default-6 GHz profile. For more information, see rf arm-profile default-6ghz.</p>
dynamic-bw	<p>Issue the <code>dynamic-bw</code> parameter to enable the ARM dynamic bandwidth switch feature. When enabled ARM can detect 20MHz interferers that can impact an AP radio using an 80MHz channel and move the AP radio to another 80MHz channel. For more information, see 80 MHz Dynamic Bandwidth Switch on page 1165</p> <p>disabled</p>
dynamic-bw-beacon-failed-thresh	<p>The ARM dynamic bandwidth switch feature may trigger a change in the radio channel bandwidth if the number of failed beacons exceeds this value during the observation window.</p> <p>1-500 30</p>
dynamic-bw-cca-ibss-thresh	<p>The ARM dynamic bandwidth switch feature may trigger a change in the radio channel bandwidth if the clear channel assignment IBSS percentage drops below this value during the observation window.</p> <p>1-100 10</p>
dynamic-bw-cca-intf-thresh	<p>The ARM dynamic bandwidth switch feature may trigger a change in the radio channel bandwidth if the clear channel assignment interference percentage exceeds this value during the observation window.</p> <p>1-100 30</p>

Parameter	Description
dynamic-bw-clear-time	<p>The ARM dynamic bandwidth switch feature returns the AP radio to 80MHz channel after this clear time period if there is no high volume of traffic.</p> <p>1-300 seconds</p> <p>30</p>
dynamic-bw-wait-time	<p>Minimum time in seconds dynamic bandwidth switch indicators have to be true to trigger a 80MHz to 40MHz bandwidth change.</p> <p>1-300 seconds</p> <p>30</p>
error-rate-threshold	<p>The percentage of errors in the channel that triggers a channel change. Recommended value is 50%. A value of 0% disables this feature.</p> <p>0-100</p> <p>default-a: 70%, default-g: 70%</p>
error-rate-wait-time	<p>Time, in seconds, that the error rate has to be at least the error rate threshold to trigger a channel change. Recommended values are 1-100.</p> <p>1-2,147,483,647</p> <p>default-a: 90 seconds, default-g: 90 seconds</p>
free-channel-index	<p>The difference in the interference index between the new channel and current channel must exceed this value for the AP to move to a new channel. The higher this value, the lower the chance an AP will move to the new channel. Recommended value is 25.</p> <p>10-40</p> <p>default-a: 40, default-g: 25</p>
high-noise-backoff-time	<p>The duration, in minutes, for blacklisting/denylisting AirMatch Solver's channel after 2 consecutive high noise detections. Setting the value to 0 disables the backoff window.</p> <p>0-3600</p> <p>720 minutes (12 hours)</p>
ideal-coverage-index	<p>The coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be. Recommended value is 10.</p> <p>2-20</p> <p>default-a: 6, default-g: 6</p>

Parameter	Description
load-aware-scan-threshold	<p>Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high. The Load Aware Scan Threshold is the traffic throughput level an AP must reach before it stops scanning. The supported range for this setting is 0-20000000 bytes/second. (Specify 0 to disable this feature.)</p> <p>1250000 bytes/second</p>
max-tx-power	<p>Maximum effective isotropic radiated power (EIRP) from 3 to 33 dBm in 3 dBm increments. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links. This value takes into account both radio transmit power and antenna gain. Higher power level settings may be constrained by local regulatory requirements and AP capabilities.</p> <p>3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33, 127</p> <p>default-a: 18 dBm, default-g: 9 dBm</p>
min-scan-time	<p>Minimum number of times a channel must be scanned before it is considered for assignment. The supported range for this setting is 0-2,147,483,647 scans. Best practices are to configure Minimum Scan Time between 1-20 scans. Recommended values are 1-20.</p> <p>1-2,147,483,647</p> <p>8 scans</p>
min-tx-power	<p>Minimum effective isotropic radiated power (EIRP) from 3 to 33 dBm in 3 dBm increments. You may also specify a special value of 127 dBm for regulatory minimum. This value takes into account both radio transmit power and antenna gain. Higher power level settings may be constrained by local regulatory requirements and AP capabilities.</p> <p>3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33, 127</p> <p>default-a: 12 dBm, default-g: 6 dBm</p>
mode-aware	<p>If enabled, ARM will turn APs into Air Monitors (AMs) if it detects higher coverage levels than necessary. This helps avoid higher levels of interference on the WLAN. Although this setting is disabled by default, you may want to enable this feature if your APs are deployed in close proximity (e.g. less than 60 feet apart).</p> <p>disabled</p>

Parameter	Description
multi-band-scan	When enabled, single-radio APs try to scan across bands for rogue AP detection. enabled
no	Negates any configured parameter.
ota-updates	The ota-updates option allows an AP to get information about its RF environment from its neighbors, even the AP cannot scan. If this feature is enabled, when an AP on the network scans a foreign (non-home) channel, it sends other APs an Over-the-Air (OTA) update in an 802.11 management frame that contains information about the scanning AP's home channel, the current transmission EIRP value of its home channel, and one-hop neighbors seen by that AP. enabled
ps-aware-scan	When enabled, the AP will not scan if Power Save is active. disabled
radar-backoff-time	The duration, in minutes, for blacklisting/denylisting AirMatch solver's channel after 2 consecutive radar detections. Setting the value to 0 disables the backoff window. 0-3600 720 minutes (12 hours)
rogue-ap-aware	When enabled, the AP will try to contain off-channel rogue APs. disabled
scan-interval	If scanning is enabled, the scan interval defines how often the AP will leave its current channel to scan other channels in the band. Off-channel scanning can impact client performance. Typically, the shorter the scan interval, the higher the impact on performance. If you are deploying a large number of new APs on the network, you may want to lower the Scan Interval to help those APs find their optimal settings more quickly. Raise the Scan Interval back to its default setting after the APs are functioning as desired. Recommended values are 0-30 seconds. 0-2,147,483, 647 seconds 10 seconds
scan-mode	Select the scan mode for the AP: <ul style="list-style-type: none"> ■ all-reg-domain: The AP scans channels within

Parameter	Description
	<p>all regulatory domains. This is the default setting.</p> <ul style="list-style-type: none"> ■ reg-domain: Limit the AP scans to just the regulatory domain for that AP. <p>all-reg-domain</p>
scanning	<p>The Scanning check box enables or disables AP scanning across multiple channels. Disabling this option also disables the following scanning features:</p> <ul style="list-style-type: none"> ■ Multi Band Scan ■ Rogue AP Aware ■ Voip Aware Scan ■ Power Save Scan <p>Do not disable Scanning unless you want to disable ARM and manually configure AP channel and transmission power.</p> <p>enabled</p>
video-aware-scan	<p>As long as there is at least one video frame every 100 mSec the AP will reject an ARM scanning request. Note that for each radio interface, video frames must be defined in one of two ways:</p> <ul style="list-style-type: none"> ■ Classify the frame as video traffic via a session ACL. ■ Enable WMM on the WLAN's SSID profile and define a specific DSCP value as a video stream. Next, create a session ACL to tag the video traffic with the that DSCP value. <p>enabled</p>
voip-aware-scan	<p>Aruba's VoIP Intelligent Call Handling (ICH) prevents any single AP from becoming congested with voice calls. When you enable ICH, you should also enable voip-aware-scan parameter in the ARM profile, so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that scanning is also enabled.</p> <p>disabled</p>
voip-aware-scan-timer	<p>When enabled, the AP will not scan if the scan request falls within the scan timer of the last voice frame. Range is 50 ms—1000 ms.</p> <p>Default: 50 ms</p>

Default Profiles

ArubaOS includes two default ARM profiles, **default-a** for 5 Ghz radios, and **default-g** for 2.4 GHz radios.

Channel Quality

Hybrid APs and Spectrum Monitors determine channel quality by measuring channel noise, non-Wi-Fi (interferer) utilization and duty-cycles, and certain types of Wi-Fi retries. Regular APs using ARM derive channel quality values by measuring the noise floor for that channel.

Client Match

The ARM client match feature continually monitors a client's RF neighborhood to provide ongoing client bandsteering and load balancing, and enhanced AP reassignment for roaming mobile clients. This feature is recommended over the legacy bandsteering and spectrum load balancing features, which, unlike client match, do not trigger AP changes for clients already associated to an AP.

Legacy 802.11a/b/g devices do not support ClientMatch. When client match is enabled on 802.11n-capable devices, ClientMatch overrides any settings configured for the legacy bandsteering, station handoff assist or load balancing features. 802.11ac-capable devices do not support the legacy bandsteering, station hand off or load balancing settings, so these APs must be managed on using client match.

When this feature is enabled on an AP, that AP is responsible for measuring the RF health of its associated clients. The AP receives and collects information about clients in its neighborhood, and periodically sends this information to the controller. The controller aggregates and maintains a database of information about AP transmit power levels, client transmit power levels and AP RSSI levels as seen by clients. The controller shares this database with the APs (for their associated clients) and the APs use the information to compute the client-based RF neighborhood and determine which APs should be considered candidate APs for each client. When the controller receives a client steer request from an AP, the controller identifies the optimal AP candidate and manages the client's relocation to the desired radio. This is an improvement from previous releases, where ARM was managed exclusively by APs, the without the larger perspective of the client's RF neighborhood.

The following client/AP mismatch conditions are managed by ClientMatch:

Load Balancing: Client match balances clients across APs on different channels, based upon the client load on the APs and the SNR levels the client detects from an underutilized AP. If an AP radio can support additional clients, the AP will participate in client match load balancing and clients can be directed to that AP radio, subject to predefined SNR thresholds.

Sticky Clients: ClientMatch also helps mobile clients that tend to stay associated to an AP despite low signal levels. APs using client match continually monitor the client's RSSI as it roams between APs, and move the client to an AP when a better radio match can be found. This prevents mobile clients from remaining associated to an APs with less than ideal RSSI, which can cause poor connectivity and reduce performance for other clients associated with that AP.

Band Steering/Band Balancing: APs using ClientMatch monitor the RSSI for clients that advertise a dual-band capability. If a client is currently associated to a 2.4 GHz radio and the AP detects that the client has a good RSSI from the 5 GHz radio, the controller will attempt to steer the client to the 5 GHz radio, as long as the 5 GHz RSSI is not significantly worse than the 2.4 GHz RSSI, and the AP retains a suitable distribution of clients on each of its radios.

■E Steering: 802.11ax clients are best compatible with 802.11ax capable radios, resulting in better throughput and spectral efficiency. When an 802.11ax client is associated with a lower radio, ClientMatch pushes the client to the best compatible 802.11ax radio for advanced capabilities. Though STA is in good health, and is 802.11ax capable, it still sometimes connects to lower radios. ClientMatch finds a potential 802.11ax radio on the same band and the client moves to the new 802.11ax radio.

80 MHz Dynamic Bandwidth Switch

If an AP radio uses an 80 MHz channel, the radio only sends out frames out when the entire 80 MHz channel is clear, even if the AP is sending only a 20 MHz management frame or 40MHz data frame. As a result, throughput on the selected 80 MHz channel can be negatively impacted if interference occurs on both 20 MHz channels of the secondary 40MHz channel.

The ARM dynamic bandwidth switch feature allows ARM to detect the 20MHz interferers in this situation, and potentially move the AP radio to another 80MHz channel, or change the AP transmissions to 40MHz, and use the primary 40MHz channel instead.

When this feature is enabled, ARM starts a dynamic bandwidth switch observation window if load-aware scan rejects increase, *and* the clear channel assignment IBSS percentage (the percentage of channel traffic sent from that AP radio) drops below the value defined by the `dynamic-bw-cca-ibss-thresh` parameter.

If an observation window opens, and the clear channel assignment interference threshold exceeds the value defined by the `dynamic-bw-cca-intf-thresh` parameter, and the number of failed beacons from the radio exceeds the threshold defined by the `dynamic-bw-beacon-failed-thresh` parameter during that observation period, ARM will move the AP to another available 80MHz channel with the minimum interference index. If no other 80MHz channel is available, ARM downgrades the radio bandwidth to 40MHz.

ARM Scanning

The default ARM scanning interval is determined by the `scan-interval` parameter in the ARM profile. If the AP does not have any associated clients (or if most of its clients are inactive) ARM will dynamically readjust this default scan interval, allowing the AP obtain better information about its RF neighborhood by scanning non-home channels more frequently. If an AP attempts to scan a non-home channel but is unsuccessful, the AP will make additional attempts to rescan that channel before skipping it and continuing on to other channels.

Using Adaptive Radio Management (ARM) in a Mesh Network

When a mesh portal operates on a mesh network, the mesh portal determines the channel used by the mesh feature. When a mesh point locates an upstream mesh portal, it will scan the regulatory domain channels list to determine the channel assigned to it, for a mesh point always uses the channel selected by its mesh portal. However, if a mesh portal uses an ARM profile enabled with a single-band or multi-band channel/power assignment and the scanning feature, the mesh portal will scan the configured channel lists and the ARM algorithm will assign the proper channel to the mesh portal.

If you are using ARM in your network, it is important to note that mesh points, unlike mesh portals, do not scan channels. This means that once a mesh point has selected a mesh portal or an upstream mesh point, it will tune to this channel, form the link, and will not scan again unless the mesh link gets broken. This provides good mesh link stability, but may adversely affect system throughput in networks with mesh portals and mesh points. When ARM assigns optimal channels to mesh portals, those portals use different channels, and once the mesh network has formed and all the mesh points have selected a portal (or upstream mesh point), those mesh points will not be able to detect other portals on other channels that could offer better throughput. This type of suboptimal mesh network may form if, for example, two or three mesh points select the same mesh portal after booting, form the mesh network, and leave a nearby mesh portal without any mesh points. Again, this will not affect mesh functionality, but may affect total system throughput.

Example

The following command configures VoIP-aware scanning for the arm-profile named "voice-arm:"

```
(host) [mynode] (config) #rf arm-profile voice-arm
                        voip-aware-scan
```

Command History

Release	Modification
ArubaOS 8.9.0.0	The <code>default-6ghz</code> parameter was added.
ArubaOS 8.8.0.0	The <code>voip-aware-scan-timer</code> parameter was added.
ArubaOS 8.7.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>cm-he-pooling-signal-delta</code> ■ <code>cm-he-pooling-snr-thresh</code>
ArubaOS 8.5.0.0	The <code>cm-he-min-signal</code> parameter was added.
ArubaOS 8.2.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>high-noise-backoff-time</code> ■ <code>radar-backoff-time</code>
ArubaOS 8.0.0.0	Command introduced.

Description

This command configures the Adaptive Radio Management (ARM) default-6 GHz profile. Adaptive Radio Management (ARM) is a radio frequency (RF) resource allocation algorithm that allows each

AP to determine the optimum channel selection and transmit power setting to minimize interference and maximize coverage and throughput. This command configures an ARM profile that you apply to a default-6 GHz radio profile.

Parameter	Description
160MHz support Auto Contiguous-only Non-contiguous-only None	Specifies which 160 MHz mode is assigned. Does not apply to the 2.4 GHz radio. Default: None
40MHz-allowed-bands 2.4GHz-and-5GHz 2.4GHz-and-6GHz 5GHz-and-6GHz 6GHz-only a-only All g-only none	Specifies on which bands (802.11a or 802.11g) the 40 MHz channels may be used: <ul style="list-style-type: none"> ■ 2.4GHz-and-5GHz: Allows the use of the 40 MHz channels on both 2.4 GHz and 5 GHz frequency band only. ■ 2.4GHz-and-6GHz: Allows the use of the 40 MHz channels on both 2.4 GHz and 6 GHz frequency band only. ■ 5GHz-and-6GHz: Allows the use of the 40 MHz channels on both 5 GHz and 6 GHz frequency band only. ■ 6GHz: Allows the use of the 40 MHz channels on the 6 GHz frequency band only. ■ A-only: Allows the use of the 40 MHz channels on the 5 GHz (802.11a) frequency band only. ■ All: Allows the 40 MHz channels on both the 5 GHz (802.11a) and 2.4 GHz (802.11b/g) frequency bands. ■ G-only: Allows the use of the 40 MHz channels on the 2.4 GHz (802.11b/g) frequency band only. ■ None: Disallows the use of the 40 MHz channels Default: a-only
80MHz support	If enabled, the 80 MHz channels are used on the 5 GHz radio. Does not apply to the 2.4 GHz radio. Default: Enabled
acceptable-coverage-index	The minimal coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be. This setting applies to multi-band implementations only.
active-scan	When active-scan is enabled, an AP initiates active scanning via probe request. This option elicits more information from nearby APs, but also creates additional management traffic on the network. This feature is disabled by default, and should <i>not be enabled</i> except under the direct supervision of Aruba Technical Support.

Parameter	Description
	Default: Disabled
aggressive-scan	If enabled, an AP radio with no clients will scan channels every second. Default: Enabled
assignment disable maintain multi-band single-band	Specify one of four ARM channel/power assignment modes: Disable: Disable ARM channel/power assignments. Maintain: Maintain existing channel assignments. Single-band: Compute ARM assignments for a single band. Multi-band: Compute ARM assignments for both 5 GHZ (802.11a) and 2.4 GHZ (802.11b/g) frequency bands. Default: Single-band
backoff-time	Time, in seconds, when an AP backs off after requesting a new channel or power. Range: 120-3600 Default: 240
channel-quality-aware-arm	If enabled, ARM changes are based upon an internally calculated channel quality metric. When this feature is disabled, ARM initiates channel changes based on thresholds defined in this profile, and chooses the channel based on the calculated interference index value. Default: Disabled
channel-quality-threshold	Channel quality percentage below which ARM initiates a channel change. Range: 0-100 Default: 70
channel-quality-wait-time	If channel quality is below the specified channel quality threshold for this wait time period, ARM initiates a channel change. Range: 1-3600 Default: 120
client-aware	If the Client Aware option is enabled, the AP does not change channels if there is active client traffic on that AP. If Client Aware is disabled, the AP may change to a more optimal channel, but this change may also disrupt current client traffic. Default: Enabled
client-match	ClientMatch helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless client's probe requests.

Parameter	Description
	If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP.
clone	Name of an existing ARM profile from which parameter values are copied.
cm-6ghz-band-steer	Enable Client Match band steers to the 6 GHz radio.
cm-band-a-min-signal	Minimum signal level required for the targeted A band radio in a Client Match band steer move (-dBm). Range: 0-255 dbm Default: 75
cm-band-g-max-signal	Maximum signal level of the G band radio that can trigger a Client Match band steer move (-dBm) Range: 0-255 dbm Default: 45
cm-dot11v	Client Match steers using 802.11v BSS Transition Management. Default: Enabled
cm-he-min-signal	Minimum signal required for the targeted HE move (-dbm). Range: 0-255 dbm Default: 55
cm-he-pooling-signal-delta	Target radio should not have weaker signal strength than current source radio by the configured value.
cm-he-pooling-snr-thresh	Client match HE pooling SNR threshold (dB) at target radio
cm-lb-client-thresh	If an AP radio has fewer clients than the client match load balancing threshold defined by this parameter, the AP will not participate in load balancing. Range: 0-100 Default: 30
cm-lb-interval	Specify, in minutes, how often client load balancing is performed. Range: 0-255 Default: 5

Parameter	Description
cm-lb-signal-delta	<p>Client match will not move a client to a new radio if the signal strength of the target AP is this dB value lower than the radio to which the client is currently associated. This parameter works differently than the cm-lb-snr-thresh value, which imposes a definite value on the target AP's signal-to-noise ratio. The cm-lb-signal-delta imposes a <i>relative</i> constraint based upon the signal strength of the radio to which the client is currently associated.</p> <p>Range: 0-20 Default: 5</p>
cm-lb-snr-thresh	<p>Clients must detect a SNR from an underutilized AP radio at or above this threshold before ClientMatch considers load balancing a client to that radio.</p> <p>Range: 0-100 Default: 25</p>
cm-lb-thresh	<p>Client Match load balancing client distribution threshold between channels, as a percentage of clients.</p>
cm-max-steer-fails	<p>The controller keeps track of the number of times ClientMatch failed to steer a client to a different radio, and the reason that each steer attempt was triggered. If ClientMatch attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as unsteerable for that specific trigger. This parameter defines the maximum allowed number of client match steering fails with the same trigger before the client is marked as unsteerable for that trigger.</p> <p>Range: 0-100 Default: 5</p>
cm-mu-client-thresh	<p>Total number of clients that can be associated to a radio, in which the radio can still be considered for multi-user (MU) steering.</p> <p>Range: 0-255 Default: 15</p>
cm-mu-snr-thresh	<p>Minimum SNR value of a client on the target radio, in which the radio can still be considered for multi-user (MU) steering.</p> <p>Range: 0-255 Default: 30</p>
cm-report-interval	<p>This interval defines how often an AP sends an updated client probe report to the controller. Each client probe report contains a list of MAC addresses for clients that have been active in the last two minutes, and the AP radio SNR values seen by those clients.</p> <p>Range: 0-255 Default: 30</p>

Parameter	Description
cm-stale-age	<p>The controller can maintain client match data for the maximum number of supported clients for that controller platform, showing the detected SNR values for up to 16 candidate APs per client. This table is periodically updated as APs send client probe reports to the controller. This parameter defines the amount of time, in seconds, that the controller should retain client match data from each client probe report.</p> <p>Different controller types support varying numbers of clients.</p> <ul style="list-style-type: none"> ■ 7005: 1024 client ■ 7010: 2048 clients ■ 7030: 4096 clients ■ 7240: 32000 clients ■ 7220: 24000 clients ■ 7210: 16000 clients <p>Range: 0-65535 Default: 120 seconds</p>
cm-steer-backoff	<p>Client Match will attempt one IOS steer at the configured backoff time interval.</p>
cm-steer-timeout	<p>When a client is steered from one AP to a more desirable AP, the steer timeout feature helps facilitate the move by defining the amount of time that any APs to which the client should NOT associate will not respond to the AP.</p> <p>Range: 0-255</p>
cm-sticky-check-interval	<p>Frequency at which the AP checks for client's received SNR values. If the SNR value drops below the threshold defined by the <code>cm-sticky-snr</code> parameter for three consecutive check intervals, that client may be moved to an different AP.</p> <p>Range: 0-255 Default: 3</p>
cm-sticky-min-signal	<p>A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the candidate AP radio is at or higher than the minimum signal level defined by this parameter <i>and</i> the candidate radio has a higher signal strength than the radio to which the client is currently associated. (The required improvement in signal strength can be defined using the <code>cm-sticky-snr-delta</code> command.)</p> <p>Range: 0-255 Default: 65</p>
cm-sticky-snr	<p>If the client's received signal strength indicator (RSSI) is above this signal-to-noise ratio (SNR) threshold, that client will be allowed to stay associated to its current AP. If the client's received signal strength is below this threshold, it may be moved to a different AP.</p>

Parameter	Description
	Range: 0-255
cm-sticky-snr-delta	<p>A client triggered to move to a different AP may consider an AP radio a better match if the client detects that the signal from the AP radio is stronger than its current radio by the dB level defined by the cm-sticky-snr-thresh parameter, and the candidate radio also has a minimum signal level defined by the cm-sticky-min-signal parameter.</p> <p>Range: 0-100 Default: 10</p>
cm-unst-ageout-intvl days	<p>The client entries in an unsteerable client list remain in effect for the interval, in days and hours, defined by this parameter before they age out.</p> <p>Range: 2</p>
cm-unst-ageout	<p>When client match and the client match unsteerable client ageout feature are enabled, the controller periodically sends APs that are not a desired AP match for a client in a list of unsteerable clients. These lists contain a list of MAC addresses for up to 128 clients that should not be steered to that AP.</p> <p>The following controller types support a aggregate maximum of unsteerable clients for all APs associated to that controller.</p> <ul style="list-style-type: none"> ■ 7005: 256 unsteerable clients ■ 7010: 512 unsteerable clients ■ 7030: 1024 unsteerable clients ■ 7240: 8000 unsteerable clients ■ 7220: 6000 unsteerable clients ■ 7210: 4000 unsteerable clients
dynamic-bw	<p>Issue the dynamic-bw parameter to enable the ARM dynamic bandwidth switch feature. When enabled ARM can detect 20 MHz interferers that can impact an AP radio using an 80 MHz channel and move the AP radio to another 80 MHz channel. For more information, see rf arm-profile default-6ghz on page 1167</p> <p>Default: Disabled</p>
dynamic-bw-beacon-failed-thresh	<p>The ARM dynamic bandwidth switch feature may trigger a change in the radio channel bandwidth if the number of failed beacons exceeds this value during the observation window.</p> <p>Range: 1-500 Default: 30</p>
dynamic-bw-cca-ibss-thresh	<p>The ARM dynamic bandwidth switch feature may trigger a change in the radio channel bandwidth if the clear channel assignment IBSS percentage drops below this value during the observation window.</p> <p>Range: 1-100</p>

Parameter	Description
	Default: 10
dynamic-bw-cca-intf-thresh	The ARM dynamic bandwidth switch feature may trigger a change in the radio channel bandwidth if the clear channel assignment interference percentage exceeds this value during the observation window. Range: 1-100 Default: 30
dynamic-bw-clear-time	The ARM dynamic bandwidth switch feature returns the AP radio to 80 MHz channel after this clear time period , in seconds, if there is no high volume of traffic. Range: 1-300 Default: 30
dynamic-bw-wait-time	Minimum time in seconds dynamic bandwidth switch indicators have to be true to trigger a 80 MHz to 40MHz bandwidth change. Range: 1-300 Default: 30
error-rate-threshold	The percentage of errors in the channel that triggers a channel change. Recommended value is 50%. A value of 0% disables this feature. Range: 0-100 Default: 70
error-rate-wait-time	Time, in seconds, that the error rate has to be at least the error rate threshold to trigger a channel change. Recommended values are 1-100. Default: 90
free-channel-index	The difference in the interference index between the new channel and current channel must exceed this value for the AP to move to a new channel. The higher this value, the lower the chance an AP will move to the new channel. Recommended value is 25. Range: 10-40 Default: 40
gateway	Specify the default gateway to use.
geolocation	Specify the geographical location of the device.
gsm	Specify the GSM related tracing.
guest-access-email	Specify the guest-access email profile.
ideal-coverage-index	The coverage that the AP should try to achieve on its channel. The denser the AP deployment, the lower this value should be. Recommended value is 10. Range: 2-20

Parameter	Description
	Default: 6
<code>interfering-ap-weight</code>	The weight of the interfering APs in interference index calculation. Range: 0-100 Default: 25
<code>load-aware-scan-threshold</code>	Load aware ARM preserves network resources during periods of high traffic by temporarily halting ARM scanning if the load for the AP gets too high. The Load Aware Scan Threshold is the traffic throughput level an AP must reach before it stops scanning. The supported range for this setting is 0-20000000 bytes/second. (Specify 0 to disable this feature.) Range: 1250000 bytes/second
<code>max-tx-power</code>	Maximum effective isotropic radiated power (EIRP) from 3 to 33 dBm in 3 dBm increments. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links. This value takes into account both radio transmit power and antenna gain. Higher power level settings may be constrained by local regulatory requirements and AP capabilities. Range: 3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33, 127 Default: 18
<code>min-scan-time</code>	Minimum number of times a channel must be scanned before it is considered for assignment. The supported range for this setting is 0-2,147,483,647 scans. Best practices are to configure Minimum Scan Time between 1-20 scans. Range: 1-20. Default: 8
<code>min-tx-power</code>	Minimum effective isotropic radiated power (EIRP) from 3 to 33 dBm in 3 dBm increments. You may also specify a special value of 127 dBm for regulatory minimum. This value takes into account both radio transmit power and antenna gain. Higher power level settings may be constrained by local regulatory requirements and AP capabilities. Range: 3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33, 127 Default: 12
<code>mode-aware</code>	If enabled, ARM will turn APs into Air Monitors (AMs) if it detects higher coverage levels than necessary. This helps avoid higher levels of interference on the WLAN. Although this setting is disabled by default, you may want to enable this feature if your APs are deployed in close proximity (e.g. less than 60 feet apart). Default: Disabled

Parameter	Description
multi-band-scan	When enabled, single-radio APs try to scan across bands for rogue AP detection. Default: Enabled
no	Negates any configured parameter.
ota-updates	The ota-updates option allows an AP to get information about its RF environment from its neighbors, even the AP cannot scan. If this feature is enabled, when an AP on the network scans a foreign (non-home) channel, it sends other APs an Over-the-Air (OTA) update in an 802.11 management frame that contains information about the scanning AP's home channel, the current transmission EIRP value of its home channel, and one-hop neighbors seen by that AP. Default: Enabled
ps-aware-scan	When enabled, the AP will not scan if Power Save is active. Default: Disabled
rogue-ap-aware	When enabled, the AP will try to contain off-channel rogue APs. Default: Disabled
scan-interval	If scanning is enabled, the scan interval defines how often the AP will leave its current channel to scan other channels in the band. Off-channel scanning can impact client performance. Typically, the shorter the scan interval, the higher the impact on performance. If you are deploying a large number of new APs on the network, you may want to lower the Scan Interval to help those APs find their optimal settings more quickly. Raise the Scan Interval back to its default setting after the APs are functioning as desired. Range: 0-30 Default: 10
scan-mode	Select the scan mode for the AP: <ul style="list-style-type: none"> ■ all-reg-domain: The AP scans channels within all regulatory domains. This is the default setting. ■ reg-domain: Limit the AP scans to just the regulatory domain for that AP. Default: All-reg-domain
scanning	The Scanning check box enables or disables AP scanning across multiple channels. Disabling this option also disables the following scanning features: <ul style="list-style-type: none"> ■ Multi Band Scan ■ Rogue AP Aware ■ Voip Aware Scan ■ Power Save Scan

Parameter	Description
	Do not disable Scanning unless you want to disable ARM and manually configure AP channel and transmission power. Default: Enabled
telnet	Enable the telnet port.
threshold	Specify the threshold.
time-range	Specify the time range.
time-range-profile	Specify the time range profile.
traceoptions	Specify the trace options.
tunnel-group	Specify the tunnel group.
tunnel-loop-prevention	Prevent forwarding loops between the tunnels from the tunneled nodes on the managed device.
tunnel-node-mtu	Specify the MTU for the tunneled node.
tunneled-node-address	Specify the IP address of the managed device to terminate the tunnels. An IP address of th 0.0.0.0 disables the configuration.
ucc	Specify the UCC configuration.
upgrade-profile	Specify the upgrade profile.
uplink	Specify the uplink manager configuration.
user-role	Specify the user role.
video-aware-scan	As long as there is at least one video frame every 100 mSec the AP will reject an ARM scanning request. Note that for each radio interface, video frames must be defined in one of two ways: <ul style="list-style-type: none"> ■ Classify the frame as video traffic via a session ACL. ■ Enable WMM on the WLAN's SSID profile and define a specific DSCP value as a video stream. Next, create a session ACL to tag the video traffic with the that DSCP value. Default: Enabled

Parameter	Description
voip-aware-scan	Aruba's VoIP Intelligent Call Handling (ICH) prevents any single AP from becoming congested with voice calls. When you enable ICH, you should also enable voip-aware-scan parameter in the ARM profile, so the AP will not attempt to scan a different channel if one of its clients has an active VoIP call. This option requires that scanning is also enabled. Default: Disabled
voip-aware-scan-timer	When enabled, the AP will not scan if the scan request falls within the scan timer, in milliseconds, of the last voice frame. Range: 50-1000 Default: 50

Example

The following command configures VoIP-aware scanning for the arm-profile named "voice-arm:"

```
(host) [mynode] (config) #rf arm-profile default-6ghz
```

Description

This command configures the radio settings for a 802.11 6 GHz radio profile in the applicable access points. Each 6 GHz radio profile includes a reference to an ARM profile, high-throughput radio profile, and RRM IE radio profile. Channels must be valid for the country configured in the AP regulatory domain profile (see [ap regulatory-domain-profile on page 341](#)). To view the supported channels, use the `show ap allowed-channels` command.

Parameter	Description
6ghz-advertise-ap-name	Allows the 6 GHz radios, which are part of the virtual AP, to broadcast the AP name information in the beacon frames.
6ghz-dot11k-enable	Enables 802.11k capability for 6 GHz radio.
6ghz-mbo-enable	Enables Agile Multiband (MBO) for 6 GHz radio. Also enables mfp-capable, 802.11k and 802.11u interworking implicitly on the AP.
6ghz-rrm-ie-profile <profile-name>	Configures a Radio Resource Management (RRM) Information Elements (IE) profile to define the information elements advertised by a Wi-Fi 6E AP for 6 GHz band.
advertise-location-6ghz	Enables all 6 GHz virtual APs to broadcast their GPS coordinates in the beacon and probe response frames.
am-scan-profile <profile-name>	Configures an Air Monitor (AM) scanning profile for the various channels on 6 GHz radio.
arm-profile <profile-name>	Configures an Adaptive Radio Management (ARM) profile that is applied to a radio profile for the 6 GHz frequency band.
assoc-boost	Increases the client association success rate, especially in a noisy environment. When this parameter is enabled: <ul style="list-style-type: none"> ■ The management frame retransmission retry limit in the radio

Parameter	Description
	<p>firmware for both authentication and association response is increased, thereby increasing the management frame retransmission rate.</p> <ul style="list-style-type: none"> ■ If the management frame retransmission retry limit is reached, another round of management frames are scheduled after a short time delay. ■ If a client starts an association (by sending a probe or authentication request), AP scanning is rejected for 5 seconds, thereby not missing the client association request.
<code>basic-rates-6ghz {12 18 24 36 48 54 6 9}</code>	<p>Selects the basic rates for 6 GHz radio. The available values are 6, 9, 12, 18, 24, 36, 48, 54.</p>
<code>beacon-period <beacon-period></code>	<p>Configures the beacon period for the AP in msec.</p> <p>Range: 60-1000 msec</p> <p>Default: 100 msec</p>
<code>beacon-rate-6ghz {12 18 24 36 48 54 6 9 default}</code>	<p>Configures the beacon rate for 6 GHz radio. (For Distributed Antenna System (DAS) only).</p> <p>Default: Minimum valid rate</p>
<code>cap-reg-eirp <cap-reg-eirp></code>	<p>Workaround to override reg maximum EIRP in dot11d for interoperability with misbehaving clients.</p>

Parameter	Description
channel <channel>	<p>Channel number for the Wi-Fi 6E AP on 6 GHz radio band. The available channels depend on the regulatory domain (country). This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface. Channel number configuration options for 20 MHz, 40 MHz, and 80 Mhz modes:</p> <ul style="list-style-type: none">▪ num: Entering a channel number disables 40 MHz mode and activates 20 MHz mode for the entered channel.▪ num+: Entering a channel number with a plus (+) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by increasing the primary channel number by 4. Example: 157+ represents 157 as the primary channel and 161 as the secondary channel.▪ num-: Entering a channel number with

Parameter	Description
	<p>a minus (-) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by decreasing the primary channel number by 4. Example: 157- represents 157 as the primary channel and 153 as the secondary channel.</p> <p>NOTE: 20 MHz clients are allowed to associate when a primary and secondary channel are configured; however, the client will only use the primary channel.</p>
clone <source>	Name of an existing radio profile from which parameter values are copied.
csa	<p>Channel Switch Announcement (CSA), as defined by IEEE 802.11h, allows an AP to announce that it is switching to a new channel before it begins transmitting on that channel.</p> <p>Clients must support CSA in order to track the channel change without experiencing disruption.</p>

Parameter	Description
<code>csa-count <csa-count></code>	<p>Number of CSA announcements that are sent before the AP begins transmitting on the new channel.</p> <p>Range: 1-16</p> <p>Default: 4</p>
<code>deploy-hour</code>	<p>Configure hour-of-day for AP solution deployment. Overrides Airmatch profile if a valid hour is specified.</p> <p>Range: 0-23</p>
<code>disable-arm-wids-functions {Dynamic OFF ON}</code>	<p>Disables Adaptive Radio Management (ARM) and Wireless IDS functions. These can be disabled if a small increase in packet processing performance is desired. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled irrespective of this option.</p> <p>CAUTION: Use carefully, since this effectively disables ARM and WIDS.</p>
<code>disable-probe-retry-6ghz</code>	<p>Enables or disables battery MAC level retries for probe response frames.</p>
<code>dot11h</code>	<p>Enables advertisement of 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities</p>
<code>dynamic-frag-level-6ghz {Level-0 Level-1 Level-2 Level-3}</code>	<p>Configures the dynamic fragmentation level supported by the Wi-Fi 6E AP(only configurable in Bridge or D-tunnel mode):</p>

Parameter	Description
	<ul style="list-style-type: none"> ■ Level-0—Does not support dynamic fragmentation ■ Level-1—Supports dynamic fragments that are contained within a S-MPDU. Does not provide support for dynamic fragments within an A-MPDU that is not a S-MPDU. ■ Level-2—Supports dynamic fragments that are contained within a S-MPDU and support for up to one dynamic fragment for each MSDU within an A-MPDU. ■ Level-3—Supports dynamic fragments that are contained within a S-MPDU and support for up to four dynamic fragment for each MSDU within an A-MPDU. <p>Default: Level-0</p> <p>NOTE: This parameter is further limited by each AP's radio hardware capabilities.</p>
eirp-max	<p>Maximum EIRP. Further limited by regulatory domain constraints and AP capabilities.</p> <p>Range: 1 - 127</p>
eirp-min	<p>Minimum EIRP.</p> <p>Range: 1 - 127</p>
eirp-offset	<p>User offset of EIRP on top of algorithm choice.</p> <p>Range: Integer in [-6,6]</p> <p>Default: 0 dB</p>

Parameter	Description
<pre>frame-bursting-mode</pre>	<p>In some dense deployments, it is possible for APs to hear other APs on the same channel. This creates co-channel interference where the traffic of an active client could affect the air traffic of neighboring APs within the same channel. Starting from ArubaOS 8.11.0.0, users are allowed to control frame bursting even if there's only one active client associated to the AP.</p> <ul style="list-style-type: none"> ■ Dynamic: Frame bursting will be enabled only when one active client is connected to the AP, and frame bursting will be disabled when there is more than one active client. ■ OFF: Frame bursting mode is always disabled. ■ ON: Frame bursting mode is always enabled.
<pre>he-duration-based-rts-6ghz <he-duration-based-rts-6ghz></pre>	<p>Indicates HE duration-based RTS value. When the TXOP is greater than the configured HE duration based RTS value, RTS/CTS exchange should be used. Range: 0-1023(units: 32ms).</p> <p>Default: 1023 1023: HE duration-based RTS will be disabled.</p>
<pre>he-guard-interval-6ghz {1600ns 3200ns 800ns}</pre>	<p>Enables or disables supported HE guard intervals.</p> <p>Default: All enabled</p>

Parameter	Description
he-mu-mimo-6ghz	Enables or disables HE MU-MIMO. (802.11ax APs only). Default: enabled
he-mu-ofdma-6ghz	Enables or disables HE MU-OFDMA. (802.11ax APs only). Default: enabled
he-supported-mcs-map-6ghz <he-supported-mcs-map-6ghz>	Comma list of max supported MCS for spatial streams 1 through 8. Valid values for max mcs are 7, 9, 11 and '-' ('-' means spatial stream is not supported, and it's not supported at first spatial stream). Max mcs of a spatial stream cannot be higher than the previous stream's. If a MCS is not valid for a particular combination of bandwidth and number of spatial streams, it will not be used for Tx and Rx. Default: 11,11,11,11,11,11,11,11
he-txbf-6ghz	Enables or disables HE TXBF. Default: enabled
he-ul-mu-mimo-6ghz	Enables or disables HE UL MU-MIMO. Default: disabled
ht-radio-profile <profile-name>	Configures high-throughput radio profile.
individual-twt-6ghz	Enables or disables Individual TWT support. Default: enabled

Parameter	Description
max-channel-bandwidth	Maximum channel bandwidth in MHz. Valid values are 20MHz, 40MHz, 80MHz and 160MHz. 80MHz and above is not allowed for dot11g-radio-profile.
max-mpdu-size-6ghz	Maximum size of an MPDU. Permitted values: 3895, 7991, 11454. Default: 11454
max-rx-a-mpdu-size-6ghz	Configures maximum size of a received aggregate MPDU. Allowed values are 8191, 16383, 32767, and 65535.
max-tx-a-mpdu-size-6ghz	Configures maximum size of a transmitted aggregate MPDU. Range: 1576-65535
max-vht-mpdu-size-6ghz	Configures maximum size of a VHT MPDU. Allowed values are 3895, 7991, and 11454. Default: 11454
maximum-distance	Configures maximum wireless-link distance [meters]. Used to derive slot-time and ACK and CTS timeouts.

Parameter	Description
	<p>0 means use defaults: timeouts are unmodified except for outdoor mesh-radios which use 16km. Upper limits: legacy/11N AP 20MHz: 52km; 11N AP 40MHz: 24km; 11AC AP: 48km. Values above maximum supported cause the maximum to be used, below 600m defaults are used. Outdoor mesh points start up with the maximum supported until configured.</p>
<pre>mgmt-frame-throttle-interval <mgmt-frame-throttle-interval></pre>	<p>Averaging interval for rate limiting mgmt frames from this radio in secs. 0 disables rate limiting.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p>
<pre>mgmt-frame-throttle-limit <mgmt-frame-throttle-limit></pre>	<p>Maximum number of mgmt frames that can come in from this radio in each throttle interval.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p>
<pre>min-mpdu-start-spacing-6ghz { .25 .5 0 1 16 2 4 8 }</pre>	<p>Minimum time between the start of adjacent subframes within an aggregate MPDU. Due to hardware differences, on some platforms this value will be silently restricted to 8us even if a lower value is configured.</p>
<pre>mode</pre>	<p>One of the operating modes for the AP.</p>

Parameter	Description
	Default: ap-mode
ap-mode	Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.
am-mode	Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.
spectrum-mode	Device operates as an spectrum monitor, and can send spectrum analysis data to a desktop or laptop client. For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS 8.x User Guide.
no	Negates any configured parameter.
radio-enable	Enables or disables radio configuration. Default: enabled
rts-mode	<p>RTS mode allows users to control RTS frame transmission to the clients.</p> <ul style="list-style-type: none"> ■ always-enable: RTS is used for every PPDU/ A-MPDU transmission. ■ always-disable: RTS is not used for any transmission. ■ default: The

Parameter	Description
	<p>default RTS mode configured in the wireless driver of the AP is used. For 300 Series, 310 Series, 360 Series, 370 Series, AP-387, 530 Series, AP-555, 580 Series, 630 Series, and 635 Series access points, RTS is used for every alternate retried PPDU transmission. For 500H Series, 500 Series, 510 Series, 560 Series, 570 Series, 610 Series access points, RTS is used for all AMPDU transmissions.</p> <p>default</p>
spectrum-load-balancing	<p>The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP.</p> <p>Default: disabled</p>

Parameter	Description
<p>spectrum-monitoring</p>	<p>This parameter turns APs in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p> <p>For further details on using hybrid APs and spectrum monitors to examine the radio frequency (RF) environment in which the Wi-Fi network is operating, refer to the Spectrum Analysis chapter of the ArubaOS User Guide.</p> <p>For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS 8.x User Guide.</p> <p>default</p>
<p>spectrum-profile <profile></p>	<p>Specify the rf spectrum profile used by hybrid APs and spectrum monitors. This profile sets the spectrum band and device ageout times used by a spectrum monitor or hybrid AP radio. For details, see rf spectrum-profile on page 1254.</p>
<p>tx-power <tx-power></p>	<p>Sets the initial transmit power (dBm) on which the AP operates, unless a better choice is available through calibration.</p> <p>This parameter can be set from -51 to 51 in 0.1 dBm increments, or set to the regulatory maximum value of 127 dBm.</p>

Parameter	Description
	<p>Transmission power may be further limited by regulatory domain constraints and AP capabilities.</p> <p>NOTE: This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface.</p> <p>Range: -51 dBm to 51 dBm</p> <p>Default: 14 dBm</p>
<code>tx-rates-6ghz {12 18 24 36 48 54 6 9}</code>	<p>Sets the transmit rates for 6 GHz radio. The available values are 6, 9, 12, 18, 24, 36, 48, 54.</p>

Example

The following command enables the Agile Multiband Operation (MBO) for a 6 GHz radio profile "rf-6-635".

```
(host)[mynode](config)#rf dot11-6gHz-radio-profile rf-6-635
(host)[mynode] (6GHz radio profile "rf-6-635") #6ghz-dot11k-enable
(host)[mynode] (6GHz radio profile "rf-6-635") #6ghz-mbo-enable
```

Command History

Release	Modification
ArubaOS 8.11.0.0	The frame-bursting-mode and rts-mode parameters were introduced.

Description

This command configures AP radio settings for the 5 GHz frequency band, including the Adaptive Radio Management (ARM) profile for standalone controllers and the high-throughput (802.11n) radio profile. Channels must be valid for the country configured in the AP regulatory domain profile (see [ap regulatory-domain-profile on page 341](#)). To view the supported channels, use the `show ap allowed-channels` command.

APs initially start up with default **ack-timeout**, **cts-timeout** and **slot-time** values. When you modify the `maximum-distance` parameter in an `rf dot11a` radio profile or `rf dot11g` radio profile, new **ack-timeout**, **cts-timeout** and **slot-time** values may be derived, but those values are never less than the default values for an indoor AP.

Mesh radios on outdoor APs have additional constraints, as mesh links may need to span long distances. For mesh radios on outdoor APs, the effect of the default `maximum-distance` parameter on the **ack-timeout**, **cts-timeout** and **slot-time** values depends on whether the APs are configured as mesh portals or mesh points. This is because mesh portals use a default **maximum-distance** value of 16,050 meters, and mesh points use, by default, the maximum possible **maximum-distance** value.

The **maximum-distance** value should be set correctly to span the largest link distance in the mesh network so that when a mesh point gets the configuration from the network it will apply the correct **ack-timeout**, **cts-timeout** and **slot-time** values. The values derived from the **maximum-distance** setting depend on the band and whether 20MHz/40MHz mode of operation is in use.

The following table indicates values for a range of distances:

Timeouts[usec]	--- 5GHz radio ---			--- 2.4GHz radio ---		
Distance[m]	Ack	CTS	Slot	Ack	CTS	Slot
0 (outdoor:16050m)	128	128	63	128	128	63
0 (indoor:600a,6450g)	25	25	9	64	48	9
200 (==default)	25	25	9	64	48	9
500	25	25	9	64	48	9
600	25	25	9	64	48	9
1050	28	28	13	64	48	31
5100	55	55	26	64	55	31
10050	88	88	43	88	88	43
15000	121	121	59	121	121	59
16050	128	128	63	128	128	63
58200(5G limit 20M)	409	409	203	-	-	-
52650(2.4G limit 20M)	-	-	-	372	372	185
27450(5G limit 40M)	204	204	101	-	-	-
24750(2.4G limit 40M)	-	-	-	186	186	92

Parameter	Description
<profile>	Name of this instance of the profile. The name must be 1-63 characters. default
am-scan-profile <name>	Configure an Air Monitor (AM) scanning profile. default
arm-profile	Configures Adaptive Radio Management (ARM) feature. See rf arm-profile on page 1151 . default
am-tx-mute	Mute the radio transmission when in AM mode. Disabled
assoc-boost	The assoc-boost parameter increases the client association success rate, especially in a noisy environment. When this parameter is enabled: <ul style="list-style-type: none"> ▪ The management frame retransmission retry limit in the radio firmware for both authentication and association response is increased, thereby increasing the management frame retransmission rate. ▪ If the management frame retransmission retry limit is reached, after a short time delay another round of management frames are scheduled. ▪ If a client starts an association (by sending a probe or authentication request), AP scanning is rejected for 5 seconds, thereby not missing the client association request. disabled
beacon-period	Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients. 60 (minimum) 100 milli-seconds
beacon-regulate	Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air. disabled

Parameter	Description
<pre>cap-reg-eirp <cap-reg-eirp></pre>	<p>Work around a known issue on Cisco 7921G telephones by specifying a cap for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.</p> <p>1–31 dBm</p>
<pre>cell-size-reduction <cell-size-reduction></pre>	<p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. This value should only be changed if the network is experiencing performance issues. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p> <p>Values from 1 dB - 55 dB reduce the power level that the radio can hear by that amount. If you configure this feature to use a non-default value, you must also reduce the radio's transmission (Tx) power to match its new received (Rx) power level. Failure to match a device's Tx power level to its Rx power level can result in a configuration that allows the radio to send messages to a device that it cannot hear.</p> <p>1-55dB</p> <p>0 dB</p>
<pre>channel</pre>	<p>Channel number for the AP 802.11a/802.11n/802.11ac physical layer. This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface.</p> <p>The available channels depend on the regulatory domain (country). Channel number configuration options for 20 MHz, 40 MHz, and 80 Mhz modes:</p> <ul style="list-style-type: none"> ▪ num: Entering a channel number disables 40 MHz mode and activates 20 MHz mode for the entered channel. ▪ num+: Entering a channel number with a plus (+) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by increasing the primary channel number by 4. Example: 157+ represents 157 as the primary channel and 161 as the secondary channel. ▪ num-: Entering a channel number with a minus (-) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by decreasing the primary

Parameter	Description
	<p>channel number by 4. Example: 157- represents 157 as the primary channel and 153 as the secondary channel.</p> <p>NOTE: 20 MHz clients are allowed to associate when a primary and secondary channel are configured; however, the client will only use the primary channel.</p> <p>Depends on regulatory domain</p>
channel-reuse	<p>When you enable the channel reuse feature, it can operate in either of the following three modes; static, dynamic or disable. (This feature is disabled by default.)</p> <ul style="list-style-type: none"> ▪ Static mode: This mode of operation is a coverage-based adaptation of the Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa. ▪ Dynamic mode: In this mode, the Clear Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client. ▪ Disable mode: This mode does not support the tuning of the CCA Detect Threshold. <p>enabled, disabled enabled</p>
channel-reuse-threshold	<p>RX Sensitivity Tuning Based Channel Reuse Threshold, in -dBm.</p> <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (in -dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength.</p> <p>If the value is set to zero, the feature will automatically determine an appropriate threshold.</p> <p>Depends on regulatory domain</p>
clone	<p>Name of an existing radio profile from which parameter values are copied.</p>

Parameter	Description
csa	<p>Channel Switch Announcement (CSA), as defined by IEEE 802.11h, allows an AP to announce that it is switching to a new channel before it begins transmitting on that channel. Clients must support CSA in order to track the channel change without experiencing disruption.</p> <p>disabled</p>
csa-count	<p>Number of CSA announcements that are sent before the AP begins transmitting on the new channel.</p> <p>1-16</p> <p>4</p>
deploy-hour <0-23>	<p>Specify a number from 0-23 to select the hour during which AirMatch updates are sent to the APs (in 24-hour format). If the managed device to which the AP is associated is in a different time zone than Mobility Conductor, the AirMatch solution will be deployed according to the time zone of the managed device.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller. If this parameter is set in both the AirMatch profile and the 802.11a radio profile, the setting in the 802.11a radio profile will take precedence.</p> <p>0-23</p> <p>5</p>
disable-arm-wids-functions	<p>Disables Adaptive Radio Management (ARM) and Wireless IDS functions. These can be disabled if a small increase in packet processing performance is desired. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled irrespective of this option.</p> <p>CAUTION: Use carefully, since this effectively disables ARM and WIDS.</p> <p>disabled</p>
dot11h	<p>Enable advertisement of 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities.</p> <p>disabled</p>
eirp-max <eirp-max>	<p>Maximum effective isotropic radiated power (EIRP) from 3 to 33 dBm. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p>

Parameter	Description
	1-127 18
<code>eirp-min <eirp-min></code>	<p>The minimum transmission power level (in dBm) to be assigned to the AP radio(s).</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> 1-127 12
<code>eirp-offset</code>	<p>Manually adjust EIRP levels selected by the AirMatch algorithm by specifying a value from -6 to 6 dBm.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> -6 to 6 dBm 0 dBm
<code>energy-detect-threshold</code>	<p>Modify the Energy Detect Threshold (EDT) used by the radio in making transmit decisions. The EDT is a negative value, and the value specified for this parameter (1-12) is the offset from the base value of -59 dBm. For example a value of 1 = -60 dBm, and a value of 10: = -69 dBm. Specify a value of 0 to use the default EDT for this radio. (This value may vary by AP model)</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> 0, 1-12 0 (disabled) Starting from ArubaOS 8.7.1.1, the range of <code>energy-detect-threshold</code> parameter has been modified from 0-12 to 12 to -29 dB.
<code>frame-bursting-mode</code>	<p>In some dense deployments, it is possible for APs to hear other APs on the same channel. This creates co-channel interference where the traffic of an active client could affect the air traffic of neighboring APs within the same channel. Starting from ArubaOS 8.11.0.0, users are allowed to control frame bursting even if there's only one active client associated to the AP.</p> <ul style="list-style-type: none"> Dynamic: Frame bursting will be enabled only when

Parameter	Description
	<p>one active client is connected to the AP, and frame bursting will be disabled when there is more than one active client.</p> <ul style="list-style-type: none"> ■ OFF: Frame bursting mode is always disabled. ■ ON: Frame bursting mode is always enabled.
high-efficiency-enable <radio>	<p>Enables high-efficiency (802.11ax) features on a radio by using the 5 GHz frequency band.</p> <p>enabled</p>
high-throughput-enable	<p>Enables high-throughput (802.11n) features on a radio using the 5 GHz frequency band.</p> <p>enabled</p>
ht-radio-profile	<p>Name of high-throughput radio profile to use for configuring high-throughput support on the 5 GHz frequency band. See rf ht-radio-profile on page 1249.</p> <p>default-a</p>
interference-immunity	<p>Set a value for 802.11 interference immunity. This parameter sets the interference immunity on the 5 GHz band. When performance drops due to interference from non- 802.11 interferers (such as DECT or Bluetooth devices), the level can be increased for improved performance. There are 17 levels (0-16) and Table 8 lists the settings applied for each level.</p> <p>NOTE: It is recommended not to adjust interference immunity without guidance from Aruba support. Increasing the immunity level in a healthy network may result in severe loss of performance. This should be set to a higher than default level only when there is significant degradation due to non-Wi-Fi interference.</p> <p>0-16 2</p>
max-channel-bandwidth	<p>Sets the maximum channel bandwidth for APs associated to Mobility Conductor managed devices.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>20MHz, 40MHz, 80MHz or 160MHz 80MHz</p>
minimum-channel-bandwidth	<p>Sets the minimum channel bandwidth for APs associated to Mobility Conductor managed devices.</p>

Parameter	Description
	<p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>20MHz, 40MHz, 80MHz 20MHz</p>
min-mpdu-start-spacing-6Ghz	Sets the minimum time between the start of adjacent subframes within an aggregate MPDU. Due to hardware differences, on some platforms this value will be silently restricted to 8us even if a lower value is configured.
maximum-distance	<p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.</p> <p>The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 5 GHz frequency band radio:</p> <ul style="list-style-type: none"> ▪ 20MHz mode: 58km ▪ 40MHz mode: 27km <p>Note that if you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600m will use default settings.</p> <p>0-57km (40MHz mode), 0-27km (20MHz mode) 0 meters</p>
mgmt-frame-throttle-interval	<p>Averaging interval for rate limiting management frames in seconds. Zero disables rate limiting.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p> <p>0-60 1 second interval</p>
mgmt-frame-throttle-limit	<p>Maximum number of management frames allowed in each throttle interval.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p> <p>0-999999 20 frames per interval</p>
mode	<p>One of the operating modes for the AP.</p> <p>ap-mode</p>

Parameter	Description
ap-mode	Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.
am-mode	Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.
spectrum-mode	Device operates as a spectrum monitor, and can send spectrum analysis data to a desktop or laptop client.
no	Negates any configured parameter.
radar-test-mode	For internal use only.
radio-enable	Enables or disables radio configuration. enabled
rts-mode	RTS mode allows users to control RTS frame transmission to the clients. <ul style="list-style-type: none"> ■ always-enable: RTS is used for every PPDU/ A-MPDU transmission. ■ always-disable: RTS is not used for any transmission. ■ default: The default RTS mode configured in the wireless driver of the AP is used. For 300 Series, 310 Series, 360 Series, 370 Series, AP-387, 530 Series, AP-555, 580 Series, 630 Series, and 635 Series access points, RTS is used for every alternate retried PPDU transmission. For 500H Series, 500 Series, 510 Series, 560 Series, 570 Series, 610 Series access points, RTS is used for all AMPDU transmissions. default
slb-mode channel radio	SLB Mode allows control over how to balance clients. Select one of the following options <ul style="list-style-type: none"> ■ channel: Channel-based load-balancing balances clients across channels. This is the default load-balancing mode ■ radio: Radio-based load-balancing balances clients across APs channel
slb-update-interval <secs>	Specify how often spectrum load balancing calculations are made (in seconds). 1-2147483647 seconds 30 seconds
smart-antenna	Enable or disable the smart antenna feature on AP-335 access points. enabled, disabled

Parameter	Description
	enabled
spectrum-load-bal -domain	<p>Define a spectrum load balancing domain to manually create RF neighborhoods.</p> <p>Use this option to create RF neighborhood information for networks that have disabled Adaptive Radio Management (ARM) scanning and channel assignment.</p> <ul style="list-style-type: none"> ▪ If spectrum load balancing is enabled in a 802.11a radio profile but the spectrum load balancing domain is not defined, ArubaOS uses ARM to calculate RF neighborhoods. ▪ If spectrum load balancing is enabled in a 802.11a radio profile and a spectrum load balancing domain is also defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by ARM.
spectrum-load- balancing	<p>The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP.</p> <p>disabled</p>
spectrum-monitoring	<p>Issue this command to turn APs in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p> <p>For further details on using hybrid APs and spectrum monitors to examine the radio frequency (RF) environment in which the Wi-Fi network is operating, refer to the Spectrum Analysis chapter of the ArubaOS User Guide.</p> <p>For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS 8.x User Guide.</p> <p>default</p>
spectrum-profile <profile>	<p>Specify the rf spectrum profile used by hybrid APs and spectrum monitors. This profile sets the spectrum band and device ageout times used by a spectrum monitor or hybrid AP radio. For details, see rf spectrum-profile on page 1254.</p> <p>default</p>

Parameter	Description
<code>spur-immunity <spur-immunity></code>	<p>Spur Immunity for 5 GHz radio. This parameter fine-tunes the Cyclic Power Threshold (CPT) of a 5 GHz radio. The value specified here is the offset from the base value of 2 dB (for example, setting the CPT value to 1 corresponds to 2 + 1 = 3 dB. Similarly, setting the CPT value to 10 corresponds to 2+10 = 12 dB).</p> <p>Use this parameter when high channel utilization is observed in the 5 GHz radio of 130 Series access points in a noise-free environment causing client association or throughput issues.</p> <p>Adjust the CPT value to eliminate the spur impacts. Range definition is as follows:</p> <ul style="list-style-type: none"> ▪ 0: default CPT ▪ 1-19: CPT growth from default (3 dB to 21 dB) ▪ 20: Setting this parameter to 20 sets the cell-size-reduction value to 1. Cell-size-reduction is the receive coverage area of the AP. <p>NOTE: Configure this parameter under the supervision of Aruba Technical Support.</p> <p>NOTE: Setting the spur immunity to a higher value may decrease the AP RF coverage.</p> <p>NOTE: This parameter is applicable for 130 Series access points only. The controller ignores this parameter if configured for non-130 Series access points.</p> <p>0-20 CPT 0 CPT</p>
<code>transmit</code>	<p>Enable or disable transmission of frames on the radio.</p> <p>NOTE: This parameter should only be used for radio test purposes.</p> <p>enabled, disabled disabled</p>
<code>tx-power</code>	<p>Sets the initial transmit power (dBm) on which the AP operates, unless a better choice is available through calibration. This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface. This parameter can be set from -51 to 51 in 0.1 dBm increments, or set to the regulatory maximum value of 127 dBm. Transmission power may be further limited by regulatory domain constraints and AP capabilities.</p>

Parameter	Description
	<p>NOTE: Use this parameter to set transmit power levels for APs associated to a stand-alone controller not using ARM.</p> <p>-51 dBm to 51 dBm 14 dBm</p>
very-high-throughput-enable	<p>Enable or disable support for Very High Throughput (802.11ac) on the radio.</p> <p>Enabled</p>
zero-wait-dfs	<p>Enable or disable support for zero-wait DFS channel feature. This feature provides seamless change of channels and avoids the period of no transmission. Hence, stations do not lose their connectivity when an AP moves to a DFS channel.</p> <p>Default: Disabled</p> <p>NOTE: All 510 Series, 518 Series, 530 Series, 550 Series, 570 Series, 580 Series, and 650 Series access points having 4x4 5 GHz radios support the zero-wait DFS feature.</p>

Examples

The following command configures APs to operate in AM mode for the selected dot11a-radio-profile named "sample-a:"

```
(host) [node] (config) #rf dot11a-radio-profile sample-a mode am-mode
```

The following command configures APs to operate in high-throughput (802.11n) mode on the 5 GHz frequency band for the selected dot11a-radio profile named "sample-a-" and assigns a high-throughput radio profile named "default-a:"

```
(host) [node] (config) #rf dot11a-radio-profile sample-a
high-throughput-enable
ht-radio-profile default-a
```

The following command configures a primary channel number of 157 and a secondary channel number of 161 for 40 MHz mode of operation with a dot11a-radio profile named "sample-a:"

```
(host) [node] (config) #rf dot11a-radio-profile sample-a channel <157+>
```

The following table indicates the interference immunity implementation for each level.

Table 8: Interference Immunity Levels

Immunity Level	Adaptive Noise Immunity (ANI)	Preemption Mode	Low Noise Amplifier (LNA)	Interference Sensitivity Reduction	Force Noise Floor (for 2.4 GHz radio only)
0	Disabled	Disabled	Enabled	None	None
1	Enabled	Disabled	Enabled	None	None
2	Enabled	Enabled	Enabled	None	None
3	Enabled	Enabled	Enabled	None	None
4	Enabled	Enabled	Enabled	4 dB	None
5	Enabled	Enabled	Enabled	8 dB	None
6	Enabled	Enabled	Enabled	12 dB	None
7	Enabled	Enabled	Enabled	16 dB	None
8	Enabled	Enabled	Enabled	None	-85 dB
9	Enabled	Enabled	Enabled	None	-80 dB
10	Enabled	Enabled	Enabled	None	-75 dB
11	Enabled	Enabled	Enabled	8 dB	-85 dB
12	Enabled	Enabled	Enabled	8 dB	-80 dB
13	Enabled	Enabled	Enabled	None	None
14	Enabled	Enabled	Enabled	None	None
15	Enabled	Enabled	Enabled	8 dB	None
16	Enabled	Enabled	Enabled	16 dB	None

- **Adaptive Noise Immunity:** Adjust noise and spur immunity levels based on PHY errors.
- **Preemption mode:** The radio stops current reception and restarts the receiver when a new signal which is above the threshold of the current signal is found. This allows the radio to switch signals when it locks onto interference or weaker 802.11 signal, when a valid 802.11 signal with a higher signal strength is detected.
- **Low Noise Amplifier:** Enables radio saturation at lower signal levels resulting in better performance in the presence of interference. Disabling LNA avoids radio saturation at lower signal levels. However, it may reduce range and throughput.

Immunity Level	Adaptive Noise Immunity (ANI)	Preemption Mode	Low Noise Amplifier (LNA)	Interference Sensitivity Reduction	Force Noise Floor (for 2.4 GHz radio only)
<ul style="list-style-type: none"> ▪ Interference Sensitivity Reduction: Reduces the sensitivity to both Wi-Fi and non Wi-Fi interference signals. This makes the radio deaf to signals in which the SNR is below the threshold. ▪ Force Noise Floor (for 2.4 GHz radio only): Forces the radio to use the configured value as the absolute noise floor value. This makes the radio ignore signals of weaker amplitude. 					

Command History

Release	Modification
ArubaOS 8.11.0.0	The frame-bursting-mode and rts-mode parameters were introduced.
ArubaOS 8.8.0.0	The <code>zero-wait-dfs</code> parameter was introduced.
ArubaOS 8.7.1.1	The range of <code>energy-detect-threshold</code> parameter has been modified from 0-12 to 12 to -29 dB.
ArubaOS 8.4.0.0	The <code>high-efficiency-enable <radio></code> parameter was added.
ArubaOS 8.2.0.0	Modified the range of the <code>eirp-max</code> and <code>eirp-min</code> parameters.
ArubaOS 8.1.0.0	The following parameters were added: <ul style="list-style-type: none"> ▪ <code>deploy-hour</code>, <code>eirp-offset</code> ▪ <code>energy-detect-threshold</code> ▪ <code>minimum-channel-bandwidth</code>
ArubaOS 8.0.0.0	Command introduced.

Description

This command configures AP radio settings for the 5 GHz frequency band, including the Adaptive Radio Management (ARM) profile for standalone controllers and the high-throughput (802.11n) radio profile. Channels must be valid for the country configured in the AP regulatory domain profile (see [ap regulatory-domain-profile on page 341](#)). To view the supported channels, use the `show ap allowed-channels` command.

APs initially start up with default **ack-timeout**, **cts-timeout** and **slot-time** values. When you modify the `maximum-distance` parameter in an `rf dot11a` radio profile or `rf dot11g` radio profile, new **ack-timeout**, **cts-timeout** and **slot-time** values may be derived, but those values are never less than the default values for an indoor AP.

Mesh radios on outdoor APs have additional constraints, as mesh links may need to span long distances. For mesh radios on outdoor APs, the effect of the default `maximum-distance` parameter on the **ack-timeout**, **cts-timeout** and **slot-time** values depends on whether the APs are configured as mesh portals or mesh points. This is because mesh portals use a default **maximum-distance** value of 16,050 meters, and mesh points use, by default, the maximum possible **maximum-distance** value.

The **maximum-distance** value should be set correctly to span the largest link distance in the mesh network so that when a mesh point gets the configuration from the network it will apply the correct **ack-timeout**, **cts-timeout** and **slot-time** values. The values derived from the **maximum-distance** setting depend on the band and whether 20MHz/40MHz mode of operation is in use.

The following table indicates values for a range of distances:

Timeouts[usec]	--- 5GHz radio ---			--- 2.4GHz radio ---		
Distance[m]	Ack	CTS	Slot	Ack	CTS	Slot
0 (outdoor:16050m)	128	128	63	128	128	63
0 (indoor:600a,6450g)	25	25	9	64	48	9
200 (==default)	25	25	9	64	48	9
500	25	25	9	64	48	9
600	25	25	9	64	48	9
1050	28	28	13	64	48	31
5100	55	55	26	64	55	31
10050	88	88	43	88	88	43
15000	121	121	59	121	121	59
16050	128	128	63	128	128	63
58200(5G limit 20M)	409	409	203	-	-	-
52650(2.4G limit 20M)	-	-	-	372	372	185
27450(5G limit 40M)	204	204	101	-	-	-
24750(2.4G limit 40M)	-	-	-	186	186	92

Parameter	Description
<profile>	Name of this instance of the profile. The name must be 1-63 characters. default

Parameter	Description
am-scan-profile <name>	Configure an Air Monitor (AM) scanning profile. default
arm-profile	Configures Adaptive Radio Management (ARM) feature. See rf arm-profile on page 1151 . default
assoc-boost	<p>The assoc-boost parameter increases the client association success rate, especially in a noisy environment. When this parameter is enabled:</p> <ul style="list-style-type: none"> ▪ The management frame retransmission retry limit in the radio firmware for both authentication and association response is increased, thereby increasing the management frame retransmission rate. ▪ If the management frame retransmission retry limit is reached, after a short time delay another round of management frames are scheduled. ▪ If a client starts an association (by sending a probe or authentication request), AP scanning is rejected for 5 seconds, thereby not missing the client association request. <p>disabled</p>
beacon-period	<p>Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.</p> <p>60 (minimum) 100 milli-seconds</p>
beacon-regulate	<p>Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air.</p> <p>disabled</p>
cap-reg-eirp <cap-reg-eirp>	<p>Work around a known issue on Cisco 7921G telephones by specifying a cap for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.</p> <p>1–31 dBm</p>

Parameter	Description
<p>cell-size-reduction <cell-size-reduction></p>	<p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. This value should only be changed if the network is experiencing performance issues. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p> <p>Values from 1 dB - 55 dB reduce the power level that the radio can hear by that amount. If you configure this feature to use a non-default value, you must also reduce the radio's transmission (Tx) power to match its new received (Rx) power level. Failure to match a device's Tx power level to its Rx power level can result in a configuration that allows the radio to send messages to a device that it cannot hear.</p> <p>1-55dB 0 dB</p>
<p>channel</p>	<p>Channel number for the AP 802.11a/802.11n/802.11ac physical layer. This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface.</p> <p>The available channels depend on the regulatory domain (country). Channel number configuration options for 20 MHz, 40 MHz, and 80 Mhz modes:</p> <ul style="list-style-type: none"> ▪ num: Entering a channel number disables 40 MHz mode and activates 20 MHz mode for the entered channel. ▪ num+: Entering a channel number with a plus (+) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by increasing the primary channel number by 4. Example: 157+ represents 157 as the primary channel and 161 as the secondary channel. ▪ num-: Entering a channel number with a minus (-) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by decreasing the primary channel number by 4. Example: 157- represents 157 as the primary channel and 153 as the secondary channel. <p>NOTE: 20 MHz clients are allowed to associate when a primary and secondary channel are configured; however, the client will only use the primary channel.</p> <p>Depends on regulatory domain</p>

Parameter	Description
channel-reuse	<p>When you enable the channel reuse feature, it can operate in either of the following three modes; static, dynamic or disable. (This feature is disabled by default.)</p> <ul style="list-style-type: none"> ■ Static mode: This mode of operation is a coverage-based adaptation of the Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa. ■ Dynamic mode: In this mode, the Clear Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client. ■ Disable mode: This mode does not support the tuning of the CCA Detect Threshold. <p>enabled, disabled enabled</p>
channel-reuse-threshold	<p>RX Sensitivity Tuning Based Channel Reuse Threshold, in -dBm.</p> <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (in -dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength.</p> <p>If the value is set to zero, the feature will automatically determine an appropriate threshold.</p> <p>Depends on regulatory domain</p>
clone	<p>Name of an existing radio profile from which parameter values are copied.</p>
csa	<p>Channel Switch Announcement (CSA), as defined by IEEE 802.11h, allows an AP to announce that it is switching to a new channel before it begins transmitting on that channel. Clients must support CSA in order to track the channel change without experiencing disruption.</p> <p>disabled</p>
csa-count	<p>Number of CSA announcements that are sent before the AP begins transmitting on the new channel.</p>

Parameter	Description
	1-16 4
<code>deploy-hour <0-23></code>	<p>Specify a number from 0-23 to select the hour during which AirMatch updates are sent to the APs (in 24-hour format). If the managed device to which the AP is associated is in a different time zone than Mobility Conductor, the AirMatch solution will be deployed according to the time zone of the managed device.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller. If this parameter is set in both the AirMatch profile and the 802.11a radio profile, the setting in the 802.11a radio profile will take precedence.</p> 0-23 5
<code>disable-arm-wids-functions</code>	<p>Disables Adaptive Radio Management (ARM) and Wireless IDS functions. These can be disabled if a small increase in packet processing performance is desired. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled irrespective of this option.</p> <p>CAUTION: Use carefully, since this effectively disables ARM and WIDS.</p> disabled
<code>dot11h</code>	<p>Enable advertisement of 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities.</p> disabled
<code>eirp-max <eirp-max></code>	<p>Maximum effective isotropic radiated power (EIRP) from 3 to 33 dBm. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> 1-127 18
<code>eirp-min <eirp-min></code>	<p>The minimum transmission power level (in dBm) to be assigned to the AP radio(s).</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone</p>

Parameter	Description
	<p>controller.</p> <p>1-127</p> <p>12</p>
eirp-offset	<p>Manually adjust EIRP levels selected by the AirMatch algorithm by specifying a value from -6 to 6 dBm.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>-6 to 6 dBm</p> <p>0 dBm</p>
energy-detect-threshold	<p>Modify the Energy Detect Threshold (EDT) used by the radio in making transmit decisions. The EDT is a negative value, and the value specified for this parameter (1-12) is the offset from the base value of -59 dBm. For example a value of 1 = -60 dBm, and a value of 10: = -69 dBm. Specify a value of 0 to use the default EDT for this radio. (This value may vary by AP model)</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>0, 1-12</p> <p>0 (disabled)</p> <p>Starting from ArubaOS 8.7.1.1, the range of <code>energy-detect-threshold</code> parameter has been modified from 0-12 to 12 to -29 dB.</p>
frame-bursting-mode	<p>In some dense deployments, it is possible for APs to hear other APs on the same channel. This creates co-channel interference where the traffic of an active client could affect the air traffic of neighboring APs within the same channel. Starting from ArubaOS 8.11.0.0, users are allowed to control frame bursting even if there's only one active client associated to the AP.</p> <ul style="list-style-type: none"> ■ Dynamic: Frame bursting will be enabled only when one active client is connected to the AP, and frame bursting will be disabled when there is more than one active client. ■ OFF: Frame bursting mode is always disabled. ■ ON: Frame bursting mode is always enabled.
high-efficiency-enable <radio>	<p>Enables high-efficiency (802.11ax) features on a radio by using the 5 GHz frequency band.</p>

Parameter	Description
	enabled
high-throughput-enable	Enables high-throughput (802.11n) features on a radio using the 5 GHz frequency band. enabled
ht-radio-profile	Name of high-throughput radio profile to use for configuring high-throughput support on the 5 GHz frequency band. See rf ht-radio-profile on page 1249 . default-a
interference-immunity	Set a value for 802.11 interference immunity. This parameter sets the interference immunity on the secondary 5 GHz band. When performance drops due to interference from non- 802.11 interferers (such as DECT or Bluetooth devices), the level can be increased for improved performance. There are 17 levels (0-16) and Table 9 lists the settings applied for each level. NOTE: It is recommended not to adjust interference immunity without guidance from Aruba support. 0-16 2
max-channel-bandwidth	Sets the maximum channel bandwidth for APs associated to Mobility Conductor managed devices. NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller. 20MHz, 40MHz, 80MHz or 160MHz 80MHz
minimum-channel-bandwidth	Sets the minimum channel bandwidth for APs associated to Mobility Conductor managed devices. NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller. 20MHz, 40MHz, 80MHz 20MHz

Parameter	Description
maximum-distance	<p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km.</p> <p>The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 5 GHz frequency band radio:</p> <ul style="list-style-type: none"> ▪ 20MHz mode: 58km ▪ 40MHz mode: 27km <p>Note that if you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600m will use default settings.</p> <p>0-57km (40MHz mode), 0-27km (20MHz mode)</p> <p>0 meters</p>
mgmt-frame-throttle-interval	<p>Averaging interval for rate limiting management frames in seconds. Zero disables rate limiting.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p> <p>0-60</p> <p>1 second interval</p>
mgmt-frame-throttle-limit	<p>Maximum number of management frames allowed in each throttle interval.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p> <p>0-999999</p> <p>20 frames per interval</p>
mode	<p>One of the operating modes for the AP.</p> <p>ap-mode</p>
ap-mode	<p>Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.</p>
am-mode	<p>Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.</p>
spectrum-mode	<p>Device operates as a spectrum monitor, and can send spectrum analysis data to a desktop or laptop client.</p>
no	<p>Negates any configured parameter.</p>

Parameter	Description
radar-test-mode	For internal use only.
radio-enable	Enables or disables radio configuration. enabled
rts-mode	RTS mode allows users to control RTS frame transmission to the clients. <ul style="list-style-type: none"> ■ always-enable: RTS is used for every PPDU/ A-MPDU transmission. ■ always-disable: RTS is not used for any transmission. ■ default: The default RTS mode configured in the wireless driver of the AP is used. For 300 Series, 310 Series, 360 Series, 370 Series, AP-387, 530 Series, AP-555, 580 Series, 630 Series, and 635 Series access points, RTS is used for every alternate retried PPDU transmission. For 500H Series, 500 Series, 510 Series, 560 Series, 570 Series, 610 Series access points, RTS is used for all AMPDU transmissions. default
slb-mode channel radio	SLB Mode allows control over how to balance clients. Select one of the following options <ul style="list-style-type: none"> ■ channel: Channel-based load-balancing balances clients across channels. This is the default load-balancing mode ■ radio: Radio-based load-balancing balances clients across APs channel
slb-update-interval <secs>	Specify how often spectrum load balancing calculations are made (in seconds). 1-2147483647 seconds 30 seconds
smart-antenna	Enable or disable the smart antenna feature on AP-335 access points. enabled, disabled enabled
spectrum-load-bal -domain	Define a spectrum load balancing domain to manually create RF neighborhoods. Use this option to create RF neighborhood information for networks that have disabled Adaptive Radio Management (ARM) scanning and channel assignment. <ul style="list-style-type: none"> ■ If spectrum load balancing is enabled in a 802.11a radio profile but the spectrum load balancing domain is not defined, ArubaOS uses ARM to calculate RF neighborhoods.

Parameter	Description
	<ul style="list-style-type: none"> If spectrum load balancing is enabled in a 802.11a radio profile and a spectrum load balancing domain is also defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by ARM.
<pre>spectrum-load-balancing</pre>	<p>The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP.</p> <p>disabled</p>
<pre>spectrum-monitoring</pre>	<p>Issue this command to turn APs in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p> <p>For further details on using hybrid APs and spectrum monitors to examine the radio frequency (RF) environment in which the Wi-Fi network is operating, refer to the Spectrum Analysis chapter of the ArubaOS User Guide.</p> <p>For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS 8.x User Guide.</p> <p>default</p>
<pre>spectrum-profile <profile></pre>	<p>Specify the rf spectrum profile used by hybrid APs and spectrum monitors. This profile sets the spectrum band and device ageout times used by a spectrum monitor or hybrid AP radio. For details, see rf spectrum-profile on page 1254.</p> <p>default</p>
<pre>spur-immunity <spur-immunity></pre>	<p>Spur Immunity for 5 GHz radio. This parameter fine-tunes the Cyclic Power Threshold (CPT) of a 5 GHz radio. The value specified here is the offset from the base value of 2 dB (for example, setting the CPT value to 1 corresponds to 2 + 1 = 3 dB. Similarly, setting the CPT value to 10 corresponds to 2+10 = 12 dB).</p> <p>Use this parameter when high channel utilization is observed in the 5 GHz radio of 130 Series access points in a noise-free environment causing client association or throughput issues.</p> <p>Adjust the CPT value to eliminate the spur impacts. Range definition is as follows:</p>

Parameter	Description
	<ul style="list-style-type: none"> ▪ 0: default CPT ▪ 1-19: CPT growth from default (3 dB to 21 dB) ▪ 20: Setting this parameter to 20 sets the cell-size-reduction value to 1. Cell-size-reduction is the receive coverage area of the AP. <p>NOTE: Configure this parameter under the supervision of Aruba Technical Support.</p> <p>NOTE: Setting the spur immunity to a higher value may decrease the AP RF coverage.</p> <p>NOTE: This parameter is applicable for 130 Series access points only. The controller ignores this parameter if configured for non-130 Series access points.</p> <p>0-20 CPT 0 CPT</p>
transmit	<p>Enable or disable transmission of frames on the radio.</p> <p>NOTE: This parameter should only be used for radio test purposes.</p> <p>enabled, disabled disabled</p>
tx-power	<p>Sets the initial transmit power (dBm) on which the AP operates, unless a better choice is available through calibration. This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface. This parameter can be set from -51 to 51 in 0.1 dBm increments, or set to the regulatory maximum value of 127 dBm. Transmission power may be further limited by regulatory domain constraints and AP capabilities.</p> <p>NOTE: Use this parameter to set transmit power levels for APs associated to a stand-alone controller not using ARM.</p> <p>-51 dBm to 51 dBm 14 dBm</p>
very-high-throughput-enable	<p>Enable or disable support for Very High Throughput (802.11ac) on the radio.</p> <p>Enabled</p>

Parameter	Description
zero-wait-dfs	<p>Enable or disable support for zero-wait DFS channel feature. This feature provides seamless change of channels and avoids the period of no transmission. Hence, stations do not lose their connectivity when an AP moves to a DFS channel. Default: Disabled</p> <p>NOTE: All 500 Series, 500H Series, 510 Series, 530 Series, 550 Series, 560 Series, 570 Series, and 650 Series access points support the zero-wait DFS feature.</p>

Examples

The following command configures APs to operate in AM mode for the selected secondary dot11a-radio-profile named "sample-a:"

```
(host) [node] (config) #rf dot11a-secondary-radio-profile sample-a mode am-mode
```

The following command configures APs to operate in high-throughput (802.11n) mode on the 5 Ghz frequency band for the selected secondary dot11a-radio profile named "samplea-" and assigns a high-throughput radio profile named "default-a:"

```
(host) [node] (config) #rf dot11a-secondary-radio-profile
sample-a
high-throughput-enable
ht-radio-profile default-a
```

The following command configures a primary channel number of 157 and a secondary channel number of 161 for 40 MHz mode of operation with a secondary dot11a-radio profile named "sample-a:"

```
(host) [node] (config) #rf dot11a-secondary-radio-profile sample-a channel
<157+>
```

Table 9: *Interference Immunity Levels*

Immunity Level	Adaptive Noise Immunity (ANI)	Preemption Mode	Low Noise Amplifier (LNA)	Interference Sensitivity Reduction	Force Noise Floor (for 2.4 GHz radio only)
0	Disabled	Disabled	Enabled	None	None

1	Enabled	Disabled	Enabled	None	None
2	Enabled	Enabled	Enabled	None	None
3	Enabled	Enabled	Enabled	None	None
4	Enabled	Enabled	Enabled	4 dB	None
5	Enabled	Enabled	Enabled	8 dB	None
6	Enabled	Enabled	Enabled	12 dB	None
7	Enabled	Enabled	Enabled	16 dB	None
8	Enabled	Enabled	Enabled	None	-85 dB
9	Enabled	Enabled	Enabled	None	-80 dB
10	Enabled	Enabled	Enabled	None	-75 dB
11	Enabled	Enabled	Enabled	8 dB	-85 dB
12	Enabled	Enabled	Enabled	8 dB	-80 dB
13	Enabled	Enabled	Enabled	None	None
14	Enabled	Enabled	Enabled	None	None
15	Enabled	Enabled	Enabled	8 dB	None
16	Enabled	Enabled	Enabled	16 dB	None

- **Adaptive Noise Immunity:** Adjust noise and spur immunity levels based on PHY errors.
- **Preemption mode:** The radio stops current reception and restarts the receiver when a new signal which is above the threshold of the current signal is found. This allows the radio to switch signals when it locks onto interference or weaker 802.11 signal, when a valid 802.11 signal with a higher signal strength is detected.
- **Low Noise Amplifier:** Enables radio saturation at lower signal levels resulting in better performance in the presence of interference. Disabling LNA avoids radio saturation at lower signal levels. However, it may reduce range and throughput.
- **Interference Sensitivity Reduction:** Reduces the sensitivity to both Wi-Fi and non Wi-Fi interference signals. This makes the radio deaf to signals in which the SNR is below the threshold.
- **Force Noise Floor (for 2.4 GHz radio only):** Forces the radio to use the configured value as the absolute noise floor value. This makes the radio ignore signals of weaker amplitude.

Command History

Release	Modification
ArubaOS 8.11.0.0	The frame-bursting-mode and rts-mode parameters were introduced.
ArubaOS 8.8.0.0	The <code>zero-wait-dfs</code> parameter was introduced.
ArubaOS 8.7.1.1	The range of <code>energy-detect-threshold</code> parameter has been modified from 0-12 to 12 to -29 dB.
ArubaOS 8.4.0.0	The <code>high-efficiency-enable <radio></code> parameter was added.
ArubaOS 8.2.0.0	Modified the range of the <code>eirp-max</code> and <code>eirp-min</code> parameters.
ArubaOS 8.1.0.0	The following parameters were added: <ul style="list-style-type: none">▪ <code>deploy-hour</code>, <code>eirp-offset</code>▪ <code>energy-detect-threshold</code>▪ <code>minimum-channel-bandwidth</code>
ArubaOS 8.0.0.0	Command introduced.

rf dot11-60GHz-radio-profile

```
rf dot11-60GHz-radio-profile <profile>
  channel
  clone
  no
```

Description

This command configures AP radio settings for the 60 GHz frequency band on a 802.11 60 GHz radio profile. Channels must be valid for the country configured in the AP regulatory domain profile (see [ap regulatory-domain-profile on page 341](#)). To view the supported channels, use the `show ap allowed-channels` command.

Parameter	Description
channel	Indicates the radio channel. Range: 0-3 Default: 2 NOTE: Channel 1 is not recommended due to EIRP limitations.
clone	Copies data from a different 802.11 60 GHz radio profile.
no	Disables the 802.11 60 GHz radio profile configuration.

Examples

The following command configures APs for the selected 802.11 60 GHz radio profile named "default".

```
(host) [mynode] (config) # rf dot11-60GHz-radio-profile default
```

Description

This command configures AP radio settings for the 2.4 GHz frequency band, including the Adaptive Radio Management (ARM) profile and the high-throughput (802.11n) radio profile. Channels must be valid for the country configured in the AP regulatory domain profile (see [ap regulatory-domain-profile on page 341](#)). To view the supported channels, use the `show ap allowed-channels` command.

APs initially start up with default **ack-timeout**, **cts-timeout** and **slot-time** values. When you modify the `maximum-distance` parameter in an `rf dot11a` radio profile or `rf dot11g` radio profile, new **ack-timeout**, **cts-timeout** and **slot-time** values may be derived, but those values are never less than the default values for an indoor AP.

Mesh radios on outdoor APs have additional constraints, as mesh links may need to span long distances. For mesh radios on outdoor APs, the effect of the default `maximum-distance` parameter on the **ack-timeout**, **cts-timeout** and **slot-time** values depends on whether the APs are configured as mesh portals or mesh points. This is because mesh portals use a default **maximum-distance** value of 16,050 meters, and mesh points use, by default, the maximum possible **maximum-distance** value.

The **maximum-distance** value should be set correctly to span the largest link distance in the mesh network so that when a mesh point gets the configuration from the network it will apply the correct **ack-timeout**, **cts-timeout** and **slot-time** values. The values derived from the **maximum-distance** setting depend on the band and whether 20MHz/40MHz mode of operation is in use.

Parameter	Description
<code><profile></code>	Name of this instance of the profile. The name must be 1-63 characters. default
<code>airmatch-mode-aware</code>	If enabled, AirMatch turns off radios in high density deployment. Default: Disabled
<code>am-scan-profile <profile-name></code>	Configure an Air Monitor (AM) scanning profile.
<code>am-tx-mute</code>	Mute the radio transmission when in AM mode. Default: Disabled
<code>arm-profile</code>	Configures Adaptive Radio Management (ARM) feature. See rf arm-profile on page 1151 . default

Parameter	Description
assoc-boost	<p>The assoc-boost parameter increases the client association success rate, especially in a noisy environment. When this parameter is enabled:</p> <ul style="list-style-type: none"> ▪ The management frame retransmission retry limit in the radio firmware for both authentication and association response is increased, thereby increasing the management frame retransmission rate. ▪ If the management frame retransmission retry limit is reached, after a short time delay another round of management frames are scheduled. ▪ If a client starts an association (by sending a probe or authentication request), AP scanning is rejected for 5 seconds, thereby not missing the client association request. <p>disabled</p>
beacon-period	<p>Time, in milliseconds, between successive beacon transmissions. The beacon advertises the AP's presence, identity, and radio characteristics to wireless clients.</p> <p>60 (minimum) 100 milliseconds</p>
beacon-regulate	<p>Enabling this setting introduces randomness in the beacon generation so that multiple APs on the same channel do not send beacons at the same time, which causes collisions over the air.</p> <p>disabled</p>
cap-reg-eirp <cap-reg-eirp>	<p>Work around a known issue on Cisco 7921G telephones by specifying a cap for a radio's maximum equivalent isotropic radiated power (EIRP). When you enable this parameter, even if the regulatory approved maximum for a given channel is higher than this EIRP cap, the AP radio using this profile will advertise only this capped maximum EIRP in its radio beacons.</p> <p>1–31 dBm</p>

Parameter	Description
<code>cell-size-reduction <cell-size-reduction></code>	<p>The cell size reduction feature allows you manage dense deployments and to increase overall system performance and capacity by shrinking an AP's receive coverage area, thereby minimizing co-channel interference and optimizing channel reuse. This value should only be changed if the network is experiencing performance issues. The possible range of values for this feature is 0-55 dB. The default 0 dB reduction allows the radio to retain its current default Rx sensitivity value.</p> <p>Values from 1 dB - 55 dB reduce the power level that the radio can hear by that amount. If you configure this feature to use a non-default value, you must also reduce the radio's transmission (Tx) power to match its new received (Rx) power level. Failure to match a device's Tx power level to its Rx power level can result in a configuration that allows the radio to send messages to a device that it cannot hear.</p> <p>1-55dB 0 dB</p>
<code>channel</code>	<p>Channel number for the AP 802.11g/802.11n.802.11ac physical layer. The available channels depend on the regulatory domain (country). This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface.</p> <p>Channel number configuration options for 20 MHz, 40 MHz, and 80 Mhz modes:</p> <ul style="list-style-type: none"> ▪ num: Entering a channel number disables 40 MHz mode and activates 20 MHz mode for the entered channel. ▪ num+: Entering a channel number with a plus (+) sign selects a primary and secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by increasing the primary channel number by 4. Example: 157+ represents 157 as the primary channel and 161 as the secondary channel. ▪ num-: Entering a channel number with a minus (-) sign selects a primary and

Parameter	Description
	<p>secondary channel for 40 MHz and 80 Mhz modes. The number entered becomes the primary channel and the secondary channel is determined by decreasing the primary channel number by 4. Example: 157- represents 157 as the primary channel and 153 as the secondary channel.</p> <p>NOTE: 20 MHz clients are allowed to associate when a primary and secondary channel are configured; however, the client will only use the primary channel.</p> <p>Depends on regulatory domain</p>
clone	Name of an existing radio profile from which parameter values are copied.
csa	<p>Channel Switch Announcement (CSA), as defined by IEEE 802.11h, allows an AP to announce that it is switching to a new channel before it begins transmitting on that channel. Clients must support CSA in order to track the channel change without experiencing disruption.</p> <p>disabled</p>
csa-count	<p>Number of CSA announcements that are sent before the AP begins transmitting on the new channel.</p> <p>1-16</p> <p>4</p>
channel-reuse	<p>When you enable the channel reuse feature, it can operate in either of the following three modes; static, dynamic or disable. (This feature is disabled by default.)</p> <ul style="list-style-type: none"> ▪ Static mode: This mode of operation is a coverage-based adaptation of the Clear Channel Assessment (CCA) thresholds. In the static mode of operation, the CCA is adjusted according to the configured transmission power level on the AP, so as the AP transmit power decreases as the CCA threshold increases, and vice versa. ▪ Dynamic mode: In this mode, the Clear

Parameter	Description
	<p>Channel Assessment (CCA) thresholds are based on channel loads, and take into account the location of the associated clients. When you set the Channel Reuse This feature is automatically enabled when the wireless medium around the AP is busy greater than half the time. When this mode is enabled, the CCA threshold adjusts to accommodate transmissions between the AP its most distant associated client.</p> <ul style="list-style-type: none"> ▪ Disable mode: This mode does not support the tuning of the CCA Detect Threshold. <p>enabled, disabled enabled</p>
channel-reuse-threshold	<p>RX Sensitivity Tuning Based Channel Reuse Threshold, in -dBm.</p> <p>If the Rx Sensitivity Tuning Based Channel reuse feature is set to static mode, this parameter manually sets the AP's Rx sensitivity threshold (in -dBm). The AP will filter out and ignore weak signals that are below the channel threshold signal strength. If the value is set to zero, the feature will automatically determine an appropriate threshold.</p> <p>Depends on regulatory domain</p>
deploy-hour <0-23>	<p>Specify a number from 0-23 to select the hour during which AirMatch updates are sent to the APs (in 24-hour format). If the managed device to which the AP is associated is in a different time zone than Mobility Conductor, the AirMatch solution will be deployed according to the time zone of the managed device.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller. If this parameter is set in both the AirMatch profile and the 802.11g radio profile, the setting in the 802.11g radio profile will take precedence.</p> <p>0-23 5</p>

Parameter	Description
disable-arm-wids-functions	<p>Disables Adaptive Radio Management (ARM) and Wireless IDS functions. These can be disabled if a small increase in packet processing performance is desired. If a radio is configured to operate in Air Monitor mode, then these functions are always enabled irrespective of this option.</p> <p>CAUTION: Use carefully, since this effectively disables ARM and WIDS.</p> <p>disabled</p>
dot11b-protection	<p>Enable or disable protection for 802.11b clients. This parameter is enabled by default. Disabling this feature may improve performance if there are no 802.11b clients on the WLAN.</p> <p>WARNING: Disabling protection violates the 802.11 standard and may cause interoperability issues. If this feature is disabled on a WLAN with 802.11b clients, the 802.11b clients will not detect an 802.11g client talking and can potentially transmit at the same time, thus garbling both frames.</p> <p>enabled</p>
dot11h	<p>Enable advertisement of 802.11d (Country Information) and 802.11h (TPC or Transmit Power Control) capabilities</p> <p>disabled</p>
eirp-max	<p>Maximum effective isotropic radiated power (EIRP) from 3 to 33 dBm in 3 dBm increments. You may also specify a special value of 127 dBm for regulatory maximum to disable power adjustments for environments such as outdoor mesh links.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33 or 127 9</p>
eirp-min	<p>The minimum transmission power level (in dBm) to be assigned to the AP radio(s).</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p>

Parameter	Description
	3, 6, 9, 12, 15, 18, 21, 24, 27, 30, 33 or 127 6
eirp-offset	<p>Manually adjust EIRP levels selected by the AirMatch algorithm by specifying a value from -6 to 6 dBm.</p> <p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>-6 to 6 dBm 0 dBm</p>
energy-detect-threshold	<p>Modify the Energy Detect Threshold (EDT) used by the radio in making transmit decisions. The EDT is a negative value, and the value specified for this parameter (1-12) is the offset from the base value of -59 dBm. For example a value of 1 = -60 dBm, and a value of 10: = -69 dBm.</p> <p>Specify a value of 0 to use the default EDT for this radio. (This value may vary by AP model)</p> <p>0, 1-12 0 (disabled)</p>
frame-bursting-mode	<p>In some dense deployments, it is possible for APs to hear other APs on the same channel. This creates co-channel interference where the traffic of an active client could affect the air traffic of neighboring APs within the same channel. Starting from ArubaOS 8.11.0.0, users are allowed to control frame bursting even if there's only one active client associated to the AP.</p> <ul style="list-style-type: none"> ■ Dynamic: Frame bursting will be enabled only when one active client is connected to the AP, and frame bursting will be disabled when there is more than one active client. ■ OFF: Frame bursting mode is always disabled. ■ ON: Frame bursting mode is always enabled.
high-efficiency-enable <radio>	<p>Enables high-efficiency (802.11ax) features on a radio using the 2.4 GHz frequency band.</p> <p>enabled</p>

Parameter	Description
high-throughput-enable	Enables high-throughput (802.11n) features on a radio using the 2.4 GHz frequency band. enabled
ht-radio-profile	Name of high-throughput radio profile to use for configuring high-throughput support on the 5 GHz frequency band. See rf ht-radio-profile on page 1249 . default-a
interference-immunity	Set a value for 802.11 interference immunity. This parameter sets the interference immunity on the 2.4 GHz band. When performance drops due to interference from non- 802.11 interferers (such as DECT or Bluetooth devices), the level can be increased for improved performance. There are 17 levels (0-16) and Table 10 lists the settings applied for each level. NOTE: It is recommended not to adjust interference immunity without guidance from Aruba support. Increasing the immunity level in a healthy network may result in severe loss of performance. This should be set to a higher than default level only when there is significant degradation due to non-Wi-Fi interference. 0-16 2
iot-coex-enable	Enables WLAN co-existence feature with IoT and avoids simultaneous transmissions. enabled
max-channel-bandwidth	Sets the maximum channel bandwidth for APs associated to Mobility Conductor managed devices. NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller. 20MHz, 40MHz, 80MHz or 160MHz 80MHz
min-channel-bandwidth	Sets the minimum channel bandwidth for APs associated to Mobility Conductor managed devices.

Parameter	Description
	<p>NOTE: This parameter is only supported on Mobility Conductor, and is not available in on a standalone controller.</p> <p>20MHz, 40MHz, 80MHz 20MHz</p>
maximum-distance	<p>Maximum distance between a client and an AP or between a mesh point and a mesh portal, in meters. This value is used to derive ACK and CTS timeout times. A value of 0 specifies default settings for this parameter, where timeouts are only modified for outdoor mesh radios which use a distance of 16km. The upper limit for this parameter varies, depending on the 20/40 MHz mode for a 2.4GHz frequency band radio:</p> <ul style="list-style-type: none"> ▪ 20MHz mode: 54km ▪ 40MHz mode: 24km <p>Note that if you configure a value above the supported maximum, the maximum supported value will be used instead. Values below 600m will use default settings.</p> <p>0-24km (40MHz mode), 0-54km (20MHz mode) 0 meters</p>
mgmt-frame-throttle-interval	<p>Averaging interval for rate limiting management frames in seconds. Zero disables rate limiting.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p> <p>0-60 1 second interval</p>
mgmt-frame-throttle-limit	<p>Maximum number of management frames allowed in each throttle interval.</p> <p>NOTE: This parameter only applies to AUTH and ASSOC/RE-ASSOC management frames.</p> <p>0-999999 20 frames per interval</p>
mode	<p>One of the operating modes for the AP. ap-mode</p>

Parameter	Description
ap-mode	Device provides transparent, secure, high-speed data communications between wireless network devices and the wired LAN.
am-mode	Device behaves as an air monitor to collect statistics, monitor traffic, detect intrusions, enforce security policies, balance traffic load, self-heal coverage gaps, etc.
spectrum-mode	Device operates as a spectrum monitor, and can send spectrum analysis data to a desktop or laptop client. For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS 8.x User Guide.
no	Negates any configured parameter.
rts-mode	RTS mode allows users to control RTS frame transmission to the clients. <ul style="list-style-type: none"> ■ always-enable: RTS is used for every PPDU/ A-MPDU transmission. ■ always-disable: RTS is not used for any transmission. ■ default: The default RTS mode configured in the wireless driver of the AP is used. For 300 Series, 310 Series, 360 Series, 370 Series, AP-387, 530 Series, AP-555, 580 Series, 630 Series, and 635 Series access points, RTS is used for every alternate retried PPDU transmission. For 500H Series, 500 Series, 510 Series, 560 Series, 570 Series, 610 Series access points, RTS is used for all AMPDU transmissions. default
radio-enable	Enables or disables radio configuration. enabled
slb-mode channel radio	SLB Mode allows control over how to balance clients. Select one of the following options: <ul style="list-style-type: none"> ■ channel: Channel-based load-balancing balances clients across channels. This is the default load-balancing mode ■ radio: Radio-based load-balancing balances clients across APs channel

Parameter	Description
s1b-threshold	<p>If the spectrum load balancing feature is enabled, this parameter controls the percentage difference between number of clients on a channel that triggers load balancing. The default value is 20%, meaning that spectrum load balancing is activated when there are 20% more clients on one channel than on another channel used by the AP radio.</p> <p>1-100%</p> <p>20%</p>
s1b-update-interval <secs>	<p>Specify how often spectrum load balancing calculations are made (in seconds). The default value is 30 seconds.</p> <p>1-2147483647 seconds</p> <p>30 seconds</p>
smart-antenna	<p>Enable or disable the smart antenna feature on AP-335 access points.</p> <p>enabled, disabled</p> <p>enabled</p>
spectrum-load-bal-domain	<p>Define a spectrum load balancing domain to manually create RF neighborhoods. Use this option to create RF neighborhood information for networks that have disabled Adaptive Radio Management (ARM) scanning and channel assignment.</p> <ul style="list-style-type: none"> ■ If spectrum load balancing is enabled in a 802.11g radio profile but the spectrum load balancing domain is <i>not</i> defined, ArubaOS uses ARM to calculate RF neighborhoods. ■ If spectrum load balancing is enabled in a 802.11g radio profile and a spectrum load balancing domain <i>isalso</i> defined, AP radios belonging to the same spectrum load balancing domain will be considered part of the same RF neighborhood for load balancing, and will not recognize RF neighborhoods defined by ARM.

Parameter	Description
spectrum-load-balancing	<p>The Spectrum Load Balancing feature helps optimize network resources by balancing clients across channels, regardless of whether the AP or the controller is responding to the wireless clients' probe requests.</p> <p>If enabled, the controller compares whether or not an AP has more clients than its neighboring APs on other channels. If an AP's client load is at or over a predetermined threshold as compared to its immediate neighbors, or if a neighboring Aruba AP on another channel does not have any clients, load balancing will be enabled on that AP.</p> <p>disabled</p>
spectrum-monitoring	<p>Issue this command to turn APs in ap-mode into a hybrid AP. An AP in hybrid AP mode will continue to serve clients as an access point while it scans and analyzes spectrum analysis data for a single radio channel.</p> <p>For further details on using hybrid APs and spectrum monitors to examine the radio frequency (RF) environment in which the Wi-Fi network is operating, refer to the Spectrum Analysis chapter of the ArubaOS User Guide. For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS 8.x User Guide.</p> <p>default</p>
spectrum-profile <profile>	<p>Specify the rf spectrum profile used by hybrid APs and spectrum monitors. This profile sets the spectrum band and device ageout times used by a spectrum monitor or hybrid AP radio. For details, see rf spectrum-profile on page 1254.</p> <p>default</p>
transmit	<p>Enable or disable transmission of frames on the radio.</p> <p>NOTE: This parameter should only be used for radio test purposes.</p> <p>enabled, disabled</p> <p>disabled</p>
tx-power	<p>Sets the initial transmit power (dBm) on which the AP operates, unless a better choice is available through calibration.</p>

Parameter	Description
	<p>This parameter can be set from -51 to 51 in 0.1 dBm increments, or set to the regulatory maximum value of 127 dBm. Transmission power may be further limited by regulatory domain constraints and AP capabilities.</p> <p>NOTE: This parameter is only supported on a standalone controller, and is not available in the Mobility Conductor command-line interface.</p> <p>-51 dBm to 51 dBm 14 dBm</p>
very-high-throughput-rates-enable	<p>This feature enables Very High Throughput (VHT) rates on the 2.4 GHz band, providing 256-QAM modulation and encoding that allows for 600 Mbit/sec performance over 802.11n networks. Maximum data rates are increased on the 2.4 GHz band through the addition of VHT Modulation and Coding Scheme (MCS) values 8 and 9, which support the highly efficient modulation rates in 256-QAM. Starting with ArubaOS 6.4.2.0, VHT is supported on 220 Series access points on both 20 and 40 MHz channels.</p> <p>Using the controller's CLI or WebUI, VHT MCS values 0-9 are enabled, overriding the existing high-throughput (HT) MCS values 0-7, which have a lower maximum data rate. However, this feature should be disabled if individual rate selection is required.</p> <p>disabled</p>

The following table indicates values for a range of distances:

Timeouts[usec] Distance[m]	5GHz radio			2.4GHz radio		
	Ack	CTS	Slot	Ack	CTS	Slot
0 (outdoor:16050m)	128	128	63	128	128	63
0 (indoor:600a,6450g)	25	25	9	64	48	9
200 (==default)	25	25	9	64	48	9
500	25	25	9	64	48	9
600	25	25	9	64	48	9
1050	28	28	13	64	48	31
5100	55	55	26	64	55	31
10050	88	88	43	88	88	43
15000	121	121	59	121	121	59
16050	128	128	63	128	128	63
58200 (5G limit 20M)	409	409	203	-	-	-

```

52650 (2.4G limit 20M) - - - 372 372 185
27450 (5G limit 40M) 204 204 101 - - -
24750 (2.4G limit 40M) - - - 186 186 92

```

Examples

The following command configures APs to operate in AM mode for the selected dot11g-radio-profile named "sample-g".

```

(host)[mynode](config)#rf dot11g-radio-profile sample-g
mode am-mode

```

The following command configures APs to operate in high-throughput (802.11n) mode on the 2.4 GHz frequency band for the selected dot11g-radio profile named "sample-g" and assigns a high-throughput radio profile named "default-g".

```

(host)[mynode](config)#rf dot11g-radio-profile sample-g
high-throughput-enable
ht-radio-profile default-g

```

The following command configures a primary channel number of 1 and a secondary channel number of 5 for 40 MHz mode of operation with the dot11g-radio profile named "sample-g".

```

(host)[mynode](config)# rf dot11g-radio-profile sample-g channel <1+>

```

The following table indicates the interference immunity implementation for each level.

Table 10: *Interference Immunity Levels*

Immunity Level	Adaptive Noise Immunity (ANI)	Preemption Mode	Low Noise Amplifier (LNA)	Interference Sensitivity Reduction	Force Noise Floor (for 2.4 GHz radio only)
0	Disabled	Disabled	Enabled	None	None
1	Enabled	Disabled	Enabled	None	None
2	Enabled	Enabled	Enabled	None	None
3	Enabled	Enabled	Enabled	None	None

Immunity Level	Adaptive Noise Immunity (ANI)	Preemption Mode	Low Noise Amplifier (LNA)	Interference Sensitivity Reduction	Force Noise Floor (for 2.4 GHz radio only)
4	Enabled	Enabled	Enabled	4 dB	None
5	Enabled	Enabled	Enabled	8 dB	None
6	Enabled	Enabled	Enabled	12 dB	None
7	Enabled	Enabled	Enabled	16 dB	None
8	Enabled	Enabled	Enabled	None	-85 dB
9	Enabled	Enabled	Enabled	None	-80 dB
10	Enabled	Enabled	Enabled	None	-75 dB
11	Enabled	Enabled	Enabled	8 dB	-85 dB
12	Enabled	Enabled	Enabled	8 dB	-80 dB
13	Enabled	Enabled	Enabled	None	None
14	Enabled	Enabled	Enabled	None	None
15	Enabled	Enabled	Enabled	8 dB	None
16	Enabled	Enabled	Enabled	16 dB	None

- **Adaptive Noise Immunity:** Adjust noise and spur immunity levels based on PHY errors.
- **Preemption mode:** The radio stops current reception and restarts the receiver when a new signal which is above the threshold of the current signal is found. This allows the radio to switch signals when it locks onto interference or weaker 802.11 signal, when a valid 802.11 signal with a higher signal strength is detected.
- **Low Noise Amplifier:** Enables radio saturation at lower signal levels resulting in better performance in the presence of interference. Disabling LNA avoids radio saturation at lower signal levels. However, it may reduce range and throughput.
- **Interference Sensitivity Reduction:** Reduces the sensitivity to both Wi-Fi and non Wi-Fi interference signals. This makes the radio deaf to signals in which the SNR is below the threshold.
- **Force Noise Floor (for 2.4 GHz radio only):** Forces the radio to use the configured value as the absolute noise floor value. This makes the radio ignore signals of weaker amplitude.

Command History

Release	Modification
ArubaOS 8.11.0.0	The frame-bursting-mode and rts-mode parameters were introduced.
ArubaOS 8.10.0.0	The <code>airmatch-mode-aware</code> parameter was added.
ArubaOS 8.8.0.0	The <code>iot-coex-enable</code> parameter was added.
ArubaOS 8.4.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>high-efficiency-enable <radio></code> ■ <code>assoc-boost</code>
ArubaOS 8.1.0.0	The following parameters were added: <ul style="list-style-type: none"> ■ <code>deploy-hour</code> ■ <code>eirp-offset</code> ■ <code>energy-detect-threshold</code> ■ <code>minimum-channel-bandwidth</code>
ArubaOS 8.0.0.0	Command introduced.

  flsr-high-wm <percent>
  flsr-low-wm <percent>
  fnur-high-wm <percent>
  fnur-low-wm <percent>
  frer-high-wm <percent>
  frer-low-wm <percent>
  frr-high-wm <percent>
  frr-low-wm <percent>
  no ...
```

Description

This command configures the event thresholds profile. The event threshold profile configures Received Signal Strength Indication (RSSI) metrics. When certain RF parameters are exceeded, these events can signal excessive load on the network, excessive interference, or faulty equipment. This profile and many of the detection parameters are disabled (value is 0) by default.

Parameter	Description
<profile>	Name of this instance of the profile. The name must be 1-63 characters. default
bwr-high-wm	If bandwidth in an AP exceeds this value, a bandwidth exceeded condition exists. The value represents the percentage of maximum for a given radio. (For 802.11b, the maximum bandwidth is 7 Mbps. For 802.11 a and g, the maximum is 30 Mbps.) The recommended value is 85%. 0-100 0%
bwr-low-wm	After a bandwidth exceeded condition exists, the condition persists until bandwidth drops below this value. The recommended value is 70%. 0-100 0%

Parameter	Description
clone	Name of an existing radio profile from which parameter values are copied.
detect-frame-rate-anomalies	Enable or disables detection of frame rate anomalies. disabled
fer-high-wm	If the frame error rate (as a percentage of total frames in an AP) exceeds this value, a frame error rate exceeded condition exists. The recommended value is 16%. 0-100 0%
fer-low-wm	After a frame error rate exceeded condition exists, the condition persists until the frame error rate drops below this value. The recommended value is 8%. 0-100 0%
ffr-high-wm	If the frame fragmentation rate (as a percentage of total frames in an AP) exceeds this value, a frame fragmentation rate exceeded condition exists. The recommended value is 16%. 0-100 16%
ffr-low-wm	After a frame fragmentation rate exceeded condition exists, the condition persists until the frame fragmentation rate drops below this value. The recommended value is 8%. 0-100 8%
flsr-high-wm	If the rate of low-speed frames (as a percentage of total frames in an AP) exceeds this value, a low-speed rate exceeded condition exists. This could indicate a coverage hole. The recommended value is 16%. 0-100 16%
flsr-low-wm	After a low-speed rate exceeded condition exists, the condition persists until the percentage of low-speed frames drops below this value. The recommended value is 8%. 0-100 8%

Parameter	Description
fnur-high-wm	If the non-unicast rate (as a percentage of total frames in an AP) exceeds this value, a non-unicast rate exceeded condition exists. This value depends upon the applications used on the network. 0-100 0%
fnur-low-wm	After a non-unicast rate exceeded condition exists, the condition persists until the non-unicast rate drops below this value. 0-100 0%
frer-high-wm	If the frame receive error rate (as a percentage of total frames in an AP) exceeds this value, a frame receive error rate exceeded condition exists. The recommended value is 16%. 0-100 16%
frer-low-wm	After a frame receive error rate exceeded condition exists, the condition persists until the frame receive error rate drops below this value. The recommended value is 8%. 0-100 8%
frr-high-wm	If the frame retry rate (as a percentage of total frames in an AP) exceeds this value, a frame retry rate exceeded condition exists. The recommended value is 16%. 0-100 16%
frr-low-wm	After a frame retry rate exceeded condition exists, the condition persists until the frame retry rate drops below this value. The recommended value is 8%. 0-100 8%
no	Negates any configured parameter.

Example

The following command configures an event threshold profile:

```
(host)[node](config) #rf event-thresholds-profile et1
```

```
detect-frame-rate-anomalies
```

Command History

rf ht-radio-profile

```
rf ht-radio-profile <profile>
  40MHz-intolerance
  bss-color <bss-color>
  bss-color-switch-count
  clone <profile>
  csd-override
  honor-40MHz-intolerance
  no
  vht-bw-signaling
  vht-txbf-sounding-interval
```

Description

This command configures high-throughput AP radio settings. High-throughput features use the IEEE 802.11n standard, which supports 40 MHz channels and operates in both the 2.4 GHz and 5 GHz frequency bands.

Most transmissions to high throughput (HT) stations are sent through multiple antennas using cyclic shift diversity (CSD). When you enable the disable-diversity-spreading parameter, CSD is disabled and only one antenna transmits data, even if they are being sent to high-throughput stations. Use this feature to turn off antenna diversity when the AP must support legacy clients such as Cisco 7921g VoIP phones, or older 802.11g clients (e.g. Intel Centrino clients). Note, however, that enabling this feature can reduce overall throughput rates.

The ht-radio-profile you wish to use must be assigned to a dot11a and/or dot11g-radio-profile. You can assign the same profile or different profiles to the 2.4 GHz and 5 GHz frequency bands. See [rf dot11a-radio-profile on page 1196](#) and [rf dot11g-radio-profile on page 1228](#).

Parameter	Description
<profile>	Name of this instance of the profile. The name must be 1-63 characters. Default Options: <ul style="list-style-type: none">■ "Default-a" is generally used in association with high-throughput devices running on the 5 GHz frequency band, see rf dot11a-radio-profile on page 1196.■ "Default-g" is generally used in association with high-throughput devices running on the 2.4 GHz frequency band, see rf dot11g-radio-profile on page 1228.■ "Default" is generally used when the same ht-radio-profile is desired for use with both frequency bands. default-a, default-g, default
40MHz-intolerance	Controls whether or not APs using this radio profile will advertise intolerance of 40 MHz operation. By default, 40 MHz operation is allowed. disabled

Parameter	Description
<code>bss-color</code>	<p>Enables different colors for each category of BSSIDs. The Aruba 802.11ax based access points like AP-505, AP-515, AP-534, AP-535 and AP-555 support BSS coloring mechanism that helps identify the BSS from which a PLCP protocol data unit originates.</p> <p>NOTE: 530 Series and 550 Series access points can detect and change the color automatically if the same color is detected for another BSS on the same channel.</p> <p>NOTE: The value of 0 means auto mode, that is, the AP will set the color by itself, finding any available color.</p> <p>0-63 0</p>
<code>bss-color-switch-count</code>	<p>The number of times the BSS color switch announcements are sent in beacons before switching to a new color. Range: 0-100 and the default value is 10.</p> <p>0-100 10</p>
<code>clone</code>	<p>Name of an existing high-throughput radio profile from which parameter values are copied.</p>
<code>csd-override</code>	<p>Override Cyclic Shift Diversity for better interoperability.</p>
<code>honor-40MHz-intolerance</code>	<p>When enabled, the radio will stop using the 40 MHz channels if the 40 MHz intolerance indication is received from another AP or station.</p> <p>enabled</p>
<code>no</code>	<p>Negates any configured parameter.</p>
<code>vht-bw-signaling</code>	<p>Enable VHT Bandwidth Signaling RTS for better interoperability (802.11ac APs only).</p> <p>Disabled</p>
<code>vht-txbf-sounding-interval</code> < <code>vht-txbf-sounding-interval</code> >	<p>Time interval in milliseconds between updates of VHT Transmit Beamforming channel estimation. (802.11ac APs only).</p> <p>0</p>

Example

The following command configures an ht-radio-profile named "default-g" and enables 40MHz-intolerance:

```
(host) [node] (config) #rf ht-radio-profile default-g  
40MHz-intolerance
```

Command History

Release	Modification
ArubaOS 8.6.0.0	The <code>bss-color-switch-count</code> parameter was added.
ArubaOS 8.4.0.0	The <code>bss-color</code> parameter was added.
ArubaOS 8.0.0.0	Command introduced.

rf optimization-profile

```
rf optimization-profile <profile-name>
  clone <profile>
  handoff-assist
  low-rssi-threshold <number>
  no ...
  rssi-check-frequency <number>
  rssi-falloff-wait-time <number>
```

Description

This command configures the RF optimization profile.

Parameter	Description
<profile-name>	Name of this instance of the profile. The name must be 1-63 characters. default
clone	Name of an existing optimization profile from which parameter values are copied.
handoff-assist	Allows the controller to force a client off an AP when the RSSI drops below a defined minimum threshold. disabled
low-rssi-threshold	Minimum RSSI, above which deauth should never be sent. 1-255 10
no	Negates any configured parameter.
rssi-check-frequency	Interval, in seconds, to sample RSSI. 9-255 seconds 3 seconds
rssi-falloff-wait-time <number>	Number of times the detected client RSSI level must fall below the minimum RSSI threshold the before the AP sends a deauthorization message to the client. The maximum value is 8 times. 0-8 4

Example

The following command configures an RF optimization profile:

```
(host)[node](config) #rf optimization-profile Angela1
(host)[node](RF Optimization Profile "Angela1") #rssi-falloff-wait-time 3
(host)[node](RF Optimization Profile "Angela1") #rssi-check-frequency 2
```

rf spectrum-profile

```
rf spectrum-profile <profile-name>
  age-out audio|bluetooth|cordless-ff-phone|cordless-fh-base|cordless-fh-
  network|generic-ff|generic-fh|microwave|microwave-
  inverter|unknown|video|wifi|xbox
  channel
  clone <source>
  fft-dwell-time-ap
  fft-format
  fft_capture_ip
  filter-channel
  no ...
  no-wifi-fft
```

Description

Define the device ageout times used by a spectrum monitor, or hybrid AP radio. The Spectrum Analysis software module provides visibility into RF coverage, allowing you to troubleshoot RF interference and identify the 802.11 devices on the network. APs that gather spectrum data are called Spectrum Monitors, or *SMs*, and reference a spectrum profile that determines the band monitored by that SM radio. Use this profile to modify default device ageout times for spectrum monitors and hybrid APs using this profile.

For a list of APs that can be converted into a spectrum monitor or hybrid AP, refer to the Spectrum Analysis chapter of the ArubaOS User Guide.

Parameter	Description
age-out	Use the age-out parameter to define the number of seconds for which a specific device type must stop sending a signal before the spectrum monitor considers that device no longer active on the network.
audio	Some audio devices such as wireless speakers and microphones also use fixed frequency to continuously transmit audio. These devices are classified as Fixed Frequency (Audio). 5-65535 seconds 10 seconds
bluetooth	Bluetooth devices. Note that this setting is applicable to 2.4GHz spectrum monitor radios only. 5-65535 seconds 25 seconds

Parameter	Description
cordless-ff-phone	<p>Some cordless phones use a fixed frequency to transmit data (much like the fixed frequency video devices). These devices are classified as Fixed Frequency (Cordless Phones).</p> <p>5-65535 seconds</p> <p>10 seconds</p>
cordless-fh-base	<p>Frequency hopping cordless phone base units transmit periodic beacon-like frames at all times. When the handsets are not transmitting (i.e., no active phone calls), the cordless base is classified as Frequency Hopper (Cordless Base).</p> <p>5-65535 seconds</p> <p>240 seconds</p>
cordless-fh-network	<p>When there is an active phone call and one or more handsets are part of the phone conversation, the device is classified as Frequency Hopper (Cordless Network). Cordless phones may operate in 2.4 GHz or 5 GHz bands. Some phones use both 2.4 GHz and 5 GHz bands (for example, 5 GHz for Base-to-handset and 2.4 GHz for Handset-to-base). These phones may be classified as unique Frequency Hopper devices on both bands.</p> <p>5-65535 seconds</p> <p>60 seconds</p>
generic-ff	<p>All fixed frequency devices that do not fall into one of the other categories are classified as Fixed Frequency (Other). Note that the RF signatures of the fixed frequency audio, video and cordless phone devices are very similar and that some of these devices may be occasionally classified as Fixed Frequency (Other).</p> <p>5-65535 seconds</p> <p>10 seconds</p>
generic-fh	<p>When the classifier detects a frequency hopper that does not fall into one of the above categories, it is classified as Frequency Hopper (Other). Some examples include IEEE 802.11 FHSS devices, game consoles and cordless/hands-free devices that do not use one of the known cordless phone protocols.</p> <p>5-65535 seconds</p> <p>25 seconds</p>

Parameter	Description
generic-interferer	<p>Any non-frequency hopping device that does not fall into one of the other categories described in this table is classified as a Generic Interferer. For example a Microwave-like device that does not operate in the known operating frequencies used by the Microwave ovens may be classified as a Generic Interferer. Similarly wide-band interfering devices may be classified as Generic Interferers.</p> <p>5-65535 seconds 30 seconds</p>
lteu	<p>LTE-U Fixed Frequency devices</p> <p>5-65535 seconds 10 seconds</p>
microwave	<p>Common residential microwave ovens with a single magnetron are classified as a Microwave. These types of microwave ovens may be used in cafeterias, break rooms, dormitories and similar environments. Some industrial, healthcare or manufacturing environments may also have other equipment that behave like a microwave and may also be classified as a Microwave device. Note that this setting is applicable to 2.4GHz spectrum monitor radios only.</p> <p>5-65535 seconds 15 seconds</p>
microwave-inverter	<p>Some newer-model microwave ovens have the inverter technology to control the power output and these microwave ovens may have a duty cycle close to 100%. These microwave ovens are classified as Microwave (Inverter). Dual-magnetron industrial microwave ovens with higher duty cycle may also be classified as Microwave (Inverter). As in the Microwave category described above, there may be other equipment that behave like inverter microwaves in some industrial, healthcare or manufacturing environments. Those devices may also be classified as Microwave (Inverter).</p> <p>5-65535 seconds 15 seconds</p>
video	<p>Video transmitters that continuously transmit video on a single frequency are classified as Fixed Frequency (Video). These devices typically have close to a 100% duty cycle. These types of devices may be used for video surveillance, TV or other video distribution, and similar applications.</p> <p>5-65535 seconds 60 seconds</p>

Parameter	Description
wifi	Wi-Fi devices. 5-65535 seconds 600 seconds
xbox	The Microsoft Xbox device uses a frequency hopping protocol in the 2.4 GHz band. These devices are classified as Frequency Hopper (Xbox). Note that this setting is applicable to 2.4GHz spectrum monitor radios only. 5-65535 seconds 25 seconds
channel <channel>	Scan this channel for spectrum FFT.
clone <source>	Make a copy of an existing spectrum profile. 600 seconds
fft-dwell-time-ap	Specify the number of msec FFTs that will be enabled in hybrid mode (802.11ac APs only). Range: 5 - 900 msec. . 5-900 milliseconds 20 millisecond
fft-format	Specify one of the following power format of frequency bins for FFTs on QCA APs with V2 FFT format: <ul style="list-style-type: none"> 0: linear magnitude 1: log magnitude
fft_capture_ip <fft_capture_ip>	Specify the IP address where the AP sends the captured FFT samples.
filter-channel <filter-channel>	Specify the channel for which the data is to be passed to the classifier.
no	Remove a spectrum profile or negate a configured parameter.
no-wifi-fft	Specify weather the WiFi packets should be displayed in FFT charts. <ul style="list-style-type: none"> 0 : Display WiFi. 1 : Do not display WiFi.

Example

The following command creates the spectrum profile **spectrum2**.

```
(host)[node](config) #rf spectrum-profile spectrum2
```

Related Commands

Command	Description
show ap mesh-ht-ssid-profile	Shows a spectrum profile used by the spectrum analysis feature.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	RF Protect license.	Config mode on Mobility Conductor.

router mobile

router mobile

Description

This command enables Layer-3 (IP) mobility on a controller. IP mobility is disabled by default on the controller. This command must be executed on all controllers(master/ conductor and local) that need to provide support for layer-3 roaming in a mobility domain. You can enable or disable IP mobility on a virtual AP profile with the `wlan virtual-ap` command (IP mobility is enabled by default in a virtual AP profile).

It is recommended to reboot the controller every time you enable or disable IP mobility.

Example

This command enables IP mobility:

```
(host) [mynode] (config) #router mobile
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

router ospf

```
router ospf
  aggregate-route rapng-vpn <addr> <mask>
  area <area-id>
    default-cost <cost>
    no [default-cost | nssa | stub]
    nssa [default-information-originate | no-redistribution | no-summary]
    stub [no-summary]
  default-information originate always
  redistribute
    ike-overlay
    loopback
    rapng-vpn
    static
    vlan [add <vlan-ids> | remove <vlan-ids> | <vlan-ids>]
  router-id <rtr-id>
  subnet exclude <addr> <mask>
```

Description

This command configures OSPF configuration for the upstream router. This command is only available in the Config mode. OSPFv2 is a dynamic Interior Gateway routing Protocol (IGP) based on IETF RFC 2328. The OSPF implementation allows managed devices to deploy effectively in a Layer 3 topology.

Parameter	Description
aggregate-route rapng-vpn <addr> <mask>	Configures the aggregate route information for specified IP address and subnet mask and redistributes RAPNG VPN address.
area <area-id>	Configures OSPF area for specified area ID (IP address).
default-cost <cost>	Configures summary default-cost of a NSSA/stub area. 0-16777215
no [default-cost nssa stub]	Removes configured default-cost of NSSA/stub, NSSA, or stub.
nssa [default-information-originate no-redistribution no-summary]	Configures origination of type 7 default into NSSA area, sets NSSA area for no distribution into this NSSA area, or stops sending of summary LSA into this NSSA area.
stub [no-summary]	Configures an area as stub area and stops sending summary LSA into this area.

Parameter	Description
<code>default-information originate always</code>	Configures distribution of default information by distributing a default route.
<code>redistribute</code>	Redistributes the route.
<code>ike-overlay</code>	Redistributes Ike overlay routes.
<code>loopback</code>	Redistributes loopback addresses.
<code>rapng-vpn</code>	Redistributes RAPNG VPN addresses.
<code>static</code>	Redistributes static IP routes.
<code>vlan [add <vlan-ids> remove <vlan-ids> <vlan-ids>]</code>	Redistributes VLAN user subnet, adds user VLANs to list, or removes user VLANs from list.
<code>router-id <rtr-id></code>	Configures router ID for specified IP address
<code>subnet exclude <addr> <mask></code>	Configures IP address and subnet mask that OSPF will not advertise

Example

The following example configures an IP address 192.0.2.1 and subnet mask 255.0.255.255 that OSPF will not advertise:

```
(host) [mynode] (config) #router ospf subnet exclude 192.0.2.1 255.0.255.255
```

Command History

routing-policy-map

```
routing-policy-map
  branch <XX:XX:XX:XX:XX:XX> access-list <STRING>
  role <STRING> access-list <STRING>
```

Description

This command associates a routing ACL with a specific user role on a managed device. The commands to associate an access list to a user role vary, depending upon the type of access list being associated to that role. Ethertype, MAC, and session ACLs are applied globally across all managed devices, but routing access lists may vary between locations, so they are mapped to a user role in a local configuration setting.

In an environment where an IPsec map defines the connections between the managed device and Mobility Conductor, the global ACL **master/ conductor -boc-traffic** is applied to all IPsec maps between the managed device and Mobility Conductor. If any managed device requires a different ACL, issue the command `routing-policy-map branch <mac-addr> access-list <acl>` on that managed device to associate a different ACL to the L3 GRE tunnel between that one managed device and Mobility Conductor. This local setting will override the global settings defined in the **master/ conductor -boc-traffic** ACL.

Parameter	Description
branch <XX:XX:XX:XX:XX:XX>	By default, when a branch office deployment uses IPsec maps to define the connections between each branch office managed device and its Mobility Conductor, the global ACL master-boc-traffic is applied to those IPsec maps. Use this command to apply a local ACL to the GRE tunnel between a specific branch office managed device and its Mobility Conductor, overriding the default master/ conductor -boc-traffic ACL.
role <STRING>	Name of the user role to be associated with the specified routing ACL.
access-list <STRING>	Name of the route ACL to be associated to the specified user role.

Example

The following example maps a user role to a routing ACL.

```
(host)[node](config) #routing-policy-map
role employee access-list branch1
```

To associate the user role with an ethertype, MAC or session ACL, use the command `user-role <role> access-list eth|mac|session <acl>`.

```

Description

This command is used by the migration tool to export and import migration data from controllers in ArubaOS 6.x deployments to ArubaOS 8.x deployment.

Parameter	Description
dbupdate	Update the database entries for standalone system.
downgrade	Downgrade the databases.
<ip>	IP Address for GAP or WMS database that has to be downgraded.
export	Exports the setup data into <i>/tmp/dbsync/migration/setupInfo.xml</i>
sc-ca-cert [self-signed-cert <custom-cert>]	(Optional) Specify the CA certificate to be sent to the managed device. You can specify one of the following certificates: <ul style="list-style-type: none">■ self-signed-cert—Self-signed CA certificate is exported into <i>/tmp/dbsync/migration/sc_ssc.pem</i>■ <custom-cert>—The specified custom certificate (<i>/flash/certmgr/TrustedCA/<custom-cert></i>) is exported into <i>/tmp/dbsync/migration/<custom-cert></i>
import <ip>	Runs the upgrade scripts on the configuration (<i>default.cfg</i>) stored in the specified IP address. The upgraded configuration is applied on Mobility Conductor.

scheduler-profile

```
scheduler-profile <profile>
  clone
  priority-map q0|q1|q2|q3 <que-prio-list>
  queue-weights q0|q1|q2|q3 <que-weight>
```

Description

Define a scheduler profile that associates priorities to four uplink queues.

Parameter	Description
<code>clone <profile></code>	Make a copy of an existing scheduler profile.
<code>priority map q0 q1 q2 q3 <que-prio-list></code>	Specify one or more priority levels (0-7) for each queue type (q0 through q3). Each of the seven priority levels must be supported by one of the four queues.
<code>queue-weights q0 q1 q2 q3 <que-weight></code>	(Optional) Enter the percentage of available bandwidth that should be made available to traffic in each of the four queues. If you do not specify a weight for each queue, the queue service is based exclusively on the priority of the queue, where the lower priority queues are not serviced until the higher priority queue is clear. With this option, the highest level priority is guaranteed as much bandwidth as possible, but there can be phases where the 2nd, 3rd and 4th priority queues may receive little or no bandwidth.

Example

ArubaOS supports minimum bandwidth guarantees per traffic class, and allows critical delay-sensitive applications like voice and video to use more bandwidth and/or be scheduled with higher priority. Each interface can be associated with a scheduler profile, that supports four queues with different priority levels. If you use session ACLs to define traffic policies on the managed device, you can use the scheduler profile to automatically associate these different priority levels assigned by these policies to a scheduler profile queue. The scheduler profile must be associated with an interface using the command `interface cellular|gigabitethernet <slot/module/port> transmit max-rate rate mbits <mbps> scheduler-profile <profile>`.

scs-local-custom-cert

```
scs-local-custom-cert [scs-local-mac <mac>] [ca-cert <ca>] [server-cert <sc>]  
[suite-b [gcm128] | [gcm256]]
```

Description

This command configures security for all master/ conductor -local control traffic using custom certificate.

Parameter	Description
scs-local-mac <mac>	Specifies MAC address of managed device.
ca-cert <ca>	Specifies CA certificate to use.
server-cert <sc>	Specifies server certificate to use.
suite-b	Specifies GCM-128 or GCM-256 suite B algorithm to use.

Example

The following example configures CA certificate **default_ca** and server certificate **default_server** for master/ conductor -local control traffic:

```
(host) [mynode] #scs-local-custom-cert scs-local-mac  
00:1a:1e:aa:bb:cc ca-cert default_ca server-cert default_server
```

secondary masterip/secondary conductorip

```
secondary masterip/secondary conductorip <secmasterip_val>/<seconductorip_val>  
[ipsec | ipsec-custom-cert | ipsec-factory-cert | vpn-ip]
```

Description

Use this command to add a secondary Mobility Conductor from the primary Mobility Conductor CLI. This command is allowed in the **/md** tree, both in device nodes and group nodes.

Parameter	Description
secmasterip_val/seconductorip_val	Configure the master IP address or FQDN.
ipsec <key>	IPSec key of length 64 bytes.
fqdn <local-fqdn>	The Local's FQDN (max 64 bytes) used in IKE. This is optional for a Dynamically addressed Local
interface vlan <id>	Vlan interface to initiate IKE. The switch IP will be used if the vlan is not specified.
peer-mac-1 <peermac-1>	Specify peer MAC string.
ipsec-custom-cert	Custom Cert-based IPSec secure communication between master/ conductor and local.
master-mac-1-c <mac-1-c>/ conductor-mac-1-c <mac-1-c>	Specify Master's/Conductor's MAC address.
ca-cert	Specify the CA certificate to use.
master-mac-2-c	Specify the redundant master's MAC address.
ipsec-factory-cert	Factory Cert-based IPSec secure communication between master / conductor and local.
master-mac-1/conductor-mac-1	Specify Master's/Conductor's MAC address.
vpn-ip <vpnip>	VPN concentrator's IP address or FQDN.

Example

The following command enables you to add a secondary Mobility Conductor.

```
(host) [md] (config) #secondary masterip
```

Related Commands

secondary masteripv6/secondary conductoripv6

```
secondary masteripv6/secondary conductoripv6 <secmasteripv6_val>/<seconductoripv6_val> [ipsec <KEY> {fqdn <local-fqdn>|interface <vlan> {<id>}}|masteripv4 <secmasteripv4_val>/<seconductoripv4_val>|peer-mac-1 <peermac-1> ipsec-custom-cert [master-mac-1-c <MAC>] ipsec-factory-cert [master-mac-1-c <MAC>] vpn-ipv6
```

Description

Use this command to add a secondary Mobility Conductor containing IPv6 address. This command allows the user to add a secondary Mobility Conductor from the primary Mobility Conductor CLI. This command is allowed in the **/md** tree, both in device nodes and group nodes.

Parameter	Description
secmasteripv6_val/<seconductoripv6_val>	Configure the secondary master ipv6 address or FQDN.
ipsec <KEY>	Configure the IPsec secure communication between master/ conductor and local controllers. The IPsec key is of length 64 bytes.
fqdn <local-fqdn>	Configure the local controller's FQDN (max 64 bytes) used in IKE. This is optional for a dynamically addressed device.
interface <vlan> {<id>}	Configure the VLAN interface to initiate IKE. The switch IP is used if the vlan is not specified.
masteripv4/conductoripv4 <secmasteripv4_val>/<seconductoripv4_val>	Configure the corresponding IPv4 address of secondary master/ conductor . The configuration of the masteripv4 <secmasteripv4_val> sub-parameter is optional in a native IPv6 deployment.
peer-mac-1 <peermac-1>	Specify the peer MAC string on the primary Mobility Conductor.

Parameter	Description
<code>ipsec-custom-cert</code>	Custom certificate-based IPsec secure communication between master/ conductor and local controllers.
<code>master-mac-1-c <MAC>/conductor-mac-1-c<mac-1-c></code>	Specify the MAC address on the Mobility Conductor.
<code>ca-cert</code>	Specify the CA certificate to use.
<code>master-mac-2-c</code>	Specify the redundant master's MAC address.
<code>ipsec-factory-cert</code>	Factory certificate-based IPsec secure communication between master/ conductor and local controllers.
<code>master-mac-1-c <MAC>/conductor-mac-1-c <MAC></code>	Specify the MAC address on the Mobility Conductor.
<code>vpn-ipv6</code>	VPN concentrator's IPv6 address or FQDN.

Example

The following command enables you to add a secondary Mobility Conductor.

```
(host) [mynode] (config) #secondary masteripv6/secondary conductoripv6
```

The following example configures the managed device with an IPsec pre-shared key on the secondary Mobility Conductor:

```
(host) *[mynode] (config) #secondary masteripv6/secondary conductoripv6
2021:1:1:145::109 ipsec itsabug peer-mac-1 00:0C:29:60:92:E2 peer-mac-2
00:15:5D:14:1F:06 interface vlan 47 masteripv4 10.16.145.109
```

The following example configures the managed device with a factory-installed certificate on the secondary Mobility Conductor:

```
(host) *[mynode] (config) #secondary masteripv6/secondary conductoripv6
2001:78::245 ipsec-factory-cert master-mac-1 20:4c:03:0e:e1:68 interface-f
vlan-f 79 masteripv4 10.15.78.245
```

The following command configures the managed device terminating through VPNC with a factory-installed certificate on the secondary Mobility Conductor:

```
(host) *[mynode] (config) #secondary masteripv6/secondary conductoripv6
2021:1:1:145::109 vpn-ipv6 2001:192:192::8 ipsec-factory-cert vpn-mac-1
00:0b:86:b6:c7:07 interface vlan 172 masteripv4 10.16.145.109
```

The following command configures the managed device terminating through VPNC with a custom-installed certificate on the secondary Mobility Conductor:

```
(host) *[mynode] (config) #secondary masteripv6/secondary conductoripv6
2021:1:1:167::254 vpn-ipv6 2001:192:192::11 ipsec-custom-cert vpn-mac-1-c
00:0b:86:b6:c7:07 ca-cert-v BOC-CA server-cert-v BOC_cert interface vlan 172
masteripv4 10.16.167.254
```

service

```
service
  dhcp
  dhcpv6
  network-storage
  print-server
  scp
  no...
```

Description

This command enables the DHCP server on the controller. You can enable and configure DHCP, DHCPv6, network-storage, print server, or SCP in the controller to provide the following clients:

- **DHCP**: IP addresses to wireless clients if an external DHCP server is not available.
- **DHCPv6**: IPv6 addresses to wireless clients if an external DHCPv6 server is not available.
- **network-storage**: To provide access to the storage devices attached to the controller or managed device.
- **printer-server**: To provide access to printers attached to the controller .
- **SCP**: To provide SCP functionality on the controller itself rather than on an external server.

Parameter	Description
dhcp	Enables the DHCP server
dhcpv6	Enables the DHCPv6 server
network-storage	Enables the NAS service
print-server	Enables the printer service
scp	Enables the scp server functionality on the controller or managed device
no...	Removes the specific configuration

Example

The following command enables the DHCP server in the controller or managed device:

```
(host) [mynode] (config) #service dhcp
```

The following command enables the DHCPv6 server in the controller or managed device:

```
(host) [mynode] (config) #service dhcpv6
```

The following command enables the NAS services in the controller or managed device:

```
(host) [mynode] (config) #service network-storage
```

The following command enables the printer services in the controller or managed device:

```
(host) [mynode] (config) #service print-server
```

The following command enables the scp server functionality in the controller or managed device::

```
(host) [mynode] (config) #service scp
```

To disable the SCP server functionality on the controller, execute the following command:

```
(host) [mynode] (config) #no service scp
```

Related Commands

Command	Description

set-ikepsk-by-addr

set-ikepsk-by-addr <ip-addr>

Description

This command configures IKE PSK corresponding to an IP address.

Parameter	Description
<ip-addr>	Configures specified IP address to use to select IKE PSK.

Example

Access the CLI and use the following command to configure IKE PSK corresponding to IP address **192.0.2.1**:

```
(host) [mynode] #set-ikepsk-by-addr 192.0.2.1
```

set-trust-anchor

```
set-trust-anchor {self-signed | <ca-name>}
```

Description

This command configures a trust anchor for an access point.

Parameter	Description
self-signed	Configures self signed certificate as the trust anchor.
<ca-name>	Configures the specified trusted CA certificate as the trust anchor.

Example

Access the CLI and use the following command to configure self-signed certificate for an access point:

```
(host) [mynode] #set-trust-anchor self-signed
```

show aaa accounting tacacs

show aaa accounting tacacs

Description

This command displays TACACS+ data for your controller if you have previously configured a TACACS+ server and server group. The output includes the current TACACS+ accounting mode (enabled or disabled), and the name of the TACACS+ server group.

Example

The output of the `show aaa accounting tacacs` command displays configuration information for a TACACS+ accounting server. The output of this command includes the following parameters:

```
(host) #show aaa accounting tacacs
TACACS Accounting Configuration
-----
Parameter      Value
-----
Mode            Enabled
Commands       configuration
Server-Group   tacacs1
```

Parameter	Description
Mode	Shows whether this server group is Enabled or Disabled .
Commands	Displays the types of commands that are reported to the TACACS server group. <ul style="list-style-type: none">▪ action reports action commands only.▪ all reports all commands.▪ configuration reports configuration commands only▪ show reports show commands only
Server-Group	Shows whether this server is Enabled or Disabled .

Related Commands

Command	Description
aaa authentication-server tacacs	Configure the TACACS+ accounting feature.

Command	Description
aaa server-group	Add a configured authentication server to an ordered list in a server group, and configure server rules to derive a user role, VLAN ID or VLAN name from attributes returned by the server during authentication

Command History

show aaa alias-group

show aaa alias-group [<ag_name>]

Description

This command shows an alias-group settings.

Parameter	Description
<ag_name>	Shows settings of specified alias-group.

Example

The following example shows the list of alias-groups:

```
(host) [mynode] #show aaa alias-group

Alias Group List
-----
Name   References  Profile Status
-----
default 2

Total:1
```

Related Commands

show aaa authentication all

```
show aaa authentication all
```

Description

Show authentication statistics for your managed device, including authentication methods, successes and failures. This command displays a general overview of authentication statistics. To view authentication information for specific profiles such as a captive-portal, MAC or 801.X authentication profile, issue the commands specific to those features.

Example

The output of this command displays an authentication overview for your managed device, including the authentication methods used, and the numbers of successes or failures for each method. This example shows the numbers of authentication successes and failures for a managed device using TACACS+ and RADIUS authentication methods.

```
(host) #show aaa authentication all

Auth Method Statistics
-----
Method   Success  Failures
-----  -
tacacs   12       2 Radius
```

Related Commands

Command	Description
aaa authentication wispr	Configure WISPr authentication values on your Mobility Conductor.

show aaa authentication captive-portal

```
show aaa authentication captive-portal [<profile-name>]
```

Description

This command shows configuration information for captive portal authentication profiles. Issue this command without the `<profile-name>` parameter to display the entire Captive Portal Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

If you do not yet have any captive portal authentication profiles defined, use the command [aaa authentication captive-portal](#) to configure your captive portal profiles.

Parameter	Description
<code><profile-name></code>	The name of an existing captive portal authentication profile.

Examples

This first example shows that there are three configured captive portal profiles in the Captive Profile Authentication Profile List. The **References** column lists the number of other profiles with references to a captive portal authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication captive-portal

Captive Portal Authentication Profile List
-----
Name           References  Profile Status
----           -
c-portal       2
remoteuser                    1
portall1                    1

Total: 4
```

Include a captive portal profile name to display a complete list of configuration settings for that profile. The example below shows settings for the captive portal profile `portall1`.

```
Captive Portal Authentication Profile "portall1"
-----
Parameter                               Value
-----
Default Role                             guest
```

```

Default Guest Role      guest
Server Group           default
Redirect Pause         10 sec
User Login             Enabled
Guest Login            Disabled
Logout popup window    Enabled
Use HTTP for authentication Disabled
Logon wait minimum wait 5 sec
Logon wait maximum wait 10 sec
logon wait CPU utilization threshold 60 %
Max Authentication failures 0
Show FQDN              Disabled
Authentication Protocol PAP
Login page             /auth/index.
Welcome page          /auth/welcom
Show Welcome Page     Yes
Add switch IP address in the redirection URL Disabled
Adding user vlan in redirection URL Disabled
Add a controller interface in the redirection URL N/A
Allow only one active user session Disabled
White List/Allow List N/A
Black List/Deny List  N/A
Show the acceptable use policy page Disabled
User idle timeout      N/A
Redirect URL           N/A
Bypass Apple Captive Network Assistant Disabled
URL Hash Key          *****

```

The output of this command includes the following parameters:

Parameter	Description
Default Role	Role assigned to the captive portal user upon login.
Default Guest Role	Guest role assigned to the captive portal user upon login.
Server Group	Name of the group of servers used to authenticate captive portal users.
Redirect Pause	Time, in seconds, that the system remains in the initial welcome page before redirecting the user to the final web URL. If set to 0, the welcome page displays until the user clicks on the indicated link.
User Login	Shows whether the profile has enabled or disabled captive portal with authentication of user credentials.

Parameter	Description
Guest Login	Shows whether the profile has enabled or disabled captive portal guest login without authentication.
Logout popup window	Shows whether the profile has enabled or disabled a pop-up window that allows a user to log out. If this is disabled, the user remains logged in until the user timeout period has elapsed or the station resets.
Use HTTP for authentication	Shows whether the profile has enabled or disabled the ability to use the HTTP protocol to redirect users to the captive portal page.
Logon wait minimum wait	Minimum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high.
Logon wait maximum wait	Maximum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high.
logon wait CPU utilization threshold	CPU utilization percentage above which the logon wait interval is applied when directing a captive portal user with the logon page.
Max Authentication failures	Maximum number of authentication failures before the user is blacklisted/denylisted.
Show FQDN	If enabled, the user can see and select the fully-qualified domain name (FQDN) on the captive portal login page.
Authentication Protocol	This parameter specifies the type of authentication required by this profile, PAP is the default authentication type.
Login page	URL of the page that appears for the user logon.
Welcome page	URL of the page that appears after logon and before the user is redirected to the web URL.

Parameter	Description
Add <code>controller</code> IP address in the redirection URL	If enabled, this option sends the controller's IP address in the redirection URL when external captive portal servers are used. An external captive portal server can determine the controller from which a request originated by parsing the 'switchip' variable in the URL.
Adding user <code>vlan</code> in redirection URL	Shows the user's VLAN ID sent in the redirection URL, if enabled
Add a <code>controller</code> interface in the redirection URL	Shows the IP address of a controller interface added to the redirection URL, if enabled.
Allow only one active user session	If enabled, only one active user session is allowed at any time. This feature is disabled by default.
White List/Allow List	Shows the configured whitelist/allowlist on an IPv4 or IPv6 network destination. The whitelist/allowlist contains authenticated websites that a guest can access.
Black List/Deny List	Shows the configured blacklist/denylist on an IPv4 or IPv6 network destination. The blacklist/denylist contains websites (unauthenticated) that a guest cannot access.
Show the acceptable use policy page	If enabled, the captive portal page will show the acceptable use policy page before the user logon page. This feature is disabled by default.
User Idle Timeout	The user idle timeout for this profile. The valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.
<code>redirect-url <url></code>	URL to which an authenticated user will be directed.
URL hash key	If this value is set, the redirection URL is hashed using the defined hash key. The characters in the hash key are hidden in the output of this command

Related Commands

Command	Description
aaa authentication captive-portal	This command is used to configure the parameters displayed in the output of this show command.

Command History

Version	Modification
ArubaOS 8.9.0.0	The following changes were introduced: All instances of <code>blacklist</code> have been replaced with <code>denylist</code> . All instances of <code>whitelist</code> have been replaced with <code>allowlist</code> .

show aaa authentication captive-portal customization

show aaa authentication captive-portal customization <profile-name>

Description

Display customization settings for a captive portal profile. This command shows how a captive portal profile has been customized with non-default configuration settings. If you do not yet have any captive portal authentication profiles defined, use the command [aaa authentication captive-portal](#) to configure your captive portal profiles.

Parameter	Description
<profile-name>	The name of an existing captive portal authentication profile.

Example

The output of the following command shows how the captive portal profile *c-portal* has been customized. If an individual parameter has not been changed from its default settings, its value entry will be blank.

```
(host) #show aaa authentication captive-portal customization c-portal
Captive-Portal Customization
-----
Parameter                Value
-----
Login page design theme   3
Login page logo image
Login page text URL       /flash/upload/custom/ssu-guest-cp/logintext.html
Login policy text URL     /upload/custom/ssu-guest-cp/acceptableusepolicy.html
Custom page background color
Custom page background image /upload/custom/default/auth-slider-1.gif
```

The output of this command includes the following parameters:

Parameters	Description
Login page design theme	Indicates whether the controller is using one of the two predefined login page designs (1 or 2) or has a custom background (3).
Login page logo image	Path and filename for a custom captive portal logo. This option is only available if the controller has a predefined login design.
Login page text	Path and filename of the page that appears for the user logon.

Parameters	Description
Login policy text	Path and filename of the page that displays user policy text.
Custom page background color	Hexadecimal value for a custom background color. This option is only available if the controller has a custom login page design theme.
Custom page background image	Path and filename for a custom JPEG captive portal background image. This option is only available if the controller has a custom login page design theme.

show aaa authentication downloaded-cp-profiles

```
show aaa authentication downloaded-cp-profiles
```

Description

This command shows the downloaded CP profiles. Issue this command to display the entire downloaded CP profile list, including profile status and the number of references to each profile. Include a profile name to display detailed configuration information for that profile.

Example

Include a captive portal profile name to display a complete list of configuration settings for that profile. The example below shows settings for the captive portal authentication profile cp2-d8941734:

```
Captive Portal Authentication Profile "cp2-d8941734"
-----
Parameter                               Value
-----
Default Role                             authenticated
Default Guest Role                       guest
Server Group                             cppm-rad-2
Redirect Pause                            10 sec
User Login                               Enabled
Guest Login                              Disabled
Logout popup window                      Enabled
Use HTTP for authentication              Disabled
Logon wait minimum wait                  5 sec
Logon wait maximum wait                  10 sec
logon wait CPU utilization threshold      60 %
Max Authentication failures                0
Show FQDN                                Disabled
Authentication Protocol                  PAP
Login page                               /auth/index.html
Welcome page                             /auth/welcome.html
Show Welcome Page                        Yes
Add switch IP address in the redirection URL Disabled
Adding user vlan in redirection URL       Disabled
Add a controller interface in the redirection URL N/A
Allow only one active user session        Disabled
White List                               N/A
Black List                               N/A
Show the acceptable use policy page       Disabled
User idle timeout                        -1
Redirect URL                             N/A
Bypass Apple Captive Network Assistant   Disabled
URL Hash Key                             *****

Total Downloaded CP profiles: 1
```

The output of this command includes the following parameters:

Parameter	Description
Default Role	Role assigned to the captive portal user upon login.
Default Guest Role	Guest role assigned to the captive portal user upon login.
Server Group	Name of the group of servers used to authenticate captive portal users.

Parameter	Description
Redirect Pause	Time, in seconds, that the system remains in the initial welcome page before redirecting the user to the final web URL. If set to 0, the welcome page displays until the user clicks on the indicated link.
User Login	Shows whether the profile has enabled or disabled captive portal with authentication of user credentials.
Guest Login	Shows whether the profile has enabled or disabled captive portal guest login without authentication.
Logout popup window	Shows whether the profile has enabled or disabled a pop-up window that allows a user to log out. If this is disabled, the user remains logged in until the user timeout period has elapsed or the station resets.
Use HTTP for authentication	Shows whether the profile has enabled or disabled the ability to use the HTTP protocol to redirect users to the captive portal page.
Logon wait minimum wait	Minimum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high.
logon wait maximum wait	Maximum time, in seconds, the user will have to wait for the logon page to pop up if the CPU load is high.
Logon wait CPU utilization threshold	CPU utilization percentage above which the logon wait interval is applied when directing a captive portal user with the logon page.
Max Authentication failures	Maximum number of authentication failures before the user is blacklisted/denylisterd.
Show FQDN	If enabled, the user can see and select the fully-qualified domain name (FQDN) on the captive portal login page.
Authentication Protocol	This parameter specifies the type of authentication required by this profile, PAP is the default authentication type.

Parameter	Description
Login page	URL of the page that appears for the user logon.
Welcome page	URL of the page that appears after logon and before the user is redirected to the web URL.
Add controller IP address in the redirection URL	If enabled, this option sends the controller's IP address in the redirection URL when external captive portal servers are used. An external captive portal server can determine the controller from which a request originated by parsing the 'switchip' variable in the URL.
Adding user vlan in redirection URL	Shows the user's VLAN ID sent in the redirection URL, if enabled
Add a controller interface in the redirection URL	Shows the IP address of a controller interface added to the redirection URL, if enabled.
Allow only one active user session	If enabled, only one active user session is allowed at any time. This feature is disabled by default.
White List	Shows the configured white list on an IPv4 or IPv6 network destination. The white list contains authenticated websites that a guest can access.
Black List	Shows the configured black list on an IPv4 or IPv6 network destination. The black list contains websites (unauthenticated) that a guest cannot access.
Show the acceptable use policy page	If enabled, the captive portal page will show the acceptable use policy page before the user logon page. This feature is disabled by default.
User Idle Timeout	The user idle timeout for this profile. The valid range is 30-15300 in multiples of 30 seconds. Enabling this option overrides the global settings configured in the AAA timers. If this is disabled, the global settings are used.
redirect-url <url>	URL to which an authenticated user will be directed.

Parameter	Description
URL hash key	If this value is set, the redirection URL is hashed using the defined hash key. The characters in the hash key are hidden in the output of this command
Total Downloaded CP profiles	Shows the total number of downloaded CP profiles.

show aaa authentication dot1x

```
show aaa authentication dot1x [<profile-name>|countermeasures]
```

Description

This command shows information for 802.1X authentication profiles. Issue this command without the **<profile-name>** or **countermeasures** options to display the entire 802.1X Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed dot1x authentication configuration information for that profile. The **countermeasures** option indicates whether the 802.1X profiles have been configured for WPA/WPA2 countermeasures. If countermeasures have not been configured, the output for this command will be blank.

Parameter	Description
<profile-name>	The name of an existing 802.1X authentication profile.
countermeasures	Reports if WPA/WPA2 Countermeasures have been enabled for 802.1X profiles. If enabled, the AP scans for message integrity code (MIC) failures in traffic received from clients.

Examples

The following example lists all dot1x authentication profiles. The **References** column lists the number of other profiles with references to a 802.1X authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined 802.1X profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication dot1x

802.1X Authentication Profile List
-----
Name           References  Profile Status
-----
default        2
default-psk    1           Predefined (editable)
dot1x          5
dot1xtest      0

Total:4
```

To display a complete list of parameters for an individual profile, include the <profile> parameter. The example below displays some of the profile details for the authentication profile pDotix.

```
(host) #show aaa authentication dot1x pDot1x

802.1X Authentication Profile "pDot1x"
-----
Parameter                                     Value
-----
Max authentication failures                    0
Enforce Machine Authentication                Disabled
Machine Authentication: Default Machine Role  guest
Machine Authentication Cache Timeout          24 hrs
Blacklist/Denylist on Machine Authentication Failure Disabled
Machine Authentication: Default User Role     guest
Interval between Identity Requests           30 sec
Quiet Period after Failed Authentication      30 sec
Reauthentication Interval                     86400 sec
Use Server provided Reauthentication Interval Disabled
Multicast Key Rotation Time Interval          1800 sec
Unicast Key Rotation Time Interval           900 sec
...
```

The output of the **show aaa authentication dot1x** command includes the following parameters:

Parameter	Value
Max authentication failures	Number of times a user can try to login with wrong credentials after which the user is blacklisted /denylisted as a security threat. Blacklisting /Denylisting is disabled if this parameter is set to 0.

Parameter	Value
Enforce Machine Authentication	Shows if machine authentication is enabled or disabled for Windows environments. If enabled, if enabled, either the machine-default-role or the user-default-role is assigned to the user, depending on which authentication is successful.
Machine Authentication: Default Machine Role	Default role assigned to the user after completing only machine authentication.
Machine Authentication Cache Timeout	The timeout period, in hours, for machine authentication. After this period passes, the user will have to re-authenticate.
Blacklist/Denylist on Machine Authentication Failure	If enabled, the client is blacklisted /denylisted if machine authentication fails.
Machine Authentication: Default User Role	Default role assigned to the user after 802.1X authentication.
Interval between Identity Requests	Interval, in seconds, between identity request retries

Parameter	Value
Quiet Period after Failed Authentication	Interval, in seconds, following failed authentication.
Reauthentication Interval	Interval, in seconds, between reauthentication attempts.
Use Server provided Reauthentication Interval	If enabled, 802.1X authentication will use the server-provided reauthentication period.
Multicast Key Rotation Time Interval	Interval, in seconds, between multicast key rotations.
Unicast Key Rotation Time Interval	Interval, in seconds, between unicast key rotations.
Authentication Server Retry Interval	Server group retry interval, in seconds.
Authentication Server Retry Count	The number of server group retries.
Framed MTU	Shows the framed MTU attribute sent to the authentication server.
Number of times ID-Requests are retried	Maximum number of times ID requests are sent to the client.
Maximum Number of Reauthentication Attempts	Maximum number of reauthentication attempts.

Parameter	Value
Maximum number of times Held State can be bypassed	Number of consecutive authentication failures which, when reached, causes the controller to not respond to authentication requests from a client while the controller is in a held state after the authentication failure.
Dynamic WEP Key Message Retry Count	Number of times unicast/multicast EAPOL key messages are sent to the client.
Dynamic WEP Key Size	Dynamic WEP key size, either 40 or 128 bits.
Interval between WPA/WPA2 Key Messages	Interval, in milliseconds, between each WPA key exchange. The allowed range of values is 1000-5000 msec, and the default value is 1000 msec.
Delay between EAP-Success and WPA2 Unicast Key Exchange	Show the delay interval between EAP-Success and unicast key exchanges, in msec. Range: 0-2000msec. Default: 0 (no delay).

Parameter	Value
Delay between WPA/WPA2 Unicast Key and Group Key Exchange	Interval, in milliseconds, between unicast and multicast key exchanges.
Time interval after which the PMKSA will be deleted	Show the PMKSA cache interval. Time interval in Hours. Range: 1-2000. Default: 8 hrs.
Delete Keycache upon user deletion Enabled	If enabled, the controller deletes the key cache entry when the user entry is deleted.
WPA/WPA2 Key Message Retry Count	Number of times WPA/WPA2 key messages are retried.
Multicast Key Rotation	Shows if multicast key rotation is enabled or disabled.
Unicast Key Rotation	Shows if unicast key rotation is enabled or disabled.
Reauthentication	If enabled, this option forces the client to do a 802.1X reauthentication after the expiration of the default timer for reauthentication. (The default value of the timer is 24 hours.)

Parameter	Value
Opportunistic Key Caching	If enabled, a cached pairwise master key (PMK) is derived with a client and an associated AP and used when the client roams to a new AP.
Validate PMKID	Shows if the Validate PMKID feature is enabled or disabled. When this option is enabled, the client must send a PMKID in the associate or reassociate frame to indicate that it supports OKC; otherwise, full 802.1X authentication takes place. (This feature is optional, since most clients that support OKC do not send the PMKID in their association request.)
Use Session Key	If enabled, the controller will use a RADIUS session key as the unicast WEP key.
Use Static Key	If enabled, the controller will use a static key as the unicast/multicast WEP key.
xSec MTU	Shows the size of the MTU for xSec.

Parameter	Value
Termination	Shows if 802.1X termination is enabled or disabled on the controller.
Termination EAP-Type	Shows the current Extensible Authentication Protocol (EAP) method, either EAP-PEAP or EAP-TLS.
Termination Inner EAP-Type	When EAP-PEAP is the EAP method, this parameter displays the inner EAP type.
Enforce Suite-B 128 bit or more security level Authentication	Shows if Suite-B 128 bit or more security level authentication enforcement is enabled or disabled.
Enforce Suite-B 192 bit security level Authentication	Shows if Suite-B 192 bit or more security level authentication enforcement is enabled or disabled.
Token Caching	If this feature enabled (and EAP-GTC is configured as the inner EAP method), token caching allows the controller to cache the username and password of each authenticated user.

Parameter	Value
Token Caching Period	Timeout period, in hours, for the cached information.
CA-Certificate	Name of the CA certificate for client authentication loaded in the controller.
Server-Certificate	Name of the Server certificate used by the controller to authenticate itself to the client.
TLS Guest Access	Shows if guest access for valid EAP-TLS users is enabled or disabled.
TLS Guest Role	User role assigned to EAP-TLS guest.
Ignore EAPOL-START after authentication	If enabled, the controller ignores EAPOL-START messages after authentication.
Handle EAPOL-Logoff	Shows if handling of EAPOL-LOGOFF messages is enabled or disabled.
Ignore EAP ID during negotiation	If enabled, the controller will ignore EAP IDs during negotiation.

Parameter	Value
WPA-Fast-Handover	Shows if WPA-fast-handover is enabled or disabled. This feature is only applicable for phones that support WPA.
Disable rekey and reauthentication for clients on call	Shows if the rekey and reauthentication features for voice-over-WLAN clients has been enabled or disabled.
Check certificate common name against AAA server	If enabled, this parameter verifies that the certificate's common name exists in the server. This parameter is disabled by default dot1x profiles.

show aaa authentication mac

```
show aaa authentication mac [<profile-name>]
```

Description

This command shows information for MAC authentication profiles. Issue this command without the

<profile-name> option to display the entire MAC Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed MAC authentication configuration information for that profile.

Parameter	Description
<profile-name>	The name of an existing MAC authentication profile.

Examples

The output of the example below shows one MAC authentication profiles, **default**, which is referenced once by other profiles. the **Profile Status** column is blank, indicating that the profile is user-defined. (If a profile is predefined, the value **Predefined** appears in the Profile Status column.)

```
(host) #show aaa authentication mac

MAC Authentication Profile List
-----
Name       References  Profile Status
----       -
default    1

Total:1
```

The following example displays configuration details for the MAC authentication profile "default," including the delimiter and case used in the authentication request, and the maximum number of times a client can fail to authenticate before it is blacklisted/denylister.

```
(host) #show aaa authentication mac default
MAC Authentication Profile "default"
-----
Parameter                               Value
-----
Delimiter                                 none
Case                                       lower
Max Authentication failures               0
Reauthentication                         Disabled
```

```
Reauthentication Interval          86400 sec
Use Server provided Reauthentication Interval Disabled
```

show aaa authentication mgmt

```
show aaa authentication mgmt
```

Description

This command displays administrative user authentication information, including management authentication roles and servers. Issue this command to identify the default management role assigned to authenticated administrative users, and the name of the group of servers used to authenticate these users.

Example

The output of the following example displays management authentication information for your controller.

```
(host) #show aaa authentication mgmt

Management Authentication Profile
-----
Parameter      Value
-----
Default Role   root
Server Group   ServerGroup1
Enable         Enabled
```

The output of the `show aaa authentication mgmt` command includes the following parameters:

Parameter	Description
Default Role	This parameter shows which of the following roles the controller uses for authentication management. <ul style="list-style-type: none">▪ root, the super user role (default).▪ guest-provisioning, guest provisioning role.▪ network-operations, network operator role.▪ read-only, read only role.▪ location-api-mgmt, location API management role.▪ no-access, no commands are accessible.
Server Group	The name of a server group.
Enable	The Enable parameter indicates whether or not this feature is enabled or disabled.

Related Commands

show aaa authentication stateful-ntlm

```
show aaa authentication stateful-ntlm [default|<profile-name>]
```

Description

This command shows the configuration settings of the stateful NT LAN Manager (NTLM) authentication profile. Issue this command without the <profile-name> parameter to display the entire stateful NTLM Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed Stateful NTLM authentication configuration information for that profile. Use this command to identify the default role assigned to users who have successfully authenticated using the NTLM authentication protocol, the name of the group of windows servers used to authenticate these users, and the NTLM authentication timeout period, in seconds.

Parameter	Description
default	Shows the configuration settings of the default NTLM authentication profile.
<profile-name>	Shows the configuration settings of the specified NTLM authentication profile.

Examples

The following example shows the configuration settings of the stateful NTLM authentication profile:

```
(host) [mynode] #show aaa authentication stateful-ntlm

Stateful NTLM Authentication Profile List
-----
Name                References  Profile Status
----                -
default             1
NTLMprofile1                1

Total:2
Two stateful NTLM authentication profiles, default and NTLMprofile1 are each
referenced once by other profiles. The blank Profile Status column indicates
that these profiles are both user-defined. If a profile is predefined, the
value Predefined appears in the Profile Status column.
The following example displays configuration details for the stateful NTLM
authentication profile "default".
(host) [node] #show aaa authentication stateful-ntlm default

Stateful NTLM Authentication Profile "default"
-----
```

```

Parameter      Value
-----      -
Default Role   guest
Server Group   default
Mode           Disabled
Timeout        10 sec

```

The output of this command includes the following parameters:

Parameter	Description
Default Role	This parameter shows the role assigned to NTLM authenticated users.
Server Group	The name of a windows server group.
Mode	The <code>Mode</code> parameter indicates whether or not this authentication profile is enabled or disabled.
Timeout	Timeout period for an authentication request, in seconds.

show aaa authentication stateful-dot1x

```
show aaa authentication stateful-dot1x [config-entries]
```

Description

This command shows the stateful configuration settings of 802.1X authentication for clients on non-Aruba APs. Issue this command to identify the default role assigned to the 802.1X user group, name of the group of RADIUS servers used to authenticate the 802.1X users, and the 802.1X authentication timeout period in seconds.

Parameter	Description
config-entries	Display details for the AP Server configuration list.

Example

The following example shows the stateful configuration settings of 802.1X authentication information:

```
(host) [mynode] #show aaa authentication stateful-dot1x

Stateful 802.1X Authentication Profile
-----
Parameter      Value
-----
Default Role   guest
Server Group   newgroup2
Timeout        10 sec
Mode           Enabled
```

The output of this command includes the following parameters:

Parameter	Description
Default Role	This parameter shows which role the controller uses for 802.1X authentication management.
Server Group	The name of a server group.
Timeout	Timeout period for an authentication request, in seconds.
Mode	The Mode parameter indicates whether or not this feature is enabled or disabled.

Include the `config-entries` parameter to this command to show the AP - Server Configuration List.

```
(host) [mynode] #show aaa authentication stateful-dot1x config-entries

AP-Server Configuration List
-----
Cfg-Name          AP-IP          Server  Shared-Secret
-----          -
cfg22             10.3.14.6     RADIUS1 secret-pwd
```

The output of this command includes the following parameters:

Parameter	Description
Cfg-Name	is a auto-generated name
AP-IP	IP address of the AP.
Server	Name of the authentication server.
Shared-Secret	Shared authentication secret.

show aaa authentication via auth-profile

```
show aaa authentication via auth-profile [<profile-name>]
```

Description

This command displays configuration settings for the VIA Authentication profile. Issue this command without the **<profile-name>** option to display the entire VIA Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed VIA authentication configuration information for that profile.

If you do not yet have any VIA authentication profiles defined, use the command [aaa authentication via auth-profile](#) to configure your VIA authentication profiles.

Parameter	Description
<profile-name>	The name of an existing VIA authentication profile.

Examples

This first example shows that there are three configured captive portal profiles in the Captive Profile Authentication Profile List. The **References** column lists the number of other profiles with references to a VIA authentication profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication via auth-profile

VIA Authentication Profile List
-----
Name       References  Profile Status
-----
default    0
via1       2
via2       1

Total:3
```

Include a VIA authentication profile name to display a complete list of configuration settings for that profile. The example below shows settings for the VIA authentication profile via1.

```
VIA Authentication Profile "via1"
-----
Parameter                               Value
-----
Default Role                             default-via-role
Server Group                             internal
Max Authentication failures               2
```

Description

VIA config for the MV office

The output of this command includes the following parameters:

Parameter	Description
Default Role	Role assigned to the captive portal user upon login.
Server Group	Name of the group of servers used to authenticate captive portal users.
Max Authentication failures	Maximum number of authentication failures before the user is blacklisted/denylisted.
Description	Description of the VIA authentication profile.

show aaa authentication via connection-profile

show aaa authentication via connection-profile [<profile-name>]

Description

This command displays configuration settings for the VIA connection profile. Issue this command without the <profile-name> option to display the entire VIA Connection profile list, including profile status and the number of references to each profile. Include a profile name to display detailed VIA connection configuration information for that profile.

If you do not yet have any VIA connection profiles defined, use the command [aaa authentication via connection-profile](#) to configure your VIA connection profiles.

Parameter	Description
<profile-name>	The name of an existing VIA connection profile.

Examples

This first example shows that there are three configured connection profiles in the Captive Profile Authentication Profile List. The **References** column lists the number of other profiles with references to a VIA connection profile, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #show aaa authentication via connection-profile

VIA Connection Profile List
-----
Name           References  Profile Status
----           -
connection_1   3
connection_2   1
default        0

Total:3
```

Include a connection profile name to display a complete list of configuration settings for that profile. The example below shows settings for the captive portal profile connection_1.

```
VIA Connection Profile "default"
-----
Parameter                               Value
-----
VIA Servers                               N/A
Client Auto-Login                         Enabled
```

```

VIA Authentication Profiles to provision N/A
Allow client to auto-upgrade Enabled
VIA tunneled networks N/A
Enable split tunneling Disabled
VIA Client WLAN profiles N/A
Allow client side logging Enabled
VIA IKE V2 Policy Default
VIA IKE Policy Default
Use Windows Credentials Enabled
Use l2 forwarding Enabled
Enable IKEv2 Disabled
Use Suite B Cryptography Disabled
IKEv2 Authentication method user-cert
VIA IPsec V2 Crypto Map default-ikev2-
dynamicmap/10000
VIA IPsec Crypto Map default-
dynamicmap/10000
Allow user to save passwords Enabled
Enable Supplicant Disabled
Enable FIPS Module Disabled
Auto-launch Supplicant Disabled
Lockdown All Settings Disabled
Domain Suffix in VIA Authentication Disabled
Enable Controllers Load Balance Disabled
Enable Domain Pre-connect Enabled
VIA Banner Message Reappearance Timeout(minutes) 60
VIA Client Network Mask 255.255.255.255
Validate Server Certificate Enabled
VIA Client DNS Suffix List N/A
VIA max session timeout 1440 min
VIA Logon Script N/A
VIA Logoff Script N/A
VIA Support E-Mail Address N/A
Maximum reconnection attempts 3
VIA external download URL N/A
Allow user to disconnect VIA Enabled
Content Security Gateway URL N/A
Comma seperated list of HTTP ports to be inspected
(apart from default port 80) N/A
Enable Content Security Services Disabled
Keep VIA window minimized Disabled
Block traffic until VPN tunnel is up Disabled
Block traffic rules N/A

```

The output of this command includes the following parameters:

Parameter	Description
VIA servers	Displays the following information about the VIA server: <ul style="list-style-type: none"> <i>controller Hostname/IP Address</i>: This is the public IP address or the DNS hostname of the VIA controller. Users will connect to

Parameter	Description
	<p>remote server using this IP address or the hostname.</p> <ul style="list-style-type: none"> ▪ controller Internal IP Address: This is the IP address of any of the VLAN interface IP addresses belongs to this controller. ▪ controller Description: This is a human-readable description of the controller.
Client Auto-Login	<p>Enable or disable VIA client to auto login and establish a secure connection to the controller. Default: Enabled</p>
VIA Authentication Profiles to provision	<p>This is the list of VIA authentication profiles that will be displayed to users in the VIA client.</p>
Allow client to auto-upgrade	<p>Enable or disable VIA client to automatically upgrade when an updated version of the client is available on the controller. Default: Enabled</p>
VIA tunneled networks	<p>A list of network destination (IP address and netmask) that the VIA client will tunnel through the controller. All other network destinations will be reachable directly by the VIA client.</p>
Enable split-tunneling	<p>Enable or disable split tunneling.</p> <ul style="list-style-type: none"> ▪ If enabled, all traffic to the VIA tunneled networks will go through the controller and the rest is just bridged directly on the client. ▪ If disabled, all traffic will flow through the controller. <p>Default: off</p>
Allow client-side logging	<p>Enable or disable client side logging. If enabled, VIA client will collect logs that can be sent to the support email-address for troubleshooting. Default: Enabled</p>
VIA Client WLAN profiles	<p>A list of VIA client WLAN profiles that needs to be pushed to the client machines that use Windows Zero Config (WZC) to configure or manage their wireless networks.</p>
VIA IKEv2 Policy	<p>A list of IPsec crypto maps that the VIA client uses to connect to the controller. These IPsec Crypto Maps are configured in the CLI using the <code>crypto-local ipsec-map <ipsec-map-name></code> command.</p>

Parameter	Description
VIA IKE Policy	List of IKE policies that the VIA Client has to use to connect to the controller.
Use Windows Credentials	Enable or disable the use of the Windows credentials to login to VIA. If enabled, the SSO (Single Sign-on) feature can be utilized by remote users to connect to internal resources. Default: Enabled
Use l2 forwarding	Enable or disable the forwarding of Layer-2 GRE tunnel by VIA client.
Enable IKEv2	Select this option to enable or disable the use of IKEv2 policies for VIA.
Use Suite B Cryptography	Select this option to use Suite B cryptography methods. You must install the Advanced Cryptography license to use the Suite B cryptography.
IKEv2 Authentication method	List of all IKEv2 authentication methods.
VIA IPsec V2 Crypto Map	List of all IPsec V2 that the VIA client uses to connect to the controller.
VIA IPsec Crypto Map	List of IPsec Crypto Map that the VIA client uses to connect to the controller. These IPsec Crypto Maps are configured in CLI using the <code>crypto-local ipsec-map <ipsec-map-name></code> command.
Allow user to save passwords	Enable or disable users to save passwords entered in VIA. Default: Enabled
Enable Supplicant	If enabled, VIA starts in bSec mode using L2 suite-b cryptography. This option is disabled by default.
Enable FIPS Module	Shows if the VIA (Federal Information Processing Standard) FIPS module is enabled, so VIA checks for FIPS compliance during startup. This option is disabled by default.
Auto-Launch Supplicant	Select this option to automatically connect to a configured WLAN network.
Lockdown All Settings	If enabled, all user options on the VIA client are disabled.

Parameter	Description
Domain Suffix in VIA Authentication	Enables a domain suffix on VIA Authentication, so client credentials are sent as <i>domainname\username</i> instead of just <i>username</i> .
Enable controllers Load Balance	This option allows the VIA client to failover to the next available selected randomly from the list as configured in the VIA Servers option. If disabled, VIA will failover to the next in the sequence of ordered list of VIA Servers.
Enable Domain Pre-Connect	This option allows users with lost or expired passwords to establish a VIA connection to corporate network. This option authenticates the user's device and establishes a VIA connection that allows users to reset credentials and continue with corporate access.
VIA Banner Reappearance Timeout	The maximum time (in minutes) allowed before the VIA login banner reappears. Default: 1440 min
VIA Client Network Mask	The network mask that has to be set on the client after the VPN connection is established. Default: 255.255.255.255
Validate Server Certificate	Enable or disable VIA from validating the server certificate presented by the controller. Default: Enabled
VIA Client DNS Suffix List	The DNS suffix list (comma separated) that has be set on the client once the VPN connection is established. Default: None.
VIA max session timeout	The maximum time (minutes) allowed before the VIA session is disconnected. Default: 1440 min
VIA Logon Script	Name of the logon script that must be executed after VIA establishes a secure connection. The logon script must reside in the client computer.
VIA Logoff Script	Name of the log-off script that must be executed after the VIA connection is disconnected. The logoff script must reside in the client computer.
VIA Support E-mail Address	The support e-mail address to which VIA users will send client logs. Default: None.

Parameter	Description
Maximum reconnection attempts	The maximum number of re-connection attempts by the VIA client due to authentication failures. Default: 3
VIA external download URL	End users will use this URL to download VIA on their computers.
Allow user to disconnect VIA	Enable or disable users to disconnect their VIA sessions. Default: Enabled
Content Security Gateway URL	If split-tunnel forwarding is enabled, access to external (non-corporate) web sites will be verified by the specified content security service provider.
Comma Separated List of HTTP Ports	Traffic from the specified ports will be verified by the content security service provider.
Enable Content Security Services	Select this check box to enable content security service. You must install the Content Security Services licenses to use this option.
Keep VIA window minimized	Enable this option to minimize the VIA client to system tray during the connection phase. Applicable to VIA client installed in computers running Microsoft Windows operating system.
Block traffic until VPN tunnel is up	If enabled, this feature will block network access until the VIA VPN connection is established.
Block traffic rules	Specify a hostname or IP address and network mask to define a whitelist/allowlist of users to which the Block traffic until VPN tunnel is up setting will not apply.

show aaa authentication via global-config

show aaa authentication via global-config

Description

This command shows the VIA global configuration.

Example

The following example shows the VIA global configuration:

```
(host) [mynode] #show aaa authentication via global-config

VIA Global Configuration
-----
Parameter                               Value
-----
Allow VIA SSL Fallback                   Enabled
Max Concurrent VIA VPN Sessions per user 5
```

Related Commands

Command	Description
aaa authentication via global-config	This command allows you to enable SSL fallback mode.

Command History

Release	Modification
ArubaOS 8.11.0.0	The command output displays the maximum number of concurrent VIA VPN sessions allowed per user.
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Enable mode on Mobility Conductor or managed devices.

show aaa authentication via web-auth

```
show aaa authentication via web-auth [default]
```

Description

A VIA web authentication profile contains an ordered list of VIA authentication profiles. The web authentication profile is used by end users to login to the VIA download page (<https://<server-IP-address>/via>) for downloading the VIA client. Only one VIA web authentication profile is available. If more than one VIA authentication profile is configured, users can view this list and select one during the client login.

Issue this command to view the authentication profiles associated with the default web authentication profile. Use it without the profile name to see the list of authentication profiles.

Examples

```
(host) #show aaa authentication via web-auth

VIA Web Authentication List
-----
Name       References  Profile Status
----       -
default    2

Total:1

(host) #show aaa authentication via web-auth default

VIA Web Authentication "default"
-----
Parameter                               Value
-----
VIA Authentication Profiles             vial
```

The output of this command includes the following parameters:

Parameter	Description
VIA Authentication Profiles	This is the name of the VIA authentication profile. The value column displays the order of priority in which the profiles are displayed in the VIA client login.

Related Commands

Command	Description
aaa authentication via web-auth	The web authentication profile is used by end users to login to the VIA download page (<i>https://<server-IP-address>/via</i>) for downloading the VIA client.

show aaa authentication vpn

```
show aaa authentication vpn [default|default-cap|default-rap]
```

Description

This command displays VPN authentication settings, including authentication roles and servers. Issue this command to identify the default role assigned to VPN users, the name of the group of servers used to authenticate the VPN users, and the maximum number of authentication failures allowed before the user is blacklisted/denylisted.

Example

The following example displays configuration details for the VPN authentication profile **default**, **default-cap** and **default-rap**.

```
(host) #show aaa authentication vpn default

VPN Authentication Profile "default"
-----
Parameter                               Value
-----
Default Role                             default-vpn-role
Server Group                             default
RADIUS Accounting Server Group           N/A
Max Authentication failures               0
Check certificate common name against AAA server Enabled
Export VPN IP address as a route         Enabled
User idle timeout                         N/A
PAN Firewall Integration                  Disabled

(TechPubs) #show aaa authentication vpn default-cap

VPN Authentication Profile "default-cap" (Predefined (changed))
-----
Parameter                               Value
-----
Default Role                             sys-ap-role
Server Group                             internal
RADIUS Accounting Server Group           N/A
Max Authentication failures               0
Check certificate common name against AAA server Enabled
Export VPN IP address as a route         Enabled
User idle timeout                         N/A
PAN Firewall Integration                  Disabled

(TechPubs) #show aaa authentication vpn default-rap

VPN Authentication Profile "default-rap" (Predefined (changed))
-----
Parameter                               Value
```

```

-----
Default Role                               default-vpn-role
Server Group                               default
RADIUS Accounting Server Group            N/A
Max Authentication failures                0
Check certificate common name against AAA server Enabled
Export VPN IP address as a route          Enabled
User idle timeout                          N/A
PAN Firewall Integration                   Disabled

```

Parameter	Description
Default Role	The default role to be assigned to VPN users.
Server Group	The name of the server group that performs the authentication.
RADIUS Accounting Server Group	The name of the RADIUS accounting server group.
Max Authentication failures	Number of times a user attempted to authenticate, but failed.
Check certificate common name against AAA server	When enabled, this parameter triggers a validation against the configured AAA server.
Export VPN IP address as a route	When enabled, any VPN client address is exported to OSPF using IPC.
User idle timeout	The amount of time in minutes that a user can be inactive before the user's session times out and closes.
PAN Firewall Integration	Integration with existing Palo Alto Networks (PAN) firewalls policy.

show aaa authentication wired

```
show aaa authentication wired
```

Description

View wired authentication settings for a client device that is directly connected to a port on the controller. This command displays the name of the AAA profile currently used for wired authentication.

Example

The following example shows the current wired profile for the controller is a profile named default.

```
(host) #show aaa authentication wired
Wired Authentication Profile
-----
Parameter      Value
-----
AAA Profile    default
Denylist-time  3600 sec
```

show aaa authentication wispr

```
show aaa authentication wispr <profile-name>
```

Description

This command shows information for a WISPr authentication profiles. Issue this command without the **<profile-name>** option to display the entire WISPr Authentication profile list, including profile status and the number of references to each profile. Include a profile name to display detailed WISPr authentication configuration information for that profile.

Parameter	Description
<profile-name>	The name of an existing MAC authentication profile.

Examples

The output of the example below shows two WISPr authentication profiles, **default** and **WISPr1**, which are referenced two times by other profiles. the **Profile Status** columns are blank, indicating that these profiles are both user-defined. (If a profile is predefined, the value **Predefined** appears in the Profile Status column.)

```
(host) #show aaa authentication wispr

WISPr Authentication Profile List
-----
Name           References  Profile Status
-----
default        2
WISPr1 2
Total:2
```

The following example displays configuration details for the WISPr authentication profile "default".

```
(host) ##show aaa authentication wispr default

WISPr Authentication Profile "default"
-----
Parameter                               Value
-----
Default Role                             guest
Server Group                             default
Max Authentication failures              0
```

```

User Agent String          N/A
Logon wait minimum wait   5 sec
Logon wait maximum wait   10 sec
logon wait CPU utilization threshold 60 %
WISPr Location-ID ISO Country Code N/A
WISPr Location-ID E.164 Country Code N/A
WISPr Location-ID E.164 Area Code N/A
WISPr Location-ID SSID/Zone N/A
WISPr Operator Name       N/A
WISPr Location Name       N/A

```

The output of this command includes the following parameters:

Parameter	Description
Default Role	The default role assigned to users that have completed WISPr authentication.
Server Group	The name of the server group that performs the authentication.
Max Authentication failures	Displays the number of maximum auth failures before user is denylisted.
User Agent String	Displays the user agent string registered for use in WISPR Profile.
Logon wait minimum wait	If the controller's CPU utilization has surpassed the Logon wait CPU utilization threshold value , the <code>Logon wait minimum wait</code> parameter defines the minimum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 5 seconds.
Logon wait maximum wait	If the controller's CPU utilization has surpassed the logon wait CPU utilization threshold value , the <code>Logon wait maximum wait</code> parameter defines the maximum number of seconds a user will have to wait to retry a login attempt. Range: 1-10 seconds. Default: 10 seconds.
WISPr Location-ID E.164 Area Code	The E.164 Area Code in the WISPr Location ID.
WISPr Location-ID E.164 Country Code 1	The 1-3 digit E.164 Country Code in the WISPr Location ID.

Parameter	Description
WISPr Location-ID ISO Country Code	The ISO Country Code in the WISPr Location ID.
WISPr Location-ID SSID/Zone	The SSID/network name in the WISPr Location ID.
WISPr Location Name	A name identifying the hotspot location. If no name is defined, the default ap-name is used.
WISPr Operator Name	A name identifying the hotspot operator.

Related Commands

show aaa authentication-server all

```
show aaa authentication-server all
```

Description

View authentication server settings for both external authentication servers and the internal controller database. The output of this command displays statistics for the Authentication Server Table, including the name and address of each server, server type and configured authorization and accounting ports.

Example

The following command shows information for the internal Authentication server, and another RADIUS server named RADIUS-1.

```
(host) #show aaa authentication-server all

Auth Server Table
-----
Name   Type  FQDN  IP addr  AuthPort  AcctPort  Status  Requests
-----
Internal Local n/a  10.4.62.11 n/a   n/a   Enabled  0
server  Ldap  n/a  0.0.0.0  389   n/a   Enabled  0
server  Radius SRVR1 127.9.9.61 1812  1813  Enabled  0
default Tacacs n/a  127.9.10.61 49    n/a   Enabled  0
```

The following data columns appear in the output of this command:

Parameter	Description
Name	Name of the authentication server.
Type	The type of authentication server. ArubaOS supports LDAP, RADIUS and TACACS+ servers, in addition to its own local, internal authentication server.
FQDN	The Fully-Qualified Domain Name of the server, if configured.
IP addr	IP address of the server, in dotted-decimal format.
AuthPort	Port number used for authentication. An LDAP server uses port 636 for LDAP over SSL, and port 389 for SSL over LDAP, Start TLS operation and clear text. The default RADIUS authentication port is port 1812.

Parameter	Description
AcctPort	Accounting port on the server. The default RADIUS accounting port is port 1813.
AcctPort	Accounting port on the server.
Status	Shows whether the Authentication server is enable or disabled.
Requests	Number of authentication requests received by the server.

Related Commands

Command	Description
aaa authentication-server internal	This command specifies that the internal database on a managed device be used for authenticating clients.

All platforms	Base operating system.	Enable and Config mode on Mobility Conductor.

show aaa authentication-server internal

```
show aaa authentication-server internal [statistics]
```

Description

View authentication server settings for the internal controller database.

Examples

The output of the command below shows that the internal authentication server has been disabled:

```
(host) #show aaa authentication-server internal

Internal Server
-----
Host   IP addr   Retries Timeout Status
-----
Internal 10.168.254.221 3    5    Disabled
```

The following data columns appear in the output of this command:

Parameter	Description
Host	Name of the internal authentication server.
IP addr	Address of the internal server, in dotted-decimal format.
Retries	Number of retries allowed before the server stops attempting to authenticate a request.
Timeout	Timeout period, in seconds.
Status	Shows if the server is enabled or disabled

Include the `statistics` parameter to display additional details for the internal server.

```
(host) #show aaa authentication-server internal statistics

Internal Database Server Statistics
-----
PAP Requests           8
PAP Accepts            8
PAP Rejects            0
MSCHAPv2 Requests     0
MSCHAPv2 Accepts      0
```

```

MSCHAPv2 Rejects      0
Mismatch Response     0
Users Expired         1
Unknown Response      0
Timeouts              1
AvgRespTime (ms)     0
Uptime (d:h:m)       4:3:32
SEQ first/last/free  1,255,255

```

The following data columns appear in the output of this command:

Parameter	Description
PAP Requests	Number of PAP requests received by the internal server.
PAP Accepts	Number of PAP requests accepted by the internal server.
PAP Rejects	Number of PAP requests rejected by the internal server.
MSCHAPv2 Requests	Number of MSCHAPv2 requests received by the internal server.
MSCHAPv2 Accepts	Number of MSCHAPv2 requests accepted by the internal server.
MSCHAPv2 Rejects	Number of MSCHAPv2 requests rejected by the internal server.
Mismatch Response	Number of times the server received an authentication response to a request after another request had been sent.
Users Expired	Number of users that were deauthenticated because they stopped responding.
Unknown Response	Number of times the server did not recognize the response, possibly due to internal errors.
Timeouts	Number of times that the controller timed out an authentication request.
AvgRespTime (ms)	Time it takes the server to respond to an authentication request, in seconds.
Uptime (d:h:m)	Time elapsed since the last server reboot.
SEQ first/last/free	This internal buffer counter keeps track of the requests to the authentication server.

Related Commands

Command	Description

show aaa authentication-server ldap

```
show aaa authentication-server ldap [statistics|<ldap_server_name> status]
```

Description

This command shows the configuration settings of LDAP servers.

Parameter	Description
statistics	Shows the statistics of all LDAP servers.
<ldap_server_name> status	Shows the status of the specified LDAP server.

Examples

The following example shows the LDAP server list with the names of all the LDAP servers:

```
(host) [mynode] #show aaa authentication-server ldap

LDAP Server List
-----
Name   References  Profile Status
----  -
ldap1  5
ldap2  3
ldap3  1

Total:3
```

The **References** column lists the number of other profiles that reference an LDAP server, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

Related Commands

show aaa authentication-server radius

```
show aaa authentication-server radius [statistics|<rad_server_name> radsec status]
```

Description

This command shows the configuration settings of RADIUS servers.

Parameter	Description
statistics	Shows the statistics of all RADIUS servers.
<rad_server_name> radsec status	Shows status of RADIUS over TLS of specified RADIUS server.

Examples

The following example shows the RADIUS server list with the names of all the RADIUS servers:

```
(host) [mynode] #show aaa authentication-server radius

RADIUS Server List
-----
Name           References  Profile Status
----           -
myserver       3
radius         0
servername     0

Total:3
```

The **References** column lists the number of other profiles that reference a RADIUS server, and the **Profile Status** column indicates whether the profile is predefined. User-defined servers will not have an entry in the **Profile Status** column.

Include the optional `statistics` parameter to this command to show the following statistics for all RADIUS servers:

Parameter	Description
Server	Name of the RADIUS server.
Acct Rq	Accounting requests. This reports of the number of accounting messages (for example, start/stop/interim update) sent by the controller to a RADIUS server. This counter increments whenever the controller sends one of these messages.

Parameter	Description
Raw Rq	Raw requests. Number of raw authentication requests the controller sent to a RADIUS server.
PAP Rq	Pap Requests. Number of PAP authentication requests the controller sent to a RADIUS server.
CHAP Rq	CHAP requests. Number of CHAP authentication requests the controller sent to a RADIUS server.
MSCHAP Rq	MSCHAP requests. Number of MS-CHAP authentication requests the controller sent to a RADIUS server.
MSCHAPv2 Rq	MSCHAPv2 requests. Number of MS-CHAPv2 requests the controller sent to a RADIUS server.
Mismatch Rsp	Mismatch responses. Number of responses from a RADIUS server for which the controller does not have the proper request context.
Bad Auth	Bad authenticator. Number of responses from the RADIUS server with an invalid secret or bad reply digest.
Acc	Access accept. Number of responses from the RADIUS server that indicate that client authentication succeeded.
Rej	Access reject. Number of responses from the RADIUS server that indicate that client authentication failed.
Acct Rsp	Accounting response. Number of responses sent from the RADIUS server in response to accounting requests sent from the controller.
Chal	Access challenge. Number of responses from the RADIUS server containing a challenge for the client (to complete authentication).
Ukn Rsp	Unknown Response code. Number of responses from the RADIUS server that were not understood by the controller due to the purpose or type of the response
Tmout	Timeouts. Number of messages sent by the controller for which the controller did not receive a response before the message timed out. NOTE: Timeouts include RADIUS accounting requests. Every request controller sends to the RADIUS server is monitored for a timeout, so each retry increments this counter.
AvgRspTme	Average response time. Time taken, on an average, for the RADIUS server to respond to a message from the controller.

Parameter	Description
Tot Rq	Total errors. This counter reflects the total number of requests sent to the RADIUS server (auth and accounting requests).
Tot Rsp	This counter reflects the total number of responses received by the RADIUS server (auth and accounting responses).
Rd Err	Read errors. This counter reflects the total number of errors encountered while reading off socket corresponding to that RADIUS server.
Uptime	Amount of for which the RADIUS server has been active/up. The RADIUS server is considered to have an UP status if the server is active and serving requests. The RADIUS server is considered to be DOWN if the server is not responding. For example, if the RADIUS server does not respond for (<no of retries> * < timeout>) seconds, the controller takes the RADIUS server down. It brings the radius server back into service after the dead timeout.
SEQ	Information corresponding to the sequence number of requests. SEQ total corresponds to the total number of sequence numbers that can be used to communicate with the RADIUS server. SEQ free corresponds to the free/available/not in use sequence numbers for a particular RADIUS server.

The following example shows additional details for a RADIUS server named alpha:

```
(host) [mynode] #show aaa authentication-server radius alpha

RADIUS Server "alpha"
-----
Parameter                               Value
-----
Host                                     10.15.28.101
Key                                     *****
CPPM credentials                         ade/*****
Auth Port                               1812
Acct Port                               1813
Radsec Port                             2083
Retransmits                             3
Timeout                                 5 sec
NAS ID                                  N/A
NAS IP                                   N/A
Enable IPv6                             Disabled
NAS IPv6                                 N/A
Source Interface                         N/A
Use MD5                                  Disabled
Use IP address for calling station ID    Disabled
Mode                                     Enabled
Lowercase MAC addresses                  Disabled
MAC address delimiter                    none
```

```

Service-type of FRAMED-USER      Disabled
Radsec                           Enabled
Radsec Trusted CA Name          can-new
Radsec Server Cert Name         N/A
Radsec Client Cert              client-new
called-station-id               macaddr colon disable

```

The output of this command includes the following information:

Parameter	Description
Host	IP address of the RADIUS server
Key	Shared secret between the controller and the authentication server.
CPPM credentials	Setting this parameter allows the controller to use configurable username and password instead of a support password.
Auth port	Authentication port on the server.
Acct Port	Accounting port on the server.
Radsec Port	Displays the Radsec port for RADIUS data transport.
Retransmits	Maximum number of retries sent to the server by the controller before the server is marked as down.
Timeout	Maximum time, in seconds, that the controller waits before timing out the request and resending it.
NAS ID	Network Access Server (NAS) identifier to use in RADIUS packets.
NAS IP	NAS IP address to send in RADIUS packets. If you do not configure a server-specific NAS IP, the global NAS IP is used.
Enable IPv6	Shows if the RADIUS server is enabled in IPv6 mode.
NAS IPv6	IPv6 address for the global NAS IP which the controller uses to communicate with all the RADIUS servers.
Source Interface	The source interface VLAN ID number.

Parameter	Description
Use MD5	If enabled, the RADIUS server will use a MD5 hash of cleartext password.
Use IP address for calling station ID	If enabled, the RADIUS server will use an IP address instead of a MAC address for calling station IDs.
Mode	Shows whether this server is Enabled or Disabled .
Lowercase MAC addresses	If this feature is enabled, the server will send MAC addresses in lowercase letters.
MAC address delimiter	The character used as a MAC address delimiter. If no character is specified, the RADIUS server will use a colon (:) by default.
Service-type of FRAMED-USER	If this option is enabled, the server sends the service-type as FRAMED-USER instead of LOGIN-USER. This option is disabled by default
Radsec	Displays the status of the Radsec server.
Radsec Trusted CA	Displays the Certificate Authority to sign Radsec certificates.
Radsec Server Cert Name	Displays the trusted Radsec server certificate.
Radsec Client Cert	Displays the Radsec client certificate on the RADIUS server that identifies and authenticates clients.
called-station-id	Configure this parameter to be sent with the RADIUS attribute Called Station ID for authentication and accounting requests. The <code>called-station-id</code> parameter can be configured to include AP group, AP MAC address, AP name, controller IP, controller MAC address, or user vlan. The default value is controller MAC address.

The following example shows details of RADIUS over TLS for a RADIUS server named beta:

```
(host) [mynode] #show aaa authentication-server radius <servername> radsec
status

Radius Server "beta" Radsec Status
-----
Radsec Server Attribute  Value
-----
In Service                Yes
```

Connected Sockets

1

The output of this command includes the following information:

Parameter	Description
In Service	Shows the status of the Radsec RADIUS server.
Connected Sockets	Shows the number of TLS connections with the RADIUS server.

Related Commands

show aaa authentication-server tacacs

```
show aaa authentication-server tacacs [<tacacs_server_name>]|statistics
```

Description

Display configuration settings for your TACACS+ servers.

Parameter	Description
<tacacs_server_name>	Name that identifies an TACACS+ server.
statistics	Displays accounting, authorization, and authentication request and response statistics for the TACACS server.

Examples

The output of the example below displays the TACACS+ server list with the names of all the TACACS+ servers. The **References** column lists the number of other profiles that reference a TACACS+ server, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #aaa authentication-server tacacs

TACACS Server List
-----
Name                References  Profile Status
-----
LabAuth              5
TACACS1              3

Total:2
```

Include the <tacacs_server_name> parameter to display additional details for an individual server.

```
(host) #show aaa authentication-server tacacs tacacs1

TACACS Server "tacacs1"
-----
Parameter    Value
-----
Host          10.1.1.16
Key           *****
TCP Port      49
Retransmits   3
Timeout       20 sec
```

Mode Enabled

The output of this command includes the following parameters:

Parameter	Description
host	IP address of the TACACS+ server
Key	Shared secret between the controller and the authentication server.
TCP Port	TCP port used by the server.
Retransmits	Maximum number of retries sent to the server by the controller before the server is marked as down.
Timeout	Maximum time, in seconds, that the controller waits before timing out the request and resending it.
Mode	Shows whether this server is Enabled or Disabled .

show aaa authentication-server windows

```
show aaa authentication-server windows [<windows_server_name>]
```

Description

Display configuration settings for your Windows servers.

Parameter	Description
<windows_server_name>	Name that identifies a Windows server.

Examples

The output of the example below displays the Windows server list with the names of all the Windows servers used for NTLM authentication. The **References** column lists the number of other profiles that reference a Windows server, and the **Profile Status** column indicates whether the profile is predefined. User-defined profiles will not have an entry in the **Profile Status** column.

```
(host) #aaa authentication-server windows

Windows Server List
-----
Name                References  Profile Status
----                -
NTLM                 1
Windows2            1

Total:2
```

Include the <windows_server_name> parameter to display additional details for an individual server.

```
(host) #show aaa authentication-server windows Windows2

Windows Server "windows"
-----
Parameter          Value
-----
Host                172.21.18.170
Mode                Enabled
Windows Domain     MyCompanyDomain
```

The output of this command includes the following parameters:

Parameter	Description
host	IP address of the Windows server
Mode	Shows whether this server is Enabled or Disabled .
Windows Domain	Name of the Windows domain to which this server is assigned.

Related Commands

Command	Description

show aaa bandwidth-contracts

```
show aaa bandwidth-contracts [dynamic | name]
```

Description

This command shows the contract names, ID numbers, Rate limits, and Note for your bandwidth contracts.

Parameter	Description
dynamic	Displays dynamic bandwidth contracts.
name	Displays the bandwidth contract for the name specified.

Example

Specify a bandwidth contract name to view information for a specific bandwidth contract, or omit that parameter to view information for all bandwidth contracts configured . The output of the following command shows that the bandwidth contract **VLAN** has a configured rate of 6 Mbps, and the contract **User** has a rate of 2048 Kbps.

```
(host) #show aaa bandwidth-contracts VLAN

Bandwidth Contract
-----
Contract      Id  Rate (bits/second)
-----
VLAN          1   6000000
User          2   2048000

Total contracts = 2
Per-user contract total = 4096
Per-user contract usage = 0
```

Execute the following command to view the dynamic bandwidth contracts:

```
(host) #show aaa bandwidth-contracts dynamic

Dynamic Bandwidth Contracts
-----
Contract                                     Id  Rate           Note
-----
"$#-DBW-0000000004-UP"                       3   2000000 bps   Group(1)
"$#-DBW-0000000004-DN"                       4   1000000 bps   Group(1)
"$#-DBW-44:00:00:00:00:02-UP"                 5   5000000 bps   Individual
"$#-DBW-44:00:00:00:00:02-DN"                 6   6000000 bps   Individual
"$#-DBW-44:00:00:00:00:03-UP"                 7   5000000 bps   Individual
```

```
"$#-DBW-44:00:00:00:00:03-DN" 8 6000000 bps Individual
Total Instances: 6
```

show aaa cluster essid

```
show aaa cluster essid <ssid_val>
```

bucketmap	all buckets in cluster essid table
counters	display bucket counters
keycache	keycache
mac	Match macaddr
users	all users

Description

This command displays information on essid counters, bucketmap, dormant keycache, mac address, and dormant user entries for a particular ESSID.

Parameter	Description
bucketmap	Displays the bucketmap details for a specified bucket.
counters	Displays all the bucket counters.
keycache [standby]	Displays the dormant keycache entries.
users [standby]	Displays all user entries in dormant hash table.
mac	Displays the match mac address

Example

The output of the example below displays the bucketmap details and the counters for the essid, Zone1TestEssid:

```
show aaa cluster essid Zone1TestEssid bucketmap bucket 2
```

```
(host) (config) #show aaa cluster essid Zone1TestEssid bucketmap bucket 2

Active Bucket Values
-----
Essid      Bucket  ActiveUAC   StandbyUAC   L2Conn  IS_Active  IS_

show aaa debug

```
show aaa debug
  age {dev-id-cache [mac <A:B:C:D:E:F>]|key-cache [mac <A:B:C:D:E:F>]|pmk-cache
    [mac <A:B:C:D:E:F>]}
  dev-id-cache
  pmk bss-table [<A:B:C:D:E:F>]
  role user {ip <A.B.C.D>|ipv6 <ipv6addr>|mac <A:B:C:D:E:F>}
  stm
  vlan user {ip <A.B.C.D>|ipv6 <ipv6addr>|mac <A:B:C:D:E:F>}
```

Description

This command shows AAA related debug information.

Parameter	Description
age dev-id-cache key-cache pmk-cache	Displays the age of the GSM entry since the previous refresh (in seconds) based on: <ul style="list-style-type: none">▪ dev-id-cache—Device ID information in memory.▪ key-cache—Key cache information in memory.▪ pmk-cache—Pairwise Master Key (PMK) cache information in memory.
dev-id-cache section mac <mac address>	Displays Device Id cache section CPPM information in memory.
pmk bss-table	Displays PMK related debug information based on the BSSID address.
role user ip ipv6 mac	Displays role derivation related debug information based on: <ul style="list-style-type: none">▪ ip—IPv4 address of the client.▪ ipv6—IPv6 address of the client.▪ mac—MAC address of the client.
stm message stats	Displays information about number of messages sent or received from stm.
vlan user ip ipv6 mac	Displays VLAN derivation related debug information based on: <ul style="list-style-type: none">▪ ip—IPv4 address of the client.▪ ipv6—IPv6 address of the client.▪ mac—MAC address of the client.

Example

The following example shows the VLAN derivation debug information of an user with IPv4 address.

```
(host) [mynode] #show aaa debug vlan user ip 192.0.2.1

VLAN types present for this User
=====
Default VLAN                : 3
Initial Role Contained      : 1
User Dot1x Role Contained   : 5
Dot1x Server Rule           : 5

VLAN Derivation History
=====
VLAN Derivation History Index : 8
1. VLAN 1    for Default VLAN
2. VLAN 1    for Current VLAN updated
3. VLAN 0    for Reset VLANs for Station up
4. VLAN 3    for Default VLAN
5. VLAN 1    for Initial Role Contained
6. VLAN 5    for Dot1x Server Rule
7. VLAN 5    for User Dot1x Role Contained
8. VLAN 5    for Current VLAN updated

Current VLAN : 5 (Dot1x Server Rule)
```

show aaa debug pmk bss-table

```
show aaa debug pmk bss-table [bssid <bssid>]
```

Description

This command shows information linking the PMK to the BSS.

Parameter	Description
bssid <bssid>	Shows information linking the PMK to the specified BSSID.

Example

The following example shows the authentication survivability cached data:

```
(host) [mynode] #show aaa debug pmk bss-table

PMK BSS-Table
-----
BSSID  Mac Address
-----

Total entries = 0
```

show aaa debug vlan user

```
show aaa debug vlan user [ip <ip addr>|ipv6 <ipv6addr>|mac <macaddr>]
```

Description

Displays user VLAN derivation related debug information.

Parameter	Description
ip <ip addr>	User identification based on IPv4 address.
ipv6 <ipv6addr>	User identification based on IPv6 address.
mac <macaddr>	User identification based on MAC address.

Example

The output of the example below displays the VLAN derivation debug information of a user with IPv4 address.

```
(host) #show aaa debug vlan user ip 192.0.2.1

VLAN types present for this User
=====
Default VLAN                : 3
Initial Role Contained      : 1
User Dot1x Role Contained   : 5
Dot1x Server Rule           : 5

VLAN Derivation History
=====
VLAN Derivation History Index : 8
1. VLAN 1    for Default VLAN
2. VLAN 1    for Current VLAN updated
3. VLAN 0    for Reset VLANs for Station up
4. VLAN 3    for Default VLAN
5. VLAN 1    for Initial Role Contained
6. VLAN 5    for Dot1x Server Rule
7. VLAN 5    for User Dot1x Role Contained
8. VLAN 5    for Current VLAN updated

Current VLAN : 5 (Dot1x Server Rule)
```

show aaa derivation-rules

```
show aaa derivation-rules [server-group <group-name>|user <name>]
```

Description

Show derivation rules based on user information or configured for server groups.

Parameter	Description
<group-name>	Name of a server group
<name>	Name of a user rule group

Example

The output of the following command shows that the server group group1 has the internal database configured as its authentication server, and that there is a single rule assigned to that group. You can omit the <group-name> parameter to show a table of all your server groups.

```
(host) #show aaa derivation-rules server-group group1

Server Group

Name          Inservice  trim-FQDN  match-FQDN
----          -
Internal      Yes        No

Server Rule Table
-----
Priority  Attribute  Operation  Operand  Action  Value  Total Hits  New
Hits
-----  -
1        Filter-Id  equals     nsFilter  set vlan  111    24
                                0

Rule Entries: 1
```

The following data columns appear in the output of this command:

Parameter	Description
Name	Name of the authentication server assigned to this server group
Inservice	Specifies if the server is in service or out-of-service.

Parameter	Description
trim-FDQN	If enabled, user information in an authentication request is edited before the request is sent to the server.
match-FDQN	If enabled, the authentication server is associated with a specified domain.
Priority	The priority in which the rules are applied. Rules at the top of the list are applied before rules at the bottom.
Attribute	This is the attribute returned by the authentication server that is examined for Operation and Operand match
Operation	<p>This is the match method by which the string in Operand is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> ■ contains – The rule is applied if and only if the attribute value contains the string in parameter Operand. ■ starts-with – The rule is applied if and only if the attribute value returned starts with the string in parameter Operand. ■ ends-with – The rule is applied if and only if the attribute value returned ends with the string in parameter Operand. ■ equals – The rule is applied if and only if the attribute value returned equals the string in parameter Operand. ■ not-equals – The rule is applied if and only if the attribute value returned is not equal to the string in parameter Operand. ■ value-of – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied.
Operand	This is the string to which the value of the returned attribute is matched.
Action	This parameter identifies whether the rule sets a server group role (set role) or a VLAN (set vlan).
Value	Sets the user role or VLAN ID to be assigned to the client if the condition is met.
Total Hits	Number of times the rule has been applied since the last server reboot.
New Hits	Number of times the rule has been applied since the show aaa derivation-rules command was last issued.

To display derivation rules for a user group, include the `user <name>` parameter. You can also display a table of all user rules by including the `user` parameter, but omitting the `<name>` parameter

```
(host) #show aaa derivation-rules user user44
User Rule Table
-----
Priority  Attribute  Operation  Operand  Action    Value  Total Hits  New
Hits      Description
-----
--
1         location  equals    ap23     18        set role  guest  56
```

The following data columns appear in the output of this command:

Parameter	Description
Priority	The priority in which the rules are applied. Rules at the top of the list are applied before rules at the bottom.
Attribute	This is the attribute returned by the authentication server that is examined for Operation and Operand match.
Operation	This is the match method by which the string in Operand is matched with the attribute value returned by the authentication server. <ul style="list-style-type: none"> ■ contains – The rule is applied if and only if the attribute value contains the string in parameter Operand. ■ starts-with – The rule is applied if and only if the attribute value returned starts with the string in parameter Operand. ■ ends-with – The rule is applied if and only if the attribute value returned ends with the string in parameter Operand. ■ equals – The rule is applied if and only if the attribute value returned equals the string in parameter Operand. ■ not-equals – The rule is applied if and only if the attribute value returned is not equal to the string in parameter Operand. ■ value-of – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied.
Operand	This is the string to which the value of the returned attribute is matched.
Action	This parameter identifies whether the rule sets a server group role (set role) or a VLAN (set vlan).

Parameter	Description
Value	Sets the user role or VLAN ID to be assigned to the client if the condition is met.
Total Hits	Number of times the rule has been applied since the last server reboot.
New Hits	Number of times the rule has been applied since the show aaa derivation-rules command was last issued.
Description	This optional parameter describes the rule. If no description was configured then it does not appear when you view the User Table.

Related Commands

Command	Description
aaa derivation-rules	This command configures rules which assigns a AAA profile, user role or VLAN to a client based upon the client's association with an AP.

show aaa device-id-cache

```
show aaa device-id-cache [mac <A:B:C:D:E:F>] [rows number number]
```

Description

This command shows the device ID cache information.

Parameter	Description
mac <A:B:C:D:E:F>	Shows device ID cache information for specified MAC address.
rows number number	Shows device ID cache information for specified rows starting at specified row number.

Example

The following example shows the device ID cache information:

```
(host) [mynode]# show aaa device-id-cache

Device ID Cache
-----
MAC   Device ID   Last Update
---   -
Device ID Cache Entries : 0
```

show aaa dns-query-interval

```
show aaa dns-query-interval <minutes>
```

Description

View the configured interval between DNS requests sent from the controller to the DNS server. If you define a RADIUS server using the FQDN of the server rather than its IP address, the controller will periodically generate a DNS request and cache the IP address returned in the DNS response. By default, DNS requests are sent every 15 minute, but the interval can be changed using the `aaa dns-query-period` command. Issue the `show aaa dns-query-period` command to view the current DNS query interval.

Example

This command shows that the controller will send a DNS query every 30 minutes

```
(host) # show aaa dns-query-period
DNS Query Interval = 30 minutes
```

Related Commands

Command	Description
aaa dns-query-interval	This command configures the DNS query interval.

show aaa fqdn-server-names

```
show aaa fqdn-server-names
```

Description

Show a table of IP addresses that have been mapped to fully qualified domain names (FQDNs). If you define a RADIUS server using the FQDN of the server rather than its IP address, the controller will periodically generate a DNS request and cache the IP address returned in the DNS response. Issue this command to view the IP address that currently correlates to each RADIUS server FQDN.

Example

The output of this command shows the IP addresses for two RADIUS servers.

```
(host) #show aaa fqdn-server-names

Auth Server FQDN names
-----
FQDN                IP Address      IPv6 Address    Refcount
----                -
myhost1.example.com 192.0.2.3
2myhost2.example.com 192.0.2.5      3
```

show aaa load-balance statistics

show aaa load-balance statistics server-group <sg_name>

Description

Displays the load balancing statistics for RADIUS servers.

Parameter	Description
<sg_name>	Name of the server group.

Example

```
(host) #show aaa load-balance statistics server-group dot1x-test-apsim
Statistics for Radius Servers in Server Group
-----
Server          Acct Rq  Raw Rq  PAP Rq  CHAP Rq  MSCHAP Rq  MSCHAPv2 Rq
Mismatch Rsp  Bad Auth  Acc  Rej  Acct Rsp  Chal  Ukn Rsp  Tmout  Tot Rq
Tot Rsp  Rd Err  Outstanding Auths
-----
-----
abc _RADIUS    0      0      0      0      0      0      26      0
              0      26     0     0      0      0      0      26     26
0              0
AUTOMATIONRAD 0      0      0      0      0      0      207     0
              0      207    0     0      0      0      0      207    207
0              0
```

The output of this command includes the following parameters:

Parameter	Description
Server	Name of the RADIUS server.
Acct Rq	Accounting requests. This reports the number of accounting messages (for example, start/stop/interim update) sent by the controller to a RADIUS server. This counter increments whenever the controller sends one of these messages.
Raw Rq	Raw requests. Number of raw authentication requests the controller sent to a RADIUS server.
PAP Rq	PAP Requests. Number of PAP authentication requests the controller sent to a RADIUS server.

Parameter	Description
CHAP Rq	CHAP requests. Number of CHAP authentication requests the controller sent to a RADIUS server.
MSCHAP Rq	MSCHAP requests. Number of MS-CHAP authentication requests the controller sent to a RADIUS server.
MSCHAPv2 Rq	MSCHAPv2 requests. Number of MS-CHAPv2 requests the controller sent to a RADIUS server.
Mismatch Rsp	Mismatch responses. Number of responses from a RADIUS server for which the controller does not have the proper request context.
Bad Auth	Bad authenticator. Number of responses from the RADIUS server with an invalid secret or bad reply digest.
Acc	Access accept. Number of responses from the RADIUS server with invalid secret or bad reply digest.
Rej	Access reject. Number of responses from the RADIUS server that indicate that client authentication failed.
Acct Rsp	Accounting response. Number of responses sent from the RADIUS server in response to accounting requests sent from the controller.
Chal	Access challenge. Number of responses from the RADIUS server containing a challenge for the client (to complete authentication).
Ukn Rsp	Unknown Response code. Number of responses from the RADIUS server that were not understood by the controller due to the purpose or type of the response
Tmout	Timeouts. Number of messages sent by the controller for which the controller did not receive a response before the message timed out. NOTE: Timeouts include RADIUS accounting requests. Every request controller sends to the RADIUS server is monitored for a timeout, so each retry increments this counter.
AvgRspTme	Average response time. Time taken, on an average, for the RADIUS server to respond to a message from the controller.
Tot Rq	Total errors. This counter reflects the total number of requests sent to the RADIUS server (auth and accounting requests).
Tot Rsp	This counter reflects the total number of responses received by the RADIUS server (auth and accounting responses).

Parameter	Description
Rd Err	Read errors. This counter reflects the total number of errors encountered while reading off socket corresponding to that RADIUS server.
Uptime	Amount of for which the RADIUS server has been active/up. The RADIUS server is considered to have an UP status if the server is active and serving requests. The RADIUS server is considered to be DOWN if the server is not responding. For example, if the RADIUS server does not respond for (<no of retries> * < timeout>) seconds, the controller takes the RADIUS server down. It brings the radius server back into service after the dead timeout.
SEQ	Information corresponding to the sequence number of requests. SEQ total corresponds to the total number of sequence numbers that can be used to communicate with the RADIUS server. SEQ free corresponds to the free/available/not in use sequence numbers for a particular RADIUS server.
Outstanding Auths	This value keeps track of the number of clients that are currently getting authenticated against this authentication server, i.e. clients for which the controller has sent Access-Request but has not yet received Access-Accept or Access-Reject and also the Access-Request has not timed out completely.

Related Commands

show aaa main-profile

show aaa main-profile summary

Description

Displays a summary of all AAA profiles.

Example

The output of the `show aaa main-profile summary` command shows roles, server group settings, and wire-to-wireless-roaming statistics for each AAA profile.

```
(host) #show aaa main-profile summary

AAA Profile summary
-----
Name          role      mac-auth  dot1x-  rad-  XML-api  RFC3576  UDR-  ww-  enforce
devtype -dhcp
-----
aaa_dot1x    logon    macprof2  dot1x   RADIUS 10.3.1.15 10.3.15.2  Usr1  Disable
enabled     disabled
default     logon    macprof2  dot1x   RADIUS 10.3.1.15 10.3.15.2  Usr1  Disable
enabled     disabled
default     guest    macprof1  default RADIUS 10.3.1.15 10.3.15.2  Usr2  Disable
enabled     disabled
guest
```

The following data columns appear in the output of this command:

Parameter	Description
Name	Name of the AAA profile.
role	Role for unauthenticated users.
mac-auth	Name of the server group used for MAC authentication.
dot1x-auth	Name of the server group used for dot1x authentication.
rad-act	Name of the server group used for RADIUS authentication.
XML-api	IP address of a configured XML API server.

Parameter	Description
RFC3576	IP address of a RADIUS server that can send user disconnect, session timeout and change-of-authorization messages, as described in RFC 3576.
UDR-group	Name of the user derivation rule profile.
ww-roam	Shows if wired-to-wireless roaming is enabled or disabled.
devtype	Shows if the device identification feature is enabled or disabled. When devtype-classification parameter is enabled, the output of the show user and show user-table commands shows each client's device type, if that client device can be identified.
enforce-dhcp	When this option is enabled, clients must complete a DHCP exchange to obtain an IP address. Best practices are to enable this option when you use the <code>aaa derivation-rules</code> command to create a rule with the DHCP-Option rule type. This parameter is disabled by default.

show aaa multiple-server-accounting statistics server-group

show aaa multiple-server-accounting statistics server-group <sg_name>

Description

This command shows the multiple server accounting statistics for a server-group.

Parameter	Description
<sg_name>	Shows the multiple server accounting statistics for the specified server-group.

Example

The following example shows the multiple server accounting statistics for a server-group corp1:

```
(host) [mynode] #show aaa multiple-server-accounting statistics server-group corp1

Multiple Server Accounting Statistics for Radius Servers in Server Group
-----
Server  Acct Start Req  Acct Interim Req  Acct Stop Req
-----

Acct Start Resp  Acct Interim Resp  Acct Stop Resp  Unknown Resp
-----
```

show aaa password-policy mgmt

show aaa password-policy mgmt [statistics]

Description

Displays the current password policy for management users.

Parameter	Description
statistics	Include this optional parameter to show the numbers of failed login attempts and any lockout periods for management user accounts.

Examples

The output of the `show aaa password-policy mgmt` command below shows that the current password policy requires a management user to have a password with a minimum of 9 characters, including one numeric character and one special character

```
(host) #show aaa password-policy mgmt

Mgmt Password Policy
-----
Parameter Value
-----
Enable password policy          Yes
Minimum password length required      9
Minimum number of Upper Case characters    0
Minimum number of Lower Case characters    0
Minimum number of Digits              1
Minimum number of Special characters (!, @, #, $, %, ^, &, *, <, >, {, }, [, ], :, ., comma, |, +, ~, `) 1
Username or Reverse of username NOT in Password    No
Maximum Number of failed attempts in 3 minute window to lockout user    0
Time duration to lockout the user upon crossing the "lock-out" threshold    3
Maximum consecutive character repeats    0
```

The following data columns appear in the output of this command:

Parameter	Description
Enable password policy	Shows if the defined policy has been enabled

Parameter	Description
Minimum password length required	Minimum number of characters required for a management user password. The default setting is 6 characters.
Minimum number of Upper Case characters	The maximum number of uppercase letters required for a management user password. By default, there is no requirement for uppercase letters in a password, and the parameter has a default value of 0.
Minimum number of Lower Case characters	The maximum number of lowercase letters required for a management user password. By default, there is no requirement for lowercase letters in a password, and the parameter has a default value of 0.

Parameter	Description
Minimum number of Digits	Minimum number of numeric digits required in a management user password. By default, there is no requirement for digits in a password, and the parameter has a default value of 0.
Minimum number of Special characters	Minimum number of special characters required in a management user password. By default, there is no requirement for special characters in a password, and the parameter has a default value of 0.
Username or Reverse of username NOT in Password	If Yes , a management user's password cannot be the user's username or the username spelled backwards. If No , the password can be the username or username spelled backwards.

Parameter	Description
Maximum Number of failed attempts in 3 minute window to lockout user	Number of times a user can unsuccessfully attempt to log in to the controller before that user gets locked out for the time period specified by the lock-out threshold below. By default, the password lockout feature is disabled, and the default value of this parameter is 0 attempts.
Time duration to lockout the user upon crossing the "lock-out" threshold	Amount of time a management user will be "locked out" and prevented from logging into the controller after exceeding the maximum number of failed attempts setting show above. The default lockout time is 3 minutes.
Maximum consecutive character repeats	The maximum number of consecutive repeating characters allowed in a management user password.

Parameter	Description
	By default, there is no limitation on the numbers of character that can repeat within a password, and the parameter has a default value of 0 characters.

```
(host) #show aaa password-policy mgmt statistics

Management User Table
-----
USER      ROLE    FAILED_ATTEMPTS  STATUS
-----
admin14  root    1                Locked until 12/1/2009 22:28
```

Include the optional `statistics` parameter to show failed login statistics in the Management User table. The example below shows that a single failed login attempt locked out the root user **admin14**, and displays the time when that user can attempt to login to the controller again.

Related Commands

Command	Description

show aaa profile

```
show aaa profile <profile-name>
```

Description

Displays configuration details for an individual AAA profile.

Example

The output of the following command shows roles, servers and server group settings, and wire-to-wireless-roaming statistics for each AAA profile.

```
(host) #show aaa profile default

AAA Profile "default"
-----
Parameter                                     Value
-----
Initial role                                   logon
MAC Authentication Profile                     N/A
MAC Authentication Default Role               guest
MAC Authentication Server Group               default
802.1X Authentication Profile                 N/A
802.1X Authentication Default Role           guest
802.1X Authentication Server Group           N/A
Download Role from CPPM                       Disabled
Set username from dhcp option 12              Disabled
L2 Authentication Fail Through                Disabled
Multiple Server Accounting                    Disabled
User idle timeout                             N/A
Max IPv4 for wireless user                    2
RADIUS Accounting Server Group                N/A
RADIUS Roaming Accounting                     Disabled
RADIUS Interim Accounting                     Disabled
RADIUS Acct-Session-Id In Access-Request      Disabled
XML API server                                N/A
RFC 3576 server                               N/A
User derivation rules                          N/A
Wired to Wireless Roaming                     Enabled
Reauthenticate wired user on VLAN change      Disabled
Device Type Classification                     Enabled
Enforce DHCP                                  Disabled
PAN Firewall Integration                      Disabled
Open SSID radius accounting                   Disabled
Apply ageout mechanism on bridge mode wireless clients Disabled
Diffie-Hellman Groups Supported for EnhancedOpen 19
```

The following data columns appear in the output of this command:

Parameter	Description
Name	The name of the AAA profile.
Initial Role	Role for unauthenticated users.
MAC Authentication Profile	Name of the MAC authentication profile.
MAC Authentication Default Role	Configured role assigned to the user after MAC authentication.
MAC Authentication Server Group	Name of the server group used for MAC authentication.
8021.X Authentication Profile	Name of the 802.1X authentication profile.
8021.X Authentication Default Role	Configured role assigned to the user after 802.1X authentication.
8021.X Authentication Server Group	Name of the server group used for 802.1X authentication.
Download Role from CPPM	Status of role download from ClearPass Policy Manager. If enabled, the controller downloads the role from ClearPass Policy Manager if not defined.
Set username from dhcp option 12	If enabled, username is set from dhcp option 12 for non-802.1x users.
L2 Authentication Fail Through	To select the other authentication method if one fails.
Multiple Server Accounting	Status of multiple server accounting. If enabled, the controller sends RADIUS accounting to all servers in RADIUS accounting server group.
User idle timeout	The user idle timeout for this profile. Specify the idle timeout value for the client in seconds. A value of 0, deletes the user immediately after disassociation from the wireless network. Valid range is 30-15300 in multiples of 30 seconds.
Max IPv4 for wireless user	Maximum number of IPv4 addresses allowed for wireless user.
RADIUS Accounting Server Group	Name of the server group used for RADIUS authentication.

Parameter	Description
RADIUS Roaming Accounting	Displays if Roaming RADIUS accounting service is enabled / disabled, assists in tracking a client who roams to a different AP.
RADIUS Interim Accounting	By default, the RADIUS accounting feature sends only start and stop messages to the RADIUS accounting server. If RADIUS Interim Accounting is enabled, the controller can also send Interim-Update messages with current user statistics to the server at regular intervals.
RADIUS Acct-Session-Id In Access-Request	When enabled, Acct-Session-Id is included in RADIUS access-request.
XML API server	IP address of a configured XML API server.
RFC 3576 server	IP address of a RADIUS server that can send user disconnect, session timeout and change-of-authorization messages, as described in RFC 3576.
User derivation rules	User attribute profile from which the user role or VLAN is derived.
Wired to Wireless Roaming	Shows whether Wired to Wireless Roaming is Enabled or Disabled .
Reauthenticate wired user on VLAN change	When enabled, wired user is reauthenticated when changing VLANs.
SIP authentication role	For controllers with an installed PEFNG license, this parameter displays the configured role assigned to a session initiation protocol (SIP) client upon registration.
Device Type Classification	Shows if the device identification feature is enabled or disabled. When devtype-classification parameter is enabled, the output of the show user and show user-table commands shows each client's device type, if that client device can be identified.

Parameter	Description
Enforce DHCP	When this option is enabled, clients must complete a DHCP exchange to obtain an IP address. Best practices are to enable this option when you use the <code>aaa derivation-rules</code> command to create a rule with the DHCP-Option rule type. This parameter is disabled by default.
PAN firewall Integration	Displays the status of the PAN firewall integration.
Open SSID Radius Accounting	Displays the Open system SSID RADIUS accounting status.
Apply ageout mechanism on bridge mode wireless clients	Displays the status of ageout mechanism. When enabled, ageout mechanism is applied on bridge mode wireless clients.
Diffie-Hellman Groups Supported for EnhancedOpen	Value set for supported Diffie-Hellman groups for EnhancedOpen. The possible values are 19,20, or 21.

show aaa rfc-3576-server

```
show aaa rfc-3576-server
<server-ip>
statistics
udp-port
```

Description

Show configuration details for an RFC-3576 server, which is a RADIUS server that can send user disconnect, session timeout and change-of-authorization (CoA) messages, as described in RFC 3576.

Parameter	Description
<server-ip>	IP address of an RFC-3576 server.
statistics	View detailed connection and authentication information for all RFC 3575 servers.
udp-port	Show the configured RFC3576 server port. The default value is port 3799.

Example

This first example shows that there are two configured servers in the RFC 3567 Server List. The **References** column lists the number of other profiles with references to the RFC 3567 server, and the **Profile Status** column indicates whether the server is predefined. User-defined servers will not have an entry in the **Profile Status** column.

```
(host)#show aaa rfc-3567-server

RFC 3576 Server List
-----
Name           References  Profile Status
-----
10.2.14.6      2
```

To view details for a specific server, include the IP address of that server in the command.

```
(host) #show aaa rfc-3576-server 192.0.2.31
RFC 3576 Server "192.0.2.31"
-----
Parameter      Value
-----
Key             *****
```

To view information for all RFC 3576 servers, include the `statistics` parameter.

```
(host)#show aaa rfc-3576-server statistics

RADIUS RFC 3576 Statistics
-----
Statistics          10.1.2.3  10.1.2.34
-----
Disconnect Requests  13         3
Disconnect Accepts   12         3
Disconnect Rejects   1          0
No Secret            0          0
No Session ID        0          0
Bad Authenticator    0          0
Invalid Request      0          0
Packets Dropped      0          2
Unknown service      0          0
CoA Requests         1          0
CoA Accepts          1          0
CoA Rejects          0          0
No permission        0          0

Packets received from unknown clients: 0
Packets received with unknown request: 0
Total RFC3576 packets Received       : 0
```

The output of the `show aaa rfc-3576-server statistics` command includes the following parameters:

Parameter	Description
Disconnect Requests	Number of disconnect requests sent by the server.
Disconnect Accepts	Number of disconnect requests sent by the server that were accepted by the user.
Disconnect Rejects	Number of disconnect requests sent by the server that were rejected by the user.
No Secret	Number of authentication requests that did not contain a RADIUS secret.
No Session ID	Number of authentication requests that did not contain a session ID.
Bad Authenticator	Number of authentication requests that contained a missing or invalid authenticator field in the packet.
Invalid Request	Number of invalid requests.
Packets Dropped	Number of packets dropped.

Parameter	Description
Unknown service	Number of requests for an unknown service type.
CoA Requests	Number of requests for a Change of Authorization (CoA).
CoA Accepts	Number of times a CoA request was accepted.
CoA Rejects	Number of times a CoA request was rejected.
No permission	Number of requests for a service that has been defined, but has not been administratively enabled.

Related Commands

Command	Description

show aaa server-group

```
show aaa server-group [<group-name>|summary]
```

Description

Displays configuration details for your AAA server groups. Issue this command without the **<group-name>** or **summary** options to display the entire server group list, including profile status and the number of references to each profile. The **References** column lists the number of other profiles that reference a server group, and the **Profile Status** column indicates whether the server group is predefined. User-defined server groups will not have an entry in the Profile Status column.

Parameter	Description
<group-name>	The name of an existing AAA server group.

Examples

This first example shows that there are five configured server groups

```
(host) #show aaa server-group

Server Group List
-----
Name                References  Profile Status
-----
auth-profile-2      1
coltrane-server-group 1
default             25
group1              0
internal            0          Predefined

Total:5
```

To view additional statistics for all server groups, include the `summary` parameter.

```
(host) #show aaa server-group summary

Server Groups
-----
Name                Servers  Rules  hits  Out-of-service
-----
auth-profile-2      1        0     0
coltrane-server-group 1        0     0
default             1        0     0
group1              1        1     0
internal            1        1     0
```

The output of the `show aaa server-group summary` command includes the following parameters:

Parameter	Description
name	Name of an existing AAA server group.
Servers	Number of servers in the group.
Rules	Number of rules configured for the server group.
hits	Number of hits for the server's rules.
Out-of-Service	Indicates whether the server is active, or out of service. Active servers may not have an entry in the Out-of-Service column.

To display detailed authorization, role and vlan statistics for an individual server group, include the name of the group for which you want more information.

```
(host) #show aaa server-group summary group1

Fail Through:No

Auth Servers
-----
Name          Server-Type  trim-FQDN  Match-Type  Match-Op  Match-Str

company_eng
rad3          Radius      No
company_qa

Role/VLAN derivation rules
-----
Priority  Attribute  Operation  Operand  Action  Value
-----
1         class     contains  admin   set role  root
```

The output of the `show aaa server-group <group-name>` command includes the following parameters:

Parameter	Description
Name	Specifies if the server is in service or out-of-service.
Server-Type	If enabled, user information in an authentication request is edited before the request is sent to the server.
trim-FQDN	If enabled, user information in an authentication request is edited before the request is sent to the server.

Parameter	Description
Match-Type	<p>If the match type is authstring the authentication server associates with a match rule that the controller can compare with the user/client information in the authentication request. A fdqn match type associates the authentication server with a specified domain. An authentication request is sent to the server only if there is an exact match between the specified domain and the <domain> portion of the user information sent in the authentication request.</p>
Match-Op	<p>This is the match method by which the string in Match-Str is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> ■ contains – The rule is applied if and only if the attribute value contains the string in parameter Operand. ■ starts-with – The rule is applied if and only if the attribute value returned starts with the string in parameter Operand. ■ ends-with – The rule is applied if and only if the attribute value returned ends with the string in parameter Operand. ■ equals – The rule is applied if and only if the attribute value returned equals the string in parameter Operand. ■ not-equals – The rule is applied if and only if the attribute value returned is not equal to the string in parameter Operand. ■ value-of – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied
Match-Str	<p>This is the string to which the value of the returned attribute is matched.</p>
Priority	<p>The priority in which role or VLAN derivation rules are applied. Rules at the top of the list are applied before rules at the bottom.</p>
Attribute	<p>For role or VLAN derivation rules, this is the attribute returned by the authentication server that is examined for Operation and Operand match.</p>
Operation	<p>For role or VLAN derivation rules, this is the match method by which the string in Operand is matched with the attribute value returned by the authentication server.</p> <ul style="list-style-type: none"> ■ contains – The rule is applied if and only if the attribute value contains the string in parameter Operand. ■ starts-with – The rule is applied if and only if the attribute value returned starts with the string in parameter Operand. ■ ends-with – The rule is applied if and only if the

Parameter	Description
	<p>attribute value returned ends with the string in parameter Operand.</p> <ul style="list-style-type: none"> ■ equals – The rule is applied if and only if the attribute value returned equals the string in parameter Operand. ■ not-equals – The rule is applied if and only if the attribute value returned is not equal to the string in parameter Operand. ■ value-of – This is a special condition. What this implies is that the role or VLAN is set to the value of the attribute returned. For this to be successful, the role and the VLAN ID returned as the value of the attribute selected must be already configured on the controller when the rule is applied.
Operand	For role or VLAN derivation rules, this is the string to which the value of the returned attribute is matched.
Action	This parameter identifies whether the derivation rule sets a server group role (set role) or a VLAN (set vlan).
Value	Sets the user role or VLAN ID to be assigned to the client if the rule condition is met.

```

The output of the `show aaa state configuration` command includes the following parameters:

Parameter	Description
Switch IP	IP address of the managed device.
Master/Conductor IP	IP address of Mobility Conductor.
Switch Role	Role assigned to the device.
Current/Max/Total IPv4 Users	Current number of IPv4 users on the managed device/Maximum number of IPv4 users that can be assigned to the managed device at any time/Total number of IPv4 users that have been assigned to the managed device since the last managed device reboot.
Current/Max/Total IPv6 Users	Current number of IPv6 users on the managed device/Maximum number of IPv6 users that can be assigned to the managed device at any time/Total number of IPv6 users that have been assigned to the managed device since the last managed device reboot.
Current/Max/Total Users	Current number of users on the managed device/Maximum number of users that can be assigned to the managed device at any time/Total number of users that have been assigned to the managed device since the last managed device reboot.
Current/Max/Total Stations	Current number of stations registered with the controller/Maximum number of stations that can be registered with the controller at any time/Total number of stations that have registered the controller since the last controller reboot.
Captive Portal Users	Number of current users authenticated via captive portal.
802.1X Users	Number of current users authenticated via 802.1X authentication.
VPN Users	Number of current users authenticated via VPN authentication.
MAC Users	Number of current users authenticated via MAC authentication.

Parameter	Description
Stateful 802.1X Users	Number of current users authenticated via stateful 802.1X authentication.
Tunneled users	Number of stations in tunneled forwarding mode, where 802.11 frames are tunneled to the managed device using generic routing encapsulation (GRE).
Configured user roles	Number of configured user roles.
Configured session ACL	Number of configured session ACLs.
Configured destinations	Number of destinations configured using the netdestination command.
Configured services	Number of service aliases configured using the netservice command.
Configured Auth servers	Number of configured authentication servers.
Auth server in service	Number of authentication servers currently in service.
Radius server timeouts	Number of times the RADIUS server did not respond to the authentication request.
Web	Total number of captive portal authentications or authentication failures since the last managed device reset.
MAC	Total number of MAC authentications or authentication failures since the last managed device reset.
VPN	Total number of VPN authentications or authentication failures since the last managed device reset.
802.1X	Total number of 802.1X authentications or authentication failures since the last managed device reset.
Krb	Total number of Kerberos authentications or authentication failures since the last managed device reset.
RadAcct	Total number of RADIUS accounting verifications or accounting failures since the last managed device reset.
SecureID	Number of authentication verifications or failures using methods which use one-time passwords. (For example, EAP-GTC being used as the inner EAP protocol of EAP-PEAP.)
Stateful-802.1X	Total number of Stateful 802.1X authentications or authentication failures since the last managed device reset.
Management	Total number of Management user authentications or authentication failures since the last managed device reset.

Parameter	Description
Idled users	Total number of users that are not broadcasting data to an AP.
Mobility	Shows whether the IP mobility feature has been enabled or disabled on the managed device.
Fast age	This parameter shows if fast aging of user table entries has been enabled or disabled. When this feature is enabled, if a device comes up on the network with a different IP address, the device's old IP address is immediately deleted. If the user fast-age feature is not configured, the controller retains up to two IPv4 and two IPv6 addresses per device, and these IPs are aged out only when the device becomes inactive.
Per-User Log	Shows if the managed device collects per-user log files for debugging. NOTE: This option is enabled using the aaa log command.
Bandwidth contracts	Number of configured bandwidth contracts on the managed device.
IP takeovers	Number of times a two different stations have attempted to use the same IP address (IP spoofing).
Ping/SYN/Session attacks	Number of reported ping, SYN and session attacks.

Command History

show aaa state debug-statistics

```
show aaa state debug statistics
```

Description

Displays debug statistics for controller authentication, authorization and accounting.

Example

The following example displays debug statistics for a variety of authentication errors:

```
(host) #show aaa state debug-statistics
user miss: ARP=47, 8021Q=5216, non-IP=0, zero-IP=0, loopback=0
user miss: mac mismatch=0, spoof=269 (74), drop=390, ncfg=0
user miss: non-auth opcode=0, no-l2-user=0, l2tp=0, vrrp=0, special mac=0,
iap 13 user=0
Idled users = 3376
Idled users due to MAC mismatch = 0
Idled users due to SOS: wireless tunnel=0 wireless dtunnel=0
Idled users due to SOS: wired tunnel=0 wired dtunnel=0
Idled users due to SOS: other=0
Idled users due STM deauth: tunnel=0 dtunnel=0
Idled users from STM timeout: tunnel=0 dtunnel=0
Idled users from STM: other=0
Current users with STM idle flag = 0
Idle messages: SOS=0 STM deauth=0 STM timeout=0
Logon lifetime iterations = 4501, entries deleted = 121
SIP authentication messages received 29227, dropped 29227
Missing auth user deletes: 0
Captive-portal forced user deletes: 1
Mobility Stats
    INTRA_MS 0, MAC mismatch 0, HA mismatch 0
    INTER_MS 0, MAC mismatch 0, HA mismatch 0
    MIP Update 0, Move 0, Del 0, TunAcl 0
    AAA Done 0, Del 2
    IPIP Loop forced Del: 0, Validate Visitor 0
Auth User rejects Received
L2 User:0, IPV4 :0, IPV6:0
Auth User rejects Processed
L2 User:0, IPV4 :0, IPV6:0
```

The **show aaa state debug-statistics** command also displays the number of VIA VPN sessions initiated beyond the assigned limit:

```
(host) [mynode] #show aaa state debug-statistics | include VIA
VIA max session limit exceeded errors: 2
```

The output of this command includes the following parameters:

Parameter	Description
User Miss	
ARP	Number of ARP packets sent between the datapath and the controlpath.
8021q	Number of 802.1q (VLAN tag) packets sent between the datapath and the controlpath.
non-ip	Number of non-IP type packets sent between the datapath and the controlpath.
zero-ip	Number of packets sent without an internet protocol (IP).
loopback	If 1 , the controller has a defined loopback address. If 0 , a loopback address has not yet been configured.
mac mismatch	Number of users that were not authenticated due to MAC mismatches.
spoof	Number of users that were not authenticated due to spoofed IP addresses.
drop	Number of user authentication attempts that were dropped.
ncfg	Number of packets sent between datapath and controlpath, where the authentication module has not completed the initialization required to process the traffic.
Non-auth opcode	Number of packets whose opcode is non-auth opcode. This is a check to find if auth is responsible for processing received packet.
No-l2-user	Number of user packets dropped due to absence of an L2 entry for the user.
l2tp	Number of l2tp users.
vrrp	Number of VRRP users.
special mac	Number of users with a special MAC address.
iap	Number of instant AP users.
idled users	Number of inactive stations that are not broadcasting data to an AP.
idled users due to MAC mismatch	For internal use only.
Idled users due to SOS	

Parameter	Description
wireless tunnel	Number of wireless users in tunnel forwarding mode that were aged out by the controller.
wireless dtunnel	Number of wireless users in decrypt tunnel forwarding mode that were aged out by the controller.
wired tunnel	Number of wired users in tunnel forwarding mode that were aged out by the controller.
wired dtunnel	Number of wired users in decrypt tunnel forwarding mode that were aged out by the controller.
Other	Number of users using modes other than tunneled or Decrypt tunneled aged out by the controller.
Idled users due STM deauth	
tunnel	Number of users in tunnel forwarding mode that aged out after STM deauthentication, and timer expiration.
dtunnel	Number of users in decrypt tunnel forwarding mode that aged out after STM deauthentication, and timer expiration.
Idled users from STM timeout	
tunnel	Number of users in tunnel forwarding mode that aged out after the STM timer expired.
dtunnel	Number of users in decrypt tunnel forwarding mode that aged out after the STM timer expired.
Idled users from STM	
other	Number of users in forwarding modes other than decrypt tunnel or tunnel mode that aged out after the STM timer expired.
Logon lifetime iteration	Number of users deleted for lack of activity.
SIP authentication message	Number of session initiation protocol (SIP) authentication messages received.
Missing auth user deletes	Number of users removed from the datapath by the auth module, even without a mapping entry in control path. This counter can help identify problems with messages sent between the controlpath and the datapath.
Mobility Stats	Number of different messages exchanged between the mobile IP and the auth module. This is used for troubleshooting purposes only.

Parameter	Description
<code>Captive-portal forced user deletes</code>	Number of idle users deleted after captive portal authentication.
Auth User Rejects Received	
<code>L2 User</code>	Number of authentication rejects received for L2 users from the datapath due to a failure of the operation.
<code>IPv4</code>	Number of authentication rejects received for IPv4 users from the datapath due to a failure of the operation.
<code>IPv6</code>	Number of authentication rejects received for IPv6 users from the datapath due to a failure of the operation.
Auth User Rejects Processed	
<code>L2 User</code>	Number of authentication rejects for L2 users that were processed after the reject was received.
<code>IPv4</code>	Number of authentication rejects for IPv4 users that were processed after the reject was received.
<code>IPv6</code>	Number of authentication rejects for IPv6 users that were processed after the reject was received.

show aaa state log

show aaa state log [info]

Description

Displays global log files for AAA events. If you have enabled per-user logging using the [aaa log](#) command, the output of this command displays global AAA log files for events that are not triggered by individual user authentication, such as AP authentication and the initial pre-authentication processes that occur before a client authenticates to the controller.

To display log files for events triggered by a specific user, use the command [show user](#) or `show ipv6 user-table ip <ipv6-addr> log`.

Parameter	Description
info	This parameter displays debugging information for internal use only.

Example

The example below shows a partial list of the global log files displayed by the `show aaa state log` command..

```
(host) #show aaa state log
1: At Thu Apr 11 10:41:27: [L] Type cert-downloaded * id 0 len 0,
  bssid 00:00:00:00:00:00 | mac: 00:00:00:00:00:00
2: At Thu Apr 11 10:43:17: [L] Type ap-up * id 0 len 0,
  bssid 6c:f3:7f:5f:2c:b0 | mac: 00:00:00:00:00:00
3: At Thu Apr 11 10:43:17: [L] Type ap-up * id 0 len 0,
  bssid 6c:f3:7f:5f:2c:a0 | mac: 00:00:00:00:00:00
4: At Thu Apr 11 10:43:50: [L] Type station-term-start * id 10 len 0,
  bssid 6c:f3:7f:5f:2c:a0 | mac: 50:a4:c8:bd:be:41
5: At Thu Apr 11 10:43:50: [L] Type station-data-ready_ack * id 10 len 0,
  bssid 00:00:00:00:00:00 | mac: 50:a4:c8:bd:be:41
```

show aaa state mux-tunnel

Description

Displays multiplexer (MUX) tunnel IDs.

Example

The example below shows statistics for one MUX tunnel

```
(host) #show aaa state mux-tunnel
Mux Tunnel Information
-----
      IP           Tunnel ID      Slot/Port  AP Type  AP Name
-----
10.2.1.26          1/1                1
```

The output of this command includes the following parameters:

Parameter	Description
IP	IP address of a multiplexer (MUX) server
Tunnel ID	ID number of a MUX tunnel.
Slot/Port	The slot and port used by the controller, in the format <slot>/<module>/<port>
AP Type	AP model type.
AP Name	Name of an AP.

show aaa state station

```
show aaa state station <A:B:C:D:E:F>
```

Description

Displays AAA statistics for a station.

Parameter	Description
<A:B:C:D:E:F>	MAC address of a station.

Example

The example below shows statistics for a station with four associated user IP addresses. The output of this command shows station data, the AAA profiles assigned to the station, and the station's authentication method.

```
(host) #show aaa state station 00:21:5c:85:d0:4b

show aaa tacacs-accounting

show aaa tacacs-accounting

Description

Displays TACACS accounting configuration.

Example

The example below shows that TACACS accounting has been enabled, and that the TACACS server is in the server group acct-server.

```
(host) #show aaa tacacs-accounting
TACACS Accounting Configuration
-----
Parameter  Value
-----  ----
Mode       Enabled
Server-Group acct-server
```

The output of this command includes the following parameters:

Parameter	Description
Mode	Shows if the TACACS accounting feature is enabled or disable
Server-Group	The server group that contains the active TACACS server.

Related Commands

Command	Description
aaa tacacs-accounting	This command configures reporting of commands issued from a managed device to a TACACS+ server group.

show aaa timers

```
show aaa timers
```

Description

Displays AAA timer values.

Example

The example below shows that the controller has all default timer values:

```
(host) #show aaa timers
User idle timeout = 6 minutes
Auth Server dead time = 10 minutes
Logon user lifetime = 5 minutes
```

Related Commands

Command	Description
aaa timers	This command configures the timers that you can apply to clients and servers.

show aaa user-delete-result

```
show aaa user-delete-result
```

Description

This command displays the list of users deleted for the last twenty delete requests issued from the Managed devices. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following command displays the user deleted from the Managed Devices,

```
(host)[mynode] (config) #show aaa user-delete-result
Summary of user delete CLI requests !
Current user delete request timeout value: 300 seconds

aaa user delete 1.2.3.4 , Overall Status- Complete , Total users deleted- 0
MD IP : 10.9.196.168, Status- Complete , Count- 0
MD IP : 10.3.67.30, Status- Complete , Count- 0
```

Related Commands

show aaa web admin-port

```
show aaa web admin-port
```

Description

Displays the port numbers of HTTP and HTTPS ports used for web administration.

Example

The example below shows that the controller is configured to use HTTPS on port 4343 or 443, and HTTP on port 8888.

```
(host) #show aaa web admin-port
https port = 4343
http port = 8888
```

show aaa xml-api server

```
show aaa xml-api server [<server_ip>]
```

Description

Displays a list of XML servers used for authentication, authorization, and accounting.

Parameter	Description
<server_ip>	IP address of an XML API server. Include this parameter to see if a secret key is configured for the specified server.

Example

The output of this command shows that the Mobility Conductor has two configured XML API servers that are each referenced by two different AAA profiles. Note that user-defined servers will not have an entry in the **Profile Status** column.

```
(host) #show aaa xml-api server

XML API Server List
-----
Name    References Profile Status
-----
10.1.2.3 2
10.4.3.2 2
```

Related Commands

show aaa xml-api statistics

show aaa xml-api statistics

Description

Displays statistics for an external XML API server. Issue this command to troubleshoot AAA problems and monitor usage on an XML server.

Parameter	Description
<server_ip>	IP address of XML API server.

Example

The example below shows AAA statistics for an external XML server with the IP address 10.1.2.3. This command shows the number of times that a particular event has occurred per client. The first number is the number of times this event occurred. The number of new events since the last time the counters were displayed is shown in parentheses.

```
(host) #show aaa xml-api statistics

ECP Commands Statistics
-----
Server user_authenticate user_add user_delete user_denylist user_query
user_logout
-----
-----
ECP Errors Statistics
-----
Server UnkUser UnkRole UnkExtAgent AuthFail InvCmd InvMsgAuth
InvMsgDig MsgAuthMiss InvVerNo IntErr ClntNotAuthz VlanIP InvIP
SwitchIP MacAddrMiss UnsuppCmd OperTimeout
-----
-----
Packets received from unknown clients : 0 (0)
Packets received with unknown request : 0 (0)
Requests Received/Success/Failed      : 0/0/0 (0/0/0)
```

The output of this command includes the following parameters:

Parameter	Description
user_authenticate	Number of users authenticated on the XML server since the last controller reboot.
user_add	Number of users added to the controller's user table.
user_delete	Number of users removed from the controller's user table.
user_blacklist/user_denylist	Number of denied user association requests.
user_query	Number of user queries performed.
unknown user	Number of unknown users.
unknown role	Number of unknown user roles.
unknown external agent	Number of requests by an unknown external agent.
authentication failed	Number of failed authentication requests.
invalid command	Number of invalid XML commands
invalid message authentication method	Number of XML commands with an invalid authentication method (when a key is configured on the controller).
invalid message digest	Number of XML commands with an invalid digest type (when a key is configured on the controller).
missing message authentication	Number of XML commands with an missing authentication method (when a key is configured on the controller).
missing or invalid version number	Number of commands with a missing or invalid version number. The version number should always be 1.0.
internal error	Number of internal server errors
client not authorized	Number of unauthorized clients
Cant use VLAN IP	Number of time a user IP is same as the VLAN IP.
Invalid IP	Number of XML commands with an invalid IP address.
Cant use Switch IP	Redirection to a IP failed, possibly because the source IP has been NATted.

Parameter	Description
missing MAC address	Number of XML commands with a missing MAC address.
Packets received from unknown clients	Number of packets received from unknown clients.
Packets received with unknown request	Number of packets received with unknown request
Requests Received/Success/Failed	Total number of requests received / number of successful requests / number of failed requests

Command History

Command	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.0.0.0	Command introduced.

All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show acl ace-table

```
show acl ace-table {ace <0-7680>}|{acl <1-2699>}|{all}
```

Description

Displays an access list entry (ACE) table for an ACL.

Parameter	Description
ace <0-7680>	Shows a single ACE entry.
acl <1-2699>	Shows all ACE entries for a single ACL.
all	Shows all ACE entries.

Example

The following example shows that there are eighteen access control entries for ACL 1.

```
(host) #show acl ace-table acl 1
1020: any any 1 0-65535 0-65535 f80001:permit
1021: any any 17 0-65535 53-53 f80001:permit
1022: any any 17 0-65535 8211-8211 f80001:permit
1023: any any 17 0-65535 8200-8200 f80001:permit
1024: any any 17 0-65535 69-69 f80001:permit
1025: any any 17 0-65535 67-68 f80001:permit
1026: any any 17 0-65535 137-137 f80001:permit
1027: any any 17 0-65535 138-138 f80001:permit
1028: any any 17 0-65535 123-123 f80001:permit
1029: user 10.6.2.253 255.255.255.255 6 0-65535 443-443 f80001:permit

show acl acl-table

```
show acl acl-table  
  <1-2699>  
  verbose
```

Description

Displays information for a specified ACL.

Parameter	Description
acl-table <1-2699>	Specify the number of the ACL for which you want to view information.
verbose	Show verbose ACL information.

Example

The following example displays the ACL table for the controller:

```
(host) #show acl acl-table 1  
  
AcLTable  
-----  
ACL  Type  ACE Index  Ace Count  Name  Applied  
---  ---  -----  -  
1    role  1459      18         logon  0  
  
Total free ACE entries = 3591  
Free ACE entries at the bottom = 2552  
Next ACE entry to use = 1480 (table 1)  
Ace entries reused 622 times  
ACL count 64, tunnel acl 0  
  
Ace entries reused 373 times  
ACL count 64, tunnel acl 0
```

The output of this command displays the following parameters:

Parameter	Description
ACL	Number of the specified ACL
Type	Shows the ACL type: <ul style="list-style-type: none">■ role: Access list is used to define a user role.■ mac: MAC ACLs allow filtering of non-IP traffic. This ACL filters on a specific source MAC address or range of

Parameter	Description
	MAC addresses. <ul style="list-style-type: none"> ■ session: Session ACLs define traffic and firewall policies on the controller. ■ ether-type: This type of ACL filters on the Ethertype field in the Ethernet frame header, and is useful when filtering non-IP traffic on a physical port. ■ standard: Standard ACLs are supported for compatibility with router software from other vendors. This ACL permits or denies traffic based on the source address of the packet.
ACE Index	Starting index entry for the ACL's access control entries
ACE Count	Number of access control entries in the ACL
Name	Name of the ACL.
Applied	Number of times the ACL was applied to a role.
Total free ACE entries	The total number of free ACE entries. This includes available ACE entries at the bottom of the list, as well as free ACE entries in the middle of the table from previous access list entries that were later removed.
Free ACE entries at the bottom	The total number of free ACE entries at the bottom of the list.
Next ACE entry to use	Ace number of the first free entry at the bottom of the list.
ACE entries reused	For internal use only.
ACL count	Total number of defined ACLs
Tunnel ACL	Total number of defined tunnel ACLs.

The following example displays the ACL table in verbose mode:

```
(host) [mynode] #show acl acl-table verbose
AclTable
-----
ACL  Type          ACE Index  Rule Count  Ace Count  Name
    Applied  Alias-Rule-Hits
---  ---
-----
1    session      0          0           1          global-sacl
    0          Disabled
2    role         535        32          33         logon
    0          Disabled
3    session      241        11          12         validuser
    0          Disabled
```

```

4    session      0      0      1      sdn-acl

Total free hits table indices = 16384
Free hits table indices at the bottom = 16384
Next hits table index entry to use = 0 (table 1, toggle-count 2)

```

The output of this command displays the following parameters:

Parameter	Description
ACL	Number of the specified ACL.
Type	Shows the ACL type: <ul style="list-style-type: none"> ■ role: Access list is used to define a user role. ■ session: Session ACLs define traffic and firewall policies on the controller. ■ route: Name of the route for which you want to record advanced debugging information.
ACE Index	Starting index entry for the ACL's access control entries.
Rule Count	Total rule count of ACLs.
ACE count	Number of access control entries in the ACL.
Name	Name of the ACL.
Applied	Number of times the ACL was applied to a role.
Alias-Rule-Hits	Total number of alias rule hits.
Total Ace entries in use	Total number of ACE entries in the table.
Total free ACE entries	The total number of free ACE entries. This includes available ACE entries at the bottom of the list, as well as free ACE entries in the middle of the table from previous access list entries that were later removed.

Parameter	Description
Free ACE entries at the bottom	The total number of free ACE entries at the bottom of the list.
Next ACE entry to use	ACE number of the first free entry at the bottom of the list.
ACE entries reused	For internal use only.
ACL count	Total number of defined ACLs.
Tunnel ACL	Total number of defined tunnel ACLs.
ACE table toggle count	ACE table toggles between those banks on configuration events, and the toggle count is a counter for that operation.
Total hits table indices in use	Count that represents the hits-table indices used by ACEs with netdestinations.
Total free hits tables indices	The total number of free hits-table entries.
Free hits table indices at the bottom	The total number of free hits-indices at the bottom of the table.
Next hits table index entry to use	Hits-table index of the first free entry at the bottom of the table.

show acl hits

```
show acl hits
```

Description

Displays internal ACL hit counters. Issue this command to see the number of times an ACL defined a user's role, or traffic and firewall policies for a user session.

Example

In the example below, the output of the *User Role ACL Hits* table is shown in two separate tables to allow the output to fit on a single page of this document. In the actual controller CLI, the *User Role ACL Hits* table is shown in a single, wide table.

```
(host) #show acl hits
User Role ACL Hits
-----
Role          Policy          Src          Dst
----          -

```

The output of this command includes the following information:

Parameter	Description
Role	Name of the role assigned by the ACL.
Policy	Name of the policy used by the ACL
Src	The traffic source, which can be one of the following: <ul style="list-style-type: none"> ■ <alias>: Name of a user-defined alias for a network host, subnetwork, or range of addresses. ■ any: match any traffic. ■ host: specify a single host IP address. ■ network: specify the IP address and netmask. ■ user: represents the IP address of the user.
Dst	The traffic destination, which can be one of the following: <ul style="list-style-type: none"> ■ <alias>: Name of a user-defined alias for a network host, subnetwork, or range of addresses. ■ any: match any traffic. ■ host: specify a single host IP address. ■ network: specify the IP address and netmask. ■ user: represents the IP address of the user.
Service	Network service, which can be one of the following: <ul style="list-style-type: none"> ■ IP protocol number (0-255) ■ name of a network service (use the show netservice command to see configured services) ■ any: match any traffic ■ tcp: specify the TCP port number (0-65535) ■ udp: specify the UDP port number (0-65535)
Action	Action if rule is applied, which can be one of the following: <ul style="list-style-type: none"> ■ deny: reject packets ■ dst-nat: perform destination NAT on packets ■ dual-nat: perform both source and destination NAT on packets ■ permit: forward packets ■ redirect: specify the location to which packets are redirected ■ src-nat: perform source NAT on packets
Dest/Opcode	The datapath destination ID.

Parameter	Description
New Hits	Number of ACL hits that occurred since this command was last issued.
Total Hits	Total number of ACL hits recorded since the controller last reset.
Index	Index number of the ACL.
ACL	ACL number
ACE	ACE number
New Hits	Number of times the ACL was applied since this command was last issued.
Total Hits	Number of times the ACL was applied since the controller was last reset.
Index	Index number of the ACL.

Command History

show activate

show activate

Description

This command displays the profile that allows a managed device to synchronize its remote AP whitelist/allowlist with the Aruba Activate cloud-based services.

Use this command to view the credentials the managed device uses to synchronize the remote AP whitelist/allowlist with an Activate server.

Example

The following example displays the Activate whitelist/allowlist service settings:

```
(host)[node](config)# show activate
activate
-----
Parameter                               Value
Set                                       -----
---
Activate AP Whitelist/Allowlist Service   nabled
Activate Device Whitelist/Allowlist Service nabled
Activate URL                              https://activate.arubanetworks.com
Provision Activate URL                    https://device.arubanetworks.com
Activate Login Username                   ztp
Activate Login Password                   *****
Periodic Interval for WhiteList Download  1
Add-Only Operation                        Enabled
Custom cert to upload to Activate         N/A
Server cert to be used for IPSEC          N/A
```

The **Periodic Interval for WhiteList/Allowlist Download** parameter indicates the whitelist/allowlist download period in days.

Related Commands

Parameter	Description
activate	This command synchronizes the remote AP whitelist/allowlist on the managed device with the Activate whitelist/allowlist database.

Command History

Release	Modification
ArubaOS 8.9.0.0	The following terminologies are updated: <ul style="list-style-type: none">▪ All instances of <code>master</code> have been replaced with <code>conductor</code>.▪ All instances of <code>whitelist</code> have been replaced with <code>allowlist</code>.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Config or enable mode on Mobility Conductor.

show adp config

```
show adp config
```

Description

Displays Aruba Discovery Protocol (ADP) configuration settings.

Example

The following example shows that the managed device has all default settings for ADP.

```
(host) [mynode] (config) #show adp config
ADP Configuration
-----
key          value
---          -
discovery    enable
igmp-join    enable
igmp-vlan    0
```

The output of this command includes the following parameters:

Parameter	Description
discovery	Aruba APs send out periodic multicast and broadcast queries to locate Mobility Conductor. If the APs are in the same broadcast domain as Mobility Conductor and ADP is enabled on the managed device, the managed device automatically responds to the APs' queries with its IP address. This command shows whether ADP is enabled or disabled on the managed device.
igmp-join	Shows whether the managed device has enabled or disabled the sending of Internet Group Management Protocol (IGMP) join requests.
igmp-vlan	ID of the VLAN to which IGMP reports are sent. If this value is set to 0, the managed device will use the default route VLAN used.

Related Commands

show adp counters

```
show adp counters
```

Description

Displays Aruba Discovery Protocol (ADP) counters.

Example

The following example shows the ADP counter table for the managed device.

```
(host)[mynode](config) #show adp counters
ADP Counters
-----
key          value
---          -
IGMP Join Tx 1
IGMP Drop Tx 0
ADP Tx       0
ADP Rx       0
```

The output of this command includes the following parameters:

Parameter	Description
IGMP Join Tx	Number of Internet Group Management Protocol (IGMP) join requests sent by the managed device.
IGMP Drop Tx	Number of Internet Group Management Protocol (IGMP) drop requests sent by the managed device.
ADP Tx	Number of ADP responses sent to APs.
ADP Rx	Number of multicast and broadcast queries received from APs trying to locate Mobility Conductor.

<p><u>cppm-server</u></p> <p>aaa query-interval radius statistics rfc3576 statistics</p>	<p>Shows ClearPass Policy Manager server details.</p> <ul style="list-style-type: none"> ▪ aaa: Shows the AAA parameters for AirGroup. ▪ query-interval: Shows the query interval used to refresh the ClearPass Policy Manager entries at periodic intervals. ▪ radius statistics: Shows the RADIUS statistics. This command is node specific. ▪ rfc3576 statistics: Shows the dynamic authorization extensions to RADIUS statistics. This command is node specific.

Parameter	Description
domain	Shows the IP address of participating managed devices.
effective profiles	Shows the effective profiles that are applied at that node. NOTE: This command is node specific.
flow-table	Shows the flows installed by AirGroup process. NOTE: This command is node specific.
internal-state statistics dlna mdns ppm{daily hourly minutes weekly <count>} verbose	Shows internal state of AirGroup process. <ul style="list-style-type: none"> ▪ dlna - Shows the DLNA statistics. ▪ mdns - Shows the mDNS statistics. ▪ ppm - Shows packet per minute statistics. ▪ verbose - Shows additional details of the statistics. NOTE: This command is not node specific.
multi-controller-table dlna mdns verbose	Show the AirGroup cluster information. <ul style="list-style-type: none"> ▪ dlna - Shows DLNA statistics. ▪ mdns - Shows mDNS statistics, ▪ verbose - Shows additional details of the statistics. NOTE: This command is not applicable when Mobility Conductor is a VM. NOTE: This command is supported only on stand-alone controller domain.
packet-capture	Show packet capture in one of the following formats: <ul style="list-style-type: none"> ▪ hex: Show packet capture in HEX format ▪ in-pkt: Show packet capture received (RX). ▪ mac: Show packet capture filter with MAC address. ▪ out-pkt: Show packet capture sent (TX). ▪ tcpdump-options: Show packet capture

Parameter	Description
	filter tcpdump options. <ul style="list-style-type: none"> ▪ write-to-flash: Save packet capture to ag.pcap. ▪ <count>: Show last count rows.
<u>policy-entries</u> mac neighborhood <mac> <mac>	Show the active policies. <ul style="list-style-type: none"> ▪ neighborhood - Shows the AP neighborhood to discover the server. ▪ mac - Shows active policies filtered by specified MAC address. <p>NOTE: This command is not node specific.</p>
<u>query-result</u>	Shows the list of servers available for the query sent.
<u>servers</u> dlna mdns verbose	Shows the server table. <ul style="list-style-type: none"> ▪ dlna - Shows the DLNA servers. ▪ mdns - Shows the mDNS servers. ▪ verbose - Shows additional information of the AirGroup servers. <p>NOTE: This command is node specific.</p>
<u>status</u>	Shows the current status of the AirGroup configuration and configured AirGroup services. <p>NOTE: This command is node specific.</p>
switches	Shows the switch entries. <p>NOTE: This command is node specific.</p>
<u>tracebuf</u> msgs [ip <ipaddr>][mac <macaddr>] pps	Shows the trace buffer. <ul style="list-style-type: none"> ▪ msgs - Shows the AirGroup trace buffer. ▪ pps - Shows the packet arrival trace buffer. <p>NOTE: This command is not node specific.</p>
thread-statistics	Shows mdns/dlna packet statistics per thread.
<u>users</u> dlna	Shows user table.

Parameter	Description
mdns verbose	<ul style="list-style-type: none"> ▪ dlna - Shows the DLNA users. ▪ mdns - Shows the mDNS users. ▪ verbose - Shows additional information of users. <p>NOTE: This command is node specific.</p>
vlan	<p>Shows the status of all the disallowed VLANs.</p> <p>NOTE: This command is node specific.</p>

Example

The following example shows the current status of the AirGroup configuration and configured AirGroup services:

```
(host) [mynode] #show airgroup status

AirGroup Information
-----
Feature                Status
-----                -
MDNS                   Disabled
DLNA                   Enabled
Enforce Registration   Disabled
IPV6                   Enabled

AirGroup Service Information
-----
Service                Status
-----                -
remotemgmt             Disabled
DIAL                   Enabled
AmazonTV               Enabled
DLNA Media             Enabled
test                   Enabled
static                 Enabled
combined               Enabled
DLNA Print             Disabled
allowall               Enabled
sharing                Disabled
chat                   Disabled
Daniel                 Enabled
itunes                 Disabled
airplay                Enabled
airprint               Enabled
googlecast             Enabled
```

The following example displays the packets sent and received per second by AirGroup:

(host) [mynode] #show airgroup internal-state statistics

Related Commands

Command	Description
airgroup	This command configures AirGroup settings.
airgroupprofile	This command configures an AirGroup profile.
show airgroupprofile	This command shows the AirGroup profile settings.

Command History

Release	Modification
ArubaOS 8.7.0.0	New sub-parameter <code>ppm</code> is added to the <code>internal-state statistics</code> parameter.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airgroup active-domains

```
show airgroup active-domains
```

Description

This command shows the list of configured AirGroup active-domains. This command is applicable only on stand-alone controllers.

Example

The following example shows the list of configured AirGroup active-domains:

```
(host) [mynode] #show airgroup active-domains

AirGroup Active-Domains
-----
Domain Name  Status
-----
Campus1     Included
Campus2     Included

Num active-domains:2
```

The output of this command includes the following parameters:

Parameter	Description
Domain Name	Shows the name of the domain.
Status	Shows the status of the domain if it is part of the active-domain list.

Related Commands

Command	Description
airgroup	This command configures AirGroup settings.
airgroupprofile	This command configures an AirGroup profile.

Command	Description

show airgroupprofile	This command shows the AirGroup profile settings.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on stand-alone controller.

show airgroup aps

show airgroup aps

Description

This command shows the AP tables.

Example

The following example shows the AP tables:

```
(host) [mynode] #show airgroup aps

AirGroup APs
-----
IP   Name      Group      MAC          BSSID- A      BSSID- B/G

                        40:e3:d6:bf:65:50 A

Num APs:3
```

The output of this command includes the following parameters:

Column	Description
IP	Shows the IP address of the AirGroup AP.
Name	Shows the name of the AP.
Group	Shows the group of the AirGroup user.
MAC	Shows the MAC address of the AirGroup AP.
BSSID- A	Shows the BSSID-A of the AirGroup AP.
BSSID- B/G	Shows the BSSID-B/G of the AirGroup AP.

Column	Description
FQLN	Shows the FQLN of the AirGroup AP.
Neighbor count- A	Shows the neighbor count-A of the AirGroup AP.
Neighbor count- B/G	Shows the neighbor count-B/G of the AirGroup AP.
Neighbor AP name	Shows the name of the neighbor AP (if available) or the BSSID of the neighbor AP.
BAND	Shows the band of the AirGroup AP.

Related Commands

Command	Description
airgroup	This command configures AirGroup settings.
airgroupprofile	This command configures an AirGroup profile.
show aigroup	This command shows the global AirGroup settings.
show aigroupprofile	This command shows the AirGroup profile settings.

Command History

Release	Modification
ArubaOS 8.4.0.0	Updated the description of parameter, Neighbor AP name.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airgroup blocked-queries

```
show airgroup blocked-queries [dlna|mdns]
```

Description

This command shows the service ID that was queried but not available in the AirGroup service table.

Parameter	Description
dlna	Shows the DLNA blocked queries.
mdns	Shows the mDNS blocked queries.

Example

The following example displays the service ID that was queried but not available in the AirGroup service table:

```
(host) [mynode] #show airgroup blocked-queries

AirGroup dropped Query IDs
-----

10.16.124.236             _uscan._tcp               40
10.16.126.248             _keepalive._dns-sd._udp  20
Num Blocked Service-ID:4
```

The output of this command includes the following parameters:

Column	Description
Origin	Shows the source IP address of the AirGroup server that advertises this service.
Service ID	Shows the blocked service ID of the server.
#response-hits	Shows the number of response messages received for this service ID.

show airgroup cache entries

```
show airgroup cache entries [debug|dlna|mac|mdns|static|verbose]
```

Description

This command shows the AirGroup mDNS and DLNA resource records in cache.

Parameter	Description
debug	Shows debug information.
dlna	Shows the DLNA cache entries.
mac	Shows entries filtered on a specific MAC address of the server.
mdns	Shows the mDNS cache entries.
static	Shows static cache entries.
verbose	Shows details cache entries.

Example

The following example shows the AirGroup mDNS resource records in the cache:

```
(host) [mynode] #show airgroup cache entries mnds

Cache Entries
-----
Name                Type  Class  TTL   Origin  Expiry  Last Update
-----
world_cricket       A     IN     120   0.0.0.0  static  N/A
_icct20._tcp.local PTR   IN     4500  0.0.0.0  static  N/A
Num Cache Entries:2
```

The output of this command includes the following parameters:

Column	Description
Name	Shows the name of the Service ID.
Type	Shows the type of mDNS or DLNA record.
Class	Shows the class of the record. This is usually IN.

Column	Description
TTL	Shows the time to live value of the service ID in seconds.
Origin	Shows the source IP of the AirGroup server.
Expiry	Shows the expiry period of the mDNS or DLNA record in seconds.
Last Update	Shows the time stamp of the last cache update.

show airgroup cppm

show airgroup cppm [entries|server-group]

Description

This command shows information for devices registered in ClearPass Policy Manager.

Parameter	Description
entries	Shows the ClearPass Policy Manager registration information.
server-group	Shows the Server Group information.

Example

The following example shows the information for devices registered in ClearPass Policy Manager:

```
(host) [mynode] #show airgroup cppm entries

ClearPass Guest Device Registration Information
-----
Device          device-owner  shared location-id AP-name  shared
location-id AP-FQLN
-----
cc:3a:61:b1:4a:cc  lecturer
c4:85:08:a2:15:1b  N/A
00:1e:65:2d:ae:44  N/A

shared location-id AP-group  shared user-list  shared group-list  shared
role-list  CPPM-Req  CPPM-Resp
-----
          lecturer2
          1          1          DEPT1
          1          1          Physics
          1          1          Chemistry

Num CPPM Entries:3
```

The output of this command includes the following parameters:

Column	Description
Device	Shows the MAC address of the AirGroup device.
device-owner	Shows the user name of the AirGroup device.
shared location-id AP-name	Shows the location ID based on AP name.
shared location-id AP-FQLN	Shows the location ID based on the FQLN value of an AP.
shared location-id AP-group	Shows the location ID based on the name of an AP group.
shared user-list	Shows one or more primary login IDs of an AirGroup user.
shared group-list	Shows one or more primary login IDs of an AirGroup user group.
shared role-list	Shows the name of the role.
CPPM-Req	Shows the number of requests sent to ClearPass Policy Manager to populate the policy details for the given client.
CPPM-Resp	Shows the number of responses received from the ClearPass Policy Manager for the policy details of the given client.

The following example shows the server group information:

```
(host) [mynode] #show airgroup cppm server-group

Airgroup AAA Server Group
-----
Name    Inservice  trim-FQDN  match-FQDN
-----  -
cppm    Yes        No
```

The output of this command includes the following parameters:

Parameter	Description
Name	Shows server group name.
Inservice	Shows in service status of server group.
trim-FQDN	Shows trim FQDN status of server group.
match-FQDN	Shows matching FQDN of server group.

show airgroup cppm-server

```
show airgroup cppm-server {aaa|query-interval|radius statistics|rfc3576 statistics}
```

Description

This command shows the ClearPass Policy Manager server information.

Parameter	Description
<aaa>	Shows AirGroup aaa profile.
query-interval	Shows the ClearPass Policy Manager periodic query interval time. 1 - 24 hours 10 hours
radius statistics	Shows the RADIUS server statistics for AirGroup.
rfc3576 statistics	Shows the RFC3576 server statistics for AirGroup.

Example

The following example shows the AirGroup aaa profile information:

```
(host) [mynode] #show airgroup cppm-server aaa

Airgroup AAA profile
-----
Parameter                               Value           Set
-----
Server Group                             san-dot1x
RFC 3576 server                           10.15.16.39
Configure dead time for a down Server     5
Configure UDP port to receive RFC 3576 server requests. 5999
```

The output of this command includes the following parameters:

Column	Description
Parameter	Shows the parameter name.
Value	Shows the value configured.
Set	Shows the value applied.

The following example shows the ClearPass Policy Manager query interval:

```
(host) [mynode] #show airgroup cppm-server query-interval

CPPM Server Query Interval
-----
Timer Value  Unit
-----  ----
10           hours
```

The output of this command includes the following parameters:

Column	Description
Timer Value	Shows the query interval.
Unit	Shows the unit of the query interval.

The following example shows the RADIUS server statistics:

```
(host) [mynode] #show airgroup cppm-server radius statistics

Airgroup RADIUS Server Statistics
-----
Statistics          cppm_ser01
-----
PAP Requests        30175

show airgroup domain

show airgroup domain

Description

This command shows the list of configured AirGroup domains. This command is applicable only on stand-alone controllers.

Example

The following example shows the list of configured AirGroup domains:

```
(host) [mynode] #show airgroup domain

AirGroup Domains
-----
Name  Description  IP-Address
----  -
test  test         10.15.52.2
10.15.52.16
ag    10.15.52.2
10.15.52.16
Num domains:2
```

The output of this command includes the following parameters:

Column	Description
Name	Shows the name of the AirGroup domain.
Description	Shows a short description of the AirGroup domain.
IP-Address	Shows IP address or VRRP IP address the stand-alone controller.

Related Commands

Command	Description
airgroup	This command configures AirGroup settings.

show airgroup multi-controller-table

```
show airgroup multi-controller-table [dlna|mdns|verbose]
```

Description

This command shows the information of all stand-alone controllers participating in an AirGroup domain. This command is applicable only on stand-alone controllers.

Parameter	Description
dlna	Shows the DLNA statistics.
mdns	Shows the mDNS statistics.
verbose	Shows the detailed statistics.

Example

The following example shows information of all stand-alone controllers participating in an AirGroup domain:

```
(host) [mynode] #show airgroup multi-controller-table

AirGroup Multi-Controller-Table
-----
IP-Address
-----
10.15.52.16
Num IP-Address:1
The following example shows the DLNA statistics all stand-alone controllers
participating in an AirGroup domain:
(host) [mynode] #show airgroup multi-controller-table dlna

AirGroup Multi-Controller-Table verbose
-----
IP-Address   Type   Request with Tag Tx   Unicast Response with tag Tx   Raw
Response Tx   Request with Tag Rx   Unicast Response with tag Rx   Raw Response
Rx
-----
-----
-

0
Num IP-Address:1

```

The following example shows the detailed statistics all stand-alone controllers participating in an AirGroup domain:

```

(host) [mynode] #show airgroup multi-controller-table verbose

AirGroup Multi-Controller-Table verbose
-----
IP-Address   Type  Request with Tag Tx  Unicast Response with tag Tx  Raw
Response Tx  Request with Tag Rx  Unicast Response with tag Rx  Raw Response
Rx
-----
-
10.15.52.16  mDNS  1134                0                               0
0
10.15.52.16  DLNA  448                N/A                             0
0
Num IP-Address:1

```

The output of this command includes the following parameters:

Table 11: *show airgroup multi-controller-table*

Column	Description
IP-Address	Shows the IP address of all stand-alone controllers participating in an AirGroup domain.
Type	Shows the type of record.
Request with Tag Tx	Shows the number of AirGroup queries transmitted with meta-tag information.
Unicast Response with tag Tx	Shows the number of AirGroup responses transmitted with meta-tag information.
Raw Response Tx	Shows the number of mDNS or DLNA responses transmitted.

Column	Description
Request with Tag Rx	Shows the number of AirGroup queries received with meta-tag information.
Unicast Response with tag Rx	Shows the number of AirGroup responses received with meta-tag information.
Raw Response Rx	Shows the number of mDNS or DLNA responses received.

show airgroup policy-entries

```
show airgroup policy-entries [mac {neighborhood <macaddr>}|<macaddr>]
```

Description

This command shows active AirGroup policies.

Parameter	Description
mac neighborhood <macaddr>	Shows AP neighborhood to discover the AirGroup server.
mac <macaddr>	Shows active AirGroup policies for the specified MAC address.

Example

The following example shows the active AirGroup policies:

```
(host) [mynode] #show airgroup policy-entries

AirGroup Device Policy Information
-----
Device          device-owner  shared location-id AP-name  shared
location-id AP-FQLN
-----
aa:aa:aa:aa:aa:aa  N/A
aa:bb:cc:dd:ee:ff  N/A          xyzzy

shared location-id AP-group  shared user-list  shared group-list  shared
role-list
-----
                                sy          saasa
                                test

CPPM-Req  CPPM-Resp  source  Auto-Associate  Neighborhood
-----  -
                                CLI          1 hop(s)
                                CLI          AP-Name      1 hop(s)

Num Policy Entries:2
```

The output of this command includes the following parameters:

Column	Description
Device	Shows the MAC address of the device.
device-owner	Shows the device owner information.
shared AP-name	Shows the shared AP name information.
shared AP-FQLN	Shows the shared AP FQLN information.
shared AP-group	Shows the shared AP group information.
shared users	Shows the shared user information.
shared groups	Shows the shared group information.
shared roles	Shows the shared roles information.
CPPM-Req	Shows the ClearPass Policy Manager requests.
CPPM-Resp	Shows the ClearPass Policy Manager responses.
source	Shows the source (CLI or ClearPass Policy Manager) of the policy.
Auto-associate	Shows the auto association information.
Neighborhood	Shows the neighborhood information.

The following example shows the AP neighborhood to discover the AirGroup server by using a specific MAC address:

```
(host) [mynode] #show airgroup policy-entries mac 00:1a:1e:aa:bb:cc

AirGroup Device Policy Information
-----
Device          device-owner  shared location-id AP-name  shared
location-id AP-FQLN
-----
00:1a:1e:aa:bb:cc  N/A

shared location-id AP-group  shared user-list  shared group-list  shared
role-list
-----
test

CPPM-Req  CPPM-Resp  source  Auto-Associate  Neighborhood
-----
CLI  1 hop(s)
```

```
Num Policy Entries:1
```

The output of this command includes the following parameters:

Column	Description
Device	Shows the MAC address of the device.
device-owner	Shows the device owner information.
shared AP-name	Shows the shared AP name information.
shared AP-FQLN	Shows the shared AP FQLN information.
shared AP-group	Shows the shared AP group information.
shared users	Shows the shared user information.
shared groups	Shows the shared group information.
shared roles	Shows the shared roles information.
CPPM-Req	Shows the ClearPass Policy Manager requests.
CPPM-Resp	Shows the ClearPass Policy Manager responses.
source	Shows the source (CLI or ClearPass Policy Manager) of the policy.
Auto-associate	Shows the auto association information.
Neighborhood	Shows the neighborhood information.

show airgroup query-result

```
show airgroup query-result {excluded}| {mac <server mac address>
```

Description

This command shows the list of AirGroup servers that are available and excluded for a client.

This command should be executed only after issuing the `airgroup send-query` command.

Parameter	Description
<code>excluded</code>	Shows the list of servers that are excluded for a client.
<code>mac <server mac address></code>	Shows the AirGroup server information of a specific MAC address.

Example

The following example displays the AirGroup query result:

```
(host) [mynode] #show airgroup query-result

Query result generated:
Timestamp :: 2022-08-09 21:08:55
Client :: 00:8e:9b:00:00:00
Service-id :: _airplay_tcp
AP Name :: APSim04_000_000
User name :: user1
User role :: authenticated
User group :: -
VLAN ID :: 50
```

CPPM State: Done - CPPM request done; Fail - CPPM Request failed; No policy - No Policy in Clearpass; NR - Not required; Req 1/2/3 - Request Attempt number; Global CPPM State -

Req 3 Flags: A - AP location; C - CPPM policy; D - Entry added with username based auto tag feature; M - MD location; R - Cluster location; S - AP Mcast server; U - Unknown location;

AirGroup Servers Included

MAC	IP	Type	Host Name	Service
---	--	----	-----	-----
00:8e:9b:00:00:07	50.1.0.9	mDNS,DLNA	sim_sta_000_007-APPLETVS	default-allowall

Command History

Release	Modification
ArubaOS 8.11.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode.

show airgroup servers

```
show airgroup servers
  debug
  dlna
  location <ap-group | ap-name | cluster | unknown>
  mac
  mdns
  username <username>
  verbose
```

Description

This command shows the list of AirGroup servers.

Parameter	Description
debug	Shows server debug information.
dlna	Shows the DLNA servers.
mac <macaddr>	Shows entries filtered on a specific MAC address of the server.
mdns	Shows the mDNS servers.
location	Shows the list of AirGroup servers based on the location.
ap-group	Shows the details of AirGroup servers mapped to an AP group,
ap-name	Shows the details of AirGroup servers mapped to an AP.
cluster	Shows the details of AirGroup servers mapped to a cluster.
unknown	Shows the list of servers for which the location is unknown.
username <username>	Shows the list of servers that share the same username
verbose	Shows the detailed statistics.

Example

The following example shows the list of AirGroup servers:

```

(host) [mynode] #show airgroup servers

AirGroup Servers
-----
MAC                IP                Type  Host Name        Service
---                --                ----  -
5c:aa:fd:52:5a:f8  10.16.124.224    DLNA  world_cricket    allowall
                    10.16.124.226    DLNA  world_cricket    DLNA Media
5c:aa:fd:52:5a:fa  10.16.124.226    DLNA  world_cricket    DLNA Media
                    10.16.126.16     DLNA  world_cricket    allowall
f0:4d:a2:83:74:a5  10.16.126.16     DLNA  world_cricket    DLNA Media
                    0.0.0.0           mDNS  world_cricket    allowall
11:11:11:11:11:11  0.0.0.0           mDNS  world_cricket    static
a0:02:dc:85:c2:98  10.16.124.181    DLNA  10-16-124-181    DIAL

VLAN  Wired/Wireless  Role      Group  Username  AP-Name
----  -
124   wireless        ipad      -
124   wireless        ipad      -
126   N/A
0     N/A
124   wireless        x86-role  -      arr

Num Servers: 5.

```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup server.
IP	Shows the IP address of the AirGroup server.
Type	Shows the type (DLNA/mDNS) of the AirGroup server.
Host Name	Shows the host name of the AirGroup server.
Service	Shows the service hosted by the AirGroup server.
VLAN	Shows the VLAN ID of the AirGroup server.
Wired/Wireless	Shows how (wired/wireless) the AirGroup server is connected. NOTE: The column displays Wired when the server is connected to an untrusted wired port. When the server is connected to a trusted wired port, the column displays N/A .
Role	Shows the user role of the AirGroup server.

Column	Description
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup server.
AP-name	Shows the AP name to which the AirGroup server is connected.

The following example shows the list of AirGroup servers hosting DLNA service:

```
(host) [mynode] #show airgroup servers dlna

AirGroup Servers
-----
MAC          IP           Type  Host Name      Service
---          --          ---  -
5c:aa:fd:52:5a:f8  10.16.124.224  DLNA
5c:aa:fd:52:5a:fa  10.16.124.226  DLNA
f0:4d:a2:83:74:a5  10.16.126.16   DLNA
a0:02:dc:85:c2:98  10.16.124.181  DLNA  10-16-124-181  DIAL

VLAN  Wired/Wireless  Role      Group  Username  AP-Name
----  -
124   wireless       ipad
124   wireless       ipad
126   N/A
124   wireless       x86-role
Num Servers: 4.
```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup server.
IP	Shows the IP address of the AirGroup server.
Type	Shows the type (DLNA/mDNS) of the AirGroup server.
Host Name	Shows the host name of the AirGroup server.
Service	Shows the service hosted by the AirGroup server.
VLAN	Shows the VLAN ID of the AirGroup server.

Column	Description
Wired/Wireless	Shows how (wired/wireless) the AirGroup server is connected. NOTE: The column displays Wired when the server is connected to an untrusted wired port. When the server is connected to a trusted wired port, the column displays N/A .
Role	Shows the user role of the AirGroup server.
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup server.
AP-name	Shows the AP name to which the AirGroup server is connected.

The following example shows the list of AirGroup servers hosting mDNS service:

```
(host) [mynode] #show airgroup servers mdns

AirGroup Servers
-----
MAC                IP                Type  Host Name      Service
---                --                ---  -
11:11:11:11:11:11  0.0.0.0          mDNS  world_cricket  static

VLAN  Wired/Wireless  Role    Group  Username  AP-Name
----  -
0     N/A
Num Servers: 1.
```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup server.
IP	Shows the IP address of the AirGroup server.
Type	Shows the type (DLNA/mDNS) of the AirGroup server.
Host Name	Shows the host name of the AirGroup server.
Service	Shows the service hosted by the AirGroup server.
VLAN	Shows the VLAN ID of the AirGroup server.
Wired/Wireless	Shows how (wired/wireless) the AirGroup server is connected.

Column	Description
	NOTE: The column displays Wired when the server is connected to an untrusted wired port. When the server is connected to a trusted wired port, the column displays N/A .
Role	Shows the user role of the AirGroup server.
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup server.
AP-name	Shows the AP name to which the AirGroup server is connected.

The following example shows the detailed statistics of the AirGroup servers:

```
(host) [mynode] #show airgroup servers verbose

AirGroup Servers
-----
MAC                IP                Type  Host Name      Service
---                --                ---  -
5c:aa:fd:52:5a:f8  10.16.124.224   DLNA  -              allowall
                                      DLNA Media

Num Servers: 5.
```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup server.
IP	Shows the IP address of the AirGroup server.
Type	Shows the type (DLNA/mDNS) of the AirGroup server.
Host Name	Shows the host name of the AirGroup server.
Service	Shows the service hosted by the AirGroup server.
Wired/Wireless	Shows how (wired/wireless) the AirGroup server is connected. NOTE: The column displays Wired when the server is connected to an untrusted wired port. When the server is connected to a trusted wired port, the column displays N/A .
VLAN	Shows the VLAN ID of the AirGroup server.
Role	Shows the user role of the AirGroup server.
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup server.
AP-name	Shows the AP name to which the AirGroup server is connected.
Rec-dropped	Shows the number of queries dropped from the AirGroup server.
Rec-filtered	Shows the number of queries filtered as a result of the policies.
Rec-responded	Shows the number of queries responded from the AirGroup server.
Last-query	Shows the time stamp of the last query received.
CPPM-Req	Shows the number of requests sent to the ClearPass Policy Manager server to populate the policy details for the given AirGroup server.
CPPM-Rsp	Shows the number of responses received from the ClearPass Policy Manager server for policy details of the given AirGroup server.
CoA	Shows the number of Change of Authorization (CoA) requests sent by ClearPass Policy Manager server indicating the registered device.

Column	Description
CPPM Dev-Added	Shows the last time stamp when ClearPass Policy Manager policy information was learned.
CPPM Dev-Deleted	Shows the last time stamp when this device entry was deleted from the ClearPass Policy Manager table.
Max PPM	Shows the maximum PPM.
Max PPM at	Shows when the maximum PPM was reached.
All IPs	Shows all IP addresses
controller IP	Shows IP address of other stand-alone controllers.

Command History

Release	Modification
ArubaOS 8.11.0.0	The following modifications were introduced: <ul style="list-style-type: none"> ■ The username parameter was introduced. ■ The flag, D was introduced in the output of the command to indicate that the servers share the same username.
ArubaOS 8.9.0.1	The <code>location</code> parameter was introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show airgroup status

```
show airgroup status
```

Description

This command shows the status of AirGroup.

Example

The following example shows the status of AirGroup:

```
(host) [mynode] #show airgroup status

AirGroup version: ver1

AirGroup Information
-----
Feature                Status
-----                -
MDNS                   Disabled
DLNA                   Enabled
Enforce Registration   Disabled
IPV6                   Enabled

AirGroup Service Information
-----
Service      Status
-----
remotemgmt   Disabled
DIAL         Enabled
AmazonTV     Enabled
DLNA Media   Enabled
test        Enabled
static       Enabled
combined     Enabled
DLNA Print   Disabled
allowall     Enabled
sharing      Disabled
chat        Disabled
Daniel      Enabled
itunes      Disabled
airplay     Enabled
airprint    Enabled
googlecast  Enabled
```

Starting from ArubaOS 8.11.0.0, the command displays whether the domain name has been included for username based policies:

```
(host) [mynode] #show airgroup status
```

```

Showing AirGroup info from /md
AirGroup Information
-----
Feature                Status
-----
AirGroup version      ver2
AirGroup mode         Centralized
AirGroup Profile      newestest
CPPM Profile          load-baance
Active domain         NA
Network Profile       default
MDNS                  Enabled

AirGroup Service Information
-----
Service                Status
-----
default-airprint      Enabled
default-dlna-media    Enabled
default-dial          Enabled

AirGroup Profile Network Profile
-----
Max no. of servers per query:      30
Max no. of servers in location:    100
Wired Server Expiry (min):         10
Wireless Server Expiry (min):      120
Include domain for username policy: False
MAC:0
OUI:0

```

The output of this command includes the following parameters:

Column	Description
Feature	Shows name of the AirGroup feature.
Status	Shows status of the AirGroup feature.
Service	Shows name of the AirGorup service.
Status	Shows status of the AirGroup service.
AirGroup Profile Network Profile	Shows the details of AirGroup Profile Network Profile

show airgroup tracebuf

```
show airgroup tracebuf [msgs [ip <ipaddr>]][mac <macaddr>]]|pps]
```

Description

This command shows the trace buffer.

Parameter	Description
msgs [ip <ipaddr>]	Shows the AirGroup trace buffer for the specified IP address.
msgs [mac <macaddr>]	Shows the AirGroup trace buffer for the specified MAC address.
pps	Shows the AirGroup packet arrival trace buffer.

Example

The following example shows the trace buffer:

```
(host) [mynode] #show airgroup tracebuf

Airgroup Client(s) Message Trace
-----
Client(MAC)  Client(IP)  Time  Event
-----
Airgroup Packet Arrival Message Trace
-----
Time          Event
-----
Jul  5 10:35:42  Total Packets 454, MDNS: 0, DLNA: 0, Servers: 5, Users 16,
CPU 0.10
Jul  5 10:20:41  Total Packets 286, MDNS: 0, DLNA: 0, Servers: 5, Users 17,
CPU 0.07
Jul  5 10:17:40  Total Packets 282, MDNS: 0, DLNA: 0, Servers: 5, Users 18,
CPU 0.07

CPU 0.08
Jul  4 11:29:11  Total Packets 190, MDNS: 0, DLNA: 0, Servers: 2, Users 3,
CPU 0.06
Jul  4 11:18:10  Total Packets 85, MDNS: 0, DLNA: 0, Servers: 1, Users 0,
CPU 0.03
Jul  4 11:17:10  Total Packets 6, MDNS: 0, DLNA: 0, Servers: 1, Users 0, CPU
0.00
Num Trace Entries:9
```

The output of this command includes the following parameters:

Column	Description
Client (MAC)	Shows the MAC address of the client.
Client (IP)	Shows the IP address of the client.
Time	Shows the time when the event occurred.
Event	Shows the details of the event.

Related Commands

show airgroup users

```
show airgroup users [mac|dlna|mdns|verbose]
```

Description

This command shows the AirGroup user table.

Parameter	Description
mac <macaddr>	Shows entries filtered on a specific MAC address of the server.
dlna	Shows the DLNA users.
mdns	Shows the mDNS users.
verbose	Shows detailed statistics.

Example

The following example shows the AirGroup users:

```
(host) [mynode] #show airgroup users

AirGroup Users
-----
MAC          IP          Type  Host Name  VLAN  Wired/Wireless  Role
Group  Username  AP-Name  -----  ----  -----
-----  -----  -----
b8:ca:3a:cb:cd:c4  10.16.126.18  DLNA          126  N/A
34:e6:d7:09:d6:41  10.16.126.25  mDNS          126  N/A
34:e6:d7:09:d7:9b  10.16.126.29  DLNA          126  N/A
f8:ca:b8:18:10:58  10.16.126.54  mDNS          126  N/A
Num Users: 4.
```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup user.
IP	Shows the IP address of the AirGroup user.
Type	Shows the type of the AirGroup device.

Column	Description
Host Name	Shows the host name of the AirGroup user.
VLAN	Shows the VLAN ID of the AirGroup user.
Wired/Wireless	Shows how the AirGroup user is connected.
Role	Shows the user role of the AirGroup user.
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup user.

The following example shows the dlna AirGroup users:

```
(host) [mynode] #show airgroup users dlna

AirGroup Users
-----
MAC          IP          Type  Host Name  VLAN  Wired/Wireless  Role
Group  Username  AP-Name
---      ---      ---
-----  -----  -----
b8:ca:3a:cb:cd:c4  10.16.126.18  DLNA          126  N/A
34:e6:d7:09:d7:9b  10.16.126.29  DLNA          126  N/A
Num Users: 2.
```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup user.
IP	Shows the IP address of the AirGroup user.
Type	Shows the type of the AirGroup device.
Host Name	Shows the host name of the AirGroup user.
VLAN	Shows the VLAN ID of the AirGroup user.
Wired/Wireless	Shows how the AirGroup user is connected.
Role	Shows the user role of the AirGroup user.
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup user.

The following example shows the mDNS AirGroup users:

```
(host) [mynode] #show airgroup users mdns

AirGroup Users
-----
MAC          IP          Type  Host Name  VLAN  Wired/Wireless  Role
Group  Username  AP-Name
-----  -----  -----  -----  -----  -----  -----
34:e6:d7:09:d6:41  10.16.126.25  mDNS          126  N/A
f8:ca:b8:18:10:58  10.16.126.54  mDNS          126  N/A
Num Users: 2.
```

The output of this command includes the following parameters:

Column	Description
MAC	Shows the MAC address of the AirGroup user.
IP	Shows the IP address of the AirGroup user.
Type	Shows the type of the AirGroup device.
Host Name	Shows the host name of the AirGroup user.
VLAN	Shows the VLAN ID of the AirGroup user.
Wired/Wireless	Shows how the AirGroup user is connected.
Role	Shows the user role of the AirGroup user.
Group	Shows the group of the AirGroup user.
Username	Shows the user name of the AirGroup user.

show airgroup vlan

show airgroup vlan

Description

This command shows a list of AirGroup VLANs with certain associated details such as VLAN ID, server status, and user status.

Example

The following example shows a list of AirGroup VLANs:

```
(host) [mynode] #show airgroup vlan

VLAN Table
-----
Vlan-Id  Server Status  User Status
-----
1         Allowed        Allowed
9         Allowed        Allowed
50        Allowed        Allowed
124       Allowed        Allowed
default  N/A            N/A
Num Vlans:5
```

The output of this command includes the following parameters:

Column	Description
Vlan-Id	Shows the VLAN ID.
Server Status	Shows the status of AirGroup server.
User Status	Shows the status of AirGroup user.

Related Commands

Command	Description
airgroup	This command configures AirGroup settings.

show airgroupprofile

```
show airgroupprofile
  activate
  ccpm <name>
  domain <name>
  ipv6 <name>
  network default
  service <service-name>
  <profile-name>
```

Description

This command shows the AirGroup profile settings.

Parameter	Description
activate	Shows the active AirGroup profile.
ccpm <name>	Shows the AirGroup ClearPass Policy Manager profile.
domain <name>	Shows the AirGroup domain profile.
ipv6 <name>	Shows the AirGroup IPv6 profile.
network default Enter MAC-Address or MAC-OUI to be blacklisted/denylisted Configure max allowed IP per device. Default: 4 Configure max allowed tokens/cache per device (Default: 40) 40	Shows the default AirGroup network profile. The Enter MAC-Address or MAC-OUI to be blacklisted /denylisted lists any blacklisted /denylisted MAC address. The Configure max allowed IP per device. Default: 4 lists the maximum number of IP addresses.

Parameter	Description
	The Configure max allowed tokens/cache per device (Default: 40) lists the maximum number of cache entries.
<code>service <service-name></code>	Shows the AirGroup service profile.
<code><profile-name></code>	Shows the AirGroup profile settings ClearPass Policy Manager details. <ul style="list-style-type: none"> ■ entries: Shows information for devices registered in ClearPass Policy Manager. ■ server-group: Shows ClearPass Policy Manager server group information.

Example

The following example shows the current status of the AirGroup service default-airplay:

```
(host) [mynode] #show airgroupprofile service default-airplay

Airgroup Service Profile "default-airplay"
-----
Parameter          Value
-----
Service Id         _airplay._tcp
Service Id         _appletv-v2._tcp
Service Id         _raop._tcp
Service Description AirPlay
The following example shows the current status of the AirGroup default
network profile:
(host) [mynode] #show airgroupprofile network default
```

```

Network profile "default" (Predefined (changed))
-----
Parameter                                     Value
-----
Enter MAC-Address or MAC-OUI to be blacklisted/denylisted      N/A
Configure max allowed IP per device. Default: 4                 4
Configure max allowed tokens/cache per device (Default: 40)    40

```

Related Commands

Command	Description

Command History

Release	Modification
ArubaOS 8.7.0.0	The <code>network default</code> parameter was updated to include the following sub-parameters: <ul style="list-style-type: none"> ■ Enter MAC-Address or MAC-OUI to be blacklisted ■ Configure max allowed IP per device. Default: 4 ■ Configure max allowed tokens/cache per device (Default: 40)
ArubaOS 8.6.0.3	The <code>network default</code> parameter was introduced.
ArubaOS 8.2.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airgroupservice

show airgroupservice [dlna|mdns|verbose]

Description

This command shows information about AirGroup services.

Parameter	Description
dlna	Shows the DLNA services.
mdns	Shows the mDNS services.
verbose	Shows additional information of services.

Example

The following example shows the information of AirGroup DLNA services:

```
(host) [mynode] #show airgroupservice dlna

The output of this command includes the following parameters:

Column	Description
Service	Shows the name of the AirGroup DLNA service.
status	Shows the status of the AirGroup DLNA service.
service ID	Shows the AirGroup DLNA service ID.
Description	Shows the description of the AirGroup DLNA service.

Related Commands

Command	Description
airgroup	This command configures AirGroup settings.
airgroupprofile	This command configures an AirGroup profile.
show airtgroup	This command shows the global AirGroup settings.
show airtgroupprofile	This command shows the AirGroup profile settings.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show airmatch ap-partition

```
show airmatch ap-partition status detail <cluster-name>
```

Description

This command displays information about the partition of APs for cluster manager.

Syntax

Parameter	Description
status	Displays AP partition status.
detail	Displays details of AP partition.

Example

The following command displays information about the AirMatch debug data of an AP,

```
(host7) [mynode] #show airmatch ap-partition status detail
```

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.6.0.0	The following output parameters were added for AP-555 access points: <ul style="list-style-type: none"> ■ AP in Tri-Radio Mode ■ AP Tri-Radio Mode Last UpdTime
ArubaOS 8.3.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airmatch debug advanced db-size

show airmatch debug advanced db-size

Description

This command displays database statistics and database collection statistics.

Examples

The example below indicates the AirMatch statistics related to the APs:

```
(host)#show airmatch debug advanced db-size

AirMatch DB Statistics
-----
Number of Collections:      24
DB size (in MB):           0

AirMatch DB Collection Statistics
-----
Collection                  Number of Documents      Storage Size (Bytes)
-----
action_proto                0                          0
amon_stat                   2                          840

show airmatch debug advanced stat

```
show airmatch debug advanced stat
  ap
  channel
  deployment
  eirp
  event
  nbr
  radio
```

Description

This command displays detailed statistics about the APs or radios on a Mobility Conductor.

Parameter	Description
ap	Statistics related to the APs
channel	Statistics related to channel and channel bandwidth assignment
deployment	Statistics related to channel and EIRP deployment
eirp	Statistics related to the EIRP assignment
event	Statistics related to RF events
nbr	Statistics related to radio neighbors
radio	Statistics related to radios

Examples

The example below indicates the AirMatch statistics related to the APs:

```
(host)#show airmatch debug advanced stat ap

show airmatch debug amon-stat

show airmatch debug amon-stat

Description

Display statistics for AMON messages sent from APs to the Mobility Conductor. Each AP in a Mobility Conductor deployment measures its RF environment and then sends the managed device AMON messages about the radio feasibility based on that AP's hardware capability, radio and regulatory domain, and RF neighbors. The managed device forwards these messages to the Mobility Conductor, and the Mobility Conductor adds this information to a database, computes an optimal solution, and deploys the latest RF plan by sending updated settings to the APs. Run the `show airmatch debug amon-stat` to view details about these AMON messages.

Example

```
(ALPHA-SC) [mm] (config) #show airmatch debug amon-stat

```

The output of this command includes the following parameters:

Column	Description
Last Update Time	Time the last AMON message information was sent to Mobility Conductor
Number of Packets	Total number of AMON packets sent to Mobility Conductor since the AMON process started. This counter resets when Mobility Conductor reboots.
Number of Bytes	Total number of AMON bytes sent to Mobility Conductor since the AMON process started. This counter resets when Mobility Conductor reboots.
Number of Messages	Total number of AMON packets sent to Mobility Conductor since the AMON process started. This counter resets when Mobility Conductor reboots.
ID	The ID number of the AMON message type. ArubaOS 8.0 supports AMON messages with the message ID of 42 .
Fields	Number of fields in the AMON message. AMON messages with the message ID of 42 include two fields.
Size	Total number of bytes sent for the AMON message ID.
Msgs	Total number of messages sent for that AMON message ID.
Bytes	Total number of bytes sent for that AMON message ID.
Sequence #	For Internal use only
Lost	Number of lost messages.
%	Percentage of lost messages.

show airmatch debug configs

```
show airmatch debug configs
```

Description

This command displays the advanced configuration settings in the AirMatch profile. The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-` output modifier helps you redirect the command output.

Example

The following command displays the configuration settings.

```
(host)[mm] #show airmatch debug configs
Field                               Value
----                               -

Column	Description
Mac	MAC address of the AP radio
Updated On	The last time the AP radio's feasibility information was updated in the Mobility Conductor database
Current Opmode	Current operation mode
HW Supported Opmodes	Supported operation modes
Configured Opmodes	Configured operation modes
Feasible Opmodes	Feasible operation modes
Chan 20MHz	List of feasible channels in 20 MHz bandwidth
Chan 40MHz	List of feasible channels in 40 MHz bandwidth
Chan 80MHz	List of feasible channels in 80 MHz bandwidth
Chan 160MHz	List of feasible channels in 160 MHz bandwidth
Bandwidth	List of feasible channel bandwidths
Config BW range(MHz)	List of configured channel bandwidths
Hardware BW range(MHz)	List of channel bandwidths supported by the hardware
Eirp Range Chan 20MHz	Range of EIRPs supported for each channel in a 20 MHz channel bandwidth
Eirp Range Chan 40MHz	Range of EIRPs supported for each channel in a 40 MHz channel bandwidth

Column	Description
Eirp Range Chan 80MHz	Range of EIRPs supported for each channel in a 80 MHz channel bandwidth
Eirp Range Chan 160MHz	Range of EIRPs supported for each channel in a 160 MHz channel bandwidth
EIRP (dBm)	Current supported EIRP range, in dBm.
Config EIRP range (dBm)	Configurable EIRP range, in dBm
Hardware EIRP range (dBm)	Hardware EIRP range, in dBm
EIRP Offset (dB)	Offset of the EIRP added to the computed EIRP (in dB)
Band	Operational Band, in GHz
Band Range	Current band range
Update Reason	Reason for previous feasibility update, such as a periodic update, radar detection, changes to a regulatory domain profile, or a radio band change for an AP radio that can operate in flex-radio mode. An AP radio that supports flex mode can operate as a single radio in the 2.4 GHz band, a single radio in the 5 GHz band, or as two radios, operating separately in the 2.4 GHz and 5 GHz bands.

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile .
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.6.0.0	The output will display the tri-radio mode values for AP-555 access points.
ArubaOS 8.3.0.0	The following parameters were introduced in the command output:

Release	Modification
	<ul style="list-style-type: none"> ■ Current Opmode ■ HW Supported Opmodes ■ Configured Opmodes ■ Feasible Opmodes ■ Eirp Range Chan 20MHz ■ Eirp Range Chan 40MHz ■ Eirp Range Chan 80MHz ■ Eirp Range Chan 160MHz
ArubaOS 8.2.0.0	The output in the EIRP field can display EIRP values in .1 dBm increments, and the Update Reason field can show if an AirMatch update was made due to a radio band change by an AP radio that supports both 1x1 dual radio mode and 2x2 single radio mode.
ArubaOS 8.0.0.0	Command introduced.

show airmatch debug history

```
show airmatch debug history
  ap-name <name>
  mac <mac>
```

Description

This command displays a history of AirMatch updates to an AP radio's channel, bandwidth, EIRP or mode.

Parameter	Description
ap-name <name>	Name of an AP for which you want to view AirMatch history data
mac <mac>	MAC address of an AP's radio (BSSID address) for which you want to view AirMatch history data

Example

```
(host)[mm] #show airmatch debug history ap-name West-2-155

```

The output of this command includes the following parameters:

Column	Description
Time of Change	Timestamp showing when the change was made.
Chan	Previous and current channel assignments .
Bandwidth	Previous and current bandwidth assignments.
EIRP (dBm)	Previous and current EIRP levels.
Mode	Previous and current AP mode. Supported modes are AP and APM (Air Monitor).
Source	Source of the confirmation changes. AP changes made as a result of AirMatch calculations appear with the source type of "solver".

Related Commands

The output of this command includes the following parameters:

Column	Description
Nbr Mac	MAC address of the neighbor AP.
Is Friend	Indicates whether the neighbor AP is associated to the same Mobility Conductor as the reporting AP.
Path Loss (dB)	Path loss between the neighbor AP and reporting AP, in dB.
Channel	Radio channel used by the neighbor AP.
Last Update	Date and time the reporting AP last received updated information from the neighbor AP.
AP Name	Name of the neighbor AP. The AP name will only appear if the neighbor AP is managed by the same Mobility Conductor as the reporting AP.

Related Commands

Command	Description

show airmatch debug optimization

```
show airmatch debug optimization
  advanced partition
  [last | <seq>]
  [sort-by {ap-name | band | bandwidth | channel | eirp | rf-domain-id}]
  [descending]
```

Description

This command displays a list of RF debug optimizations performed by AirMatch.

Parameter	Description
advanced partition	Advanced partition information.
last	Last debug optimization.
<seq>	Optimization sequence number.
sort-by	Sorts the results in ascending order and on a per-band basis. Use this after specifying an optimization number or last as the value.
ap-name	Sorts results based on the AP name. Ascending order
band	Sorts results based on the band. 2 GHz, 5 GHz Ascending order
bandwidth	Sorts results based on the bandwidth. Ascending order
channel	Sorts results based on the channel. Ascending order
eirp	Sorts results based on the EIRP. Ascending order
rf-domain-id	Sorts results based on the RF domain ID. Ascending order
descending	Sort results in descending order.

Example

The following example shows a detailed summary of the RF debug optimization:

```
(host) [mm] #show airmatch debug optimization
```

Seq	Time	APs	[5GHz] Radios	Cost	Conflict

    nbr-ap-name
    nbr-bssid
  bssid <radio-bssid>
```

Description

This command displays information about the recent AirMatch debug path loss.

Parameter	Description
ap-name <name>	Name of an AP for which you want to view AirMatch debug path loss history.
nbr-radio	Specify one of the following neighbor radio details: <ul style="list-style-type: none">▪ nbr-ap-name <nbr-ap-name>: Specify neighbor AP name.▪ nbr-bssid <nbr-bssid>: Specify neighbor radio BSS ID.
bssid <radio-bssid>	Shows the debug path loss history for a specific BSSID.

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.3.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airmatch debug populate-db

```
show airmatch debug populate-db
  status
    all
    ap-info
    feasibility
```

Description

This command displays information about the database population of the collection.

Syntax

Parameter	Description
status	Displays database population status information.
all	Displays status of all required collections in database.
ap-info	Displays status of ap-info collection population.
feasibility	Displays status of feasibility collection population.

Example

The following command displays information about the AirMatch debug data of an AP,

```
(host7) [mynode] #show airmatch debug populate-db status
```

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

show airmatch debug reporting-radio

```
show airmatch debug reporting-radio
  ap-name <name>
  mac <mac>
  list-all
```

Description

Displays details for an AP radio reporting AirMatch data to a Mobility Conductor.

Parameter	Description
ap-name <name>	Name of an AP for which you want to view AirMatch radio data.
mac <mac>	MAC address an AP for which you want to view AirMatch radio data.
list-all	Lists all the radios in the database.

Example

```
(host) [mm] #show airmatch debug reporting-radio ap-name ssa-155

```

The output of this command includes the following parameters:

Column	Description
Band	Radio band used by the AP
AP Ethernet MAC	MAC address of the Ethernet interface
Radio MAC	MAC address of the AP radio
AP Name	Name of the AP
AP Model	AP model type
LMS IP	IP address of the controller to which the AP is associated
Last Update	Timestamp showing the date and time the AP last sent an update to Mobility Conductor
Channel	Channel used by the AP radio
Bandwidth	Bandwidth used by the AP radio
Channel Reason	Reason why the channel was modified
Channel Update Time	Timestamp showing the date and time that the channel was updated
EIRP	Radio EIRP, in dBm.
EIRP Reason	Reason why the EIRP setting was modified
EIRP Update Time	Timestamp showing the date and time that the EIRP setting was updated
Is Active	Indicates if the AP is active on the network.
Is Static Chan	Indicates if the AP has been assigned to a static channel
Is Static EIRP	Indicates if the AP has been assigned to a static EIRP level
Is Static CSR	Indicates if the AP has been assigned to a static Cell Size Reduction (CSR) value. Cell Size Reduction settings control Rx sensitivity for the AP. When it is set to a specific value, the radio will not receive any frames with SNR/RSSI below this configured value.

Related Commands

Command	Description

show airmatch debug schedule

```
show airmatch debug schedule
  job-list
  switch-info
```

Description

This command displays details about deployment schedules when AirMatch updates are sent to the APs.

Parameter	Description
job-list	The scheduled deployment time and duration details of APs as per the timezone.
switch-info	The timezone and deploy configured on the switch.

Example

```
(host) [mynode] #show airmatch debug schedule switch-info

# Generated: 2020-05-16_22:56:44   MM deploy time: 5:00   MM time zone: IST-5:30

show airmatch debug solver feasibility

```
show airmatch debug solver feasibility
  optimization <seq> {ap-name <ap-name> | bssid <bssid>}
```

Description

Displays the feasibility information used by AirMatch Solver for a particular AP or MAC address during optimization. The optional output modifiers | begin, | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
optimization	Displays the optimization history.
<seq>	Specify a sequence number to view details for a specific AirMatch solution.
ap-name <name>	Specify the name of an AP with the <ap-name> parameter to view AirMatch solver for the radios on that AP.
bssid <bssid>	Show data for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address.

Example

```
(host) [mm] #show airmatch debug solver feasibility optimization 284 ap-name

show airmatch event

```
show airmatch event [{all-events|noise|radar|priority-events} [all-aps | ap-name  
<ap-name> | bssid <bssid>]] <yyyy-mm-dd>
```

Description

Displays radar and noise event information for a specific AP or all APs. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
all-events noise priority-events radar	Display one of the following event information of the APs in the database: <ul style="list-style-type: none">▪ all-events: Radar and Noise events in the database (sorted by latest).▪ noise: Noise event list.▪ priority-events: All priority rf-events in database.▪ radar: Radar event list.
all-aps	Display list of all the APs in the database.
ap-name <ap-name>	Specify the name of an AP to display its radar and noise events.
bssid <bssid>	Show data for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address.
<yyyy-mm-dd>	Show date in YYYY-MM-DD format.

Example

The following example displays the noise and radar event information for all APs in the database.

```
(host) [mynode] #show airmatch event all-events all-aps
```

Command Information

Platforms	Licensing	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show airmatch tech-support

```
show airmatch tech-support
  ap-name <name>
  mac <mac>
```

Description

This command collects the output for the AP or the radio for further support or engineering analysis. You can add a file name at the end of this command to capture the output to the flash.

Parameter	Description
ap-name <name>	Name of an AP for which you want to view AirMatch technical support data.
mac <mac>	MAC ID of an AP for which you want to view AirMatch technical support data.

Example

The following example displays the output of the `show airmatch tech-support mac ac:a3:1e:59:b4:c0` command:

```
(host) [mynode] #show airmatch tech-support mac ac:a3:1e:59:b4:c0

airmatch profile	This command configures the AirMatch profile.

Command	Description
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.2.1.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airmatch network-tech-support

```
show airmatch network-tech-support
  ap-name <name>
  band <bandname> {2.4GHz|5GHz} <rf-domain>
  mac <mac>
```

Description

This command collects the output for all the radios that are in the same partition for a specified radio AP name. This command also lists and describes the AP radios that are handled further. Run this command to collect the output for further support or engineering analysis. You can add a file name at the end of this command to capture the output to the flash.

Parameter	Description
ap-name <name>	Name of an AP for which you want to view AirMatch network support data
band	Radio type based on which the AP operates 2.4GHz to 5GHz
mac <mac>	MAC address an AP for which you want to view AirMatch network support data

Example

The following example displays a partial output of the `show airmatch network-tech-support ap-name F-16-a-QCA` command:

```
(host) [mynode]#show airmatch network-tech-support ap-name F-16-a-QCA
```

```

show airmatch optimization

show airmatch optimization <seq>

Description

This command displays the list of recent RF optimization jobs performed by AirMatch.

Parameter	Description
<seq>	Specify a sequence number to view details for a specific AirMatch solution.

Example

The following example shows the history AirMatch solutions for 5 GHz and 2 GHz radios.

```
(host) *[mynode] #show airmatch optimization
Seq Time           APs [5GHz] Radios Cost Conflict Deploy [2GHz]
Radios Cost Conflict Deploy Type
-----
#14 20161025_05:04:53 3          3 2.2 0.0 No
    0 0.0 0.0 No Scheduled
#13 20161024_05:04:53 3          3 2.2 0.0 No
    0 0.0 0.0 No Scheduled
#12 20161023_05:04:50 3          3 2.2 0.0 No
    0 0.0 0.0 No Scheduled
#11 20161022_05:04:50 3          3 2.2 0.0 Yes
    0 0.0 0.0 No Scheduled
#10 20161020_10:12:59 2          2 2.0 0.0 Yes
    0 0.0 0.0 Yes On-demand
#9  20161020_09:20:23 2          2 2.0 0.0 Yes
    0 0.0 0.0 Yes Quick
#8  20161020_09:19:27 2          2 2.0 0.0 Yes
    0 0.0 0.0 Yes On-demand
```

The output of the `show airmatch optimization` command includes the following parameters:

Column	Description
Seq	Sequence number of the solution. The solution with the highest sequence number is the most recent.
Time	Timestamp showing the date and time AirMatch sent the solution update

Column	Description
APs	Number of APs updated with the new solution
Radios	Number of 5 Ghz or 2 Ghz AP radios updated with the new solution.
Capacity	Capacity is an internal metric to track the quality of a solution. The higher the capacity, the better the solution.
Cost	Cost is an internal metric to track the cost of a solution or a network state. The lower the cost, the better the solution. It is a measure of the overall quality of the solution or the network state.
Conflict	Conflict is an internal metric to track the quality of a solution. The lower the conflict, the better the solution.
Deploy	This column displays a status of Yes if the improvement in the radio band met or exceeded the threshold for deployment. If this column displays a status of No , the solution was below the quality threshold and was not deployed.

To see the detail of channel and EIRP plan for all the radios in the network, append the solution sequence number in the same command.

```
(host) [mm/mynode] #show airmatch optimization 14
# 20161025_05:04:53      Scheduled
# 5GHz   capacity/network cost/solution cost/improvement: 11.0/2.2/2.2/0.0%
# 2.4GHz capacity/network cost/solution cost/improvement: 0.0/0.0/0.0/0.0%
# Band Radio              Mode Chan  CBW    EIRP (dBm)  APName
-----
5GHz 84:d4:7e:d2:10:90 AP    36*   160*     5*  ap315-1
5GHz 9c:1c:12:88:6c:70 AP    157i   40i    12.  ard4
5GHz 18:64:72:7e:4d:90 AP    149*   20*     5*  x4p3
[*] regarded frozen | [.] no change | [i] channel ignored because
insufficient quality increase
```

A radio is regarded frozen if any of the following are true:

- The CLI command `airmatch ap freeze` command has been used to configure and freeze radio settings
- The radio's regulatory domain profile leads to a single feasible channel by allowing only single valid channel, channel pair, or channel group.
- Neighboring radar and/or channel noise makes only a single channel feasible.

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.1.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airmatch profile

```
show airmatch profile
```

Description

This command displays the configuration settings in the AirMatch profile.

Example

In this example, the output has been divided into multiple sections to better fit on the pages of this document. In the actual CLI, the output appears in a single, long table.

```
(host)[mm] #show airmatch profile
AirMatch profile (Predefined (changed))
-----
Parameter          Value
-----
schedule           Enabled
deploy-hour        5 o'clock
quality-threshold  15 percent
```

The output of this command includes the following parameters:

Column	Description
Schedule	Indicates if AirMatch scheduled updates are enabled. If the AirMatch updates are changed from the default enabled setting to disabled , the Mobility Conductor continues to receive RF updates from the APs, but no channel and EIRP changes are executed by the Mobility Conductor at the scheduled time.
deploy-hour <0-23>	Specify a number from 0-23 to select the hour during which AirMatch updates are sent to the APs (in 24-hour format).
eirp-offset	Manually adjust EIRP levels selected by the AirMatch algorithm by specifying a value from -6 to 6 dBm
quality-threshold	The <code>quality-threshold</code> parameter represents the percentage of channel quality improvement that will trigger an AirMatch RF update. If a proposed channel change does not produce an improvement that meets or exceeds this threshold, AirMatch will not trigger a channel change.

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.1.0.0	The <code>eirp-offset</code> parameter is deprecated. EIRP offset values can now be configured for AP groups via the rf dot11a-radio-profile and rf dot11g-radio-profile commands.
ArubaOS 8.0.1.0	The <code>quality-threshold</code> parameter is introduced.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airmatch solution

```
show airmatch solution
  ap-name <ap-name>
  band <band>
  list-all
  mac <mac-addr>
  switch-ip
```

Description

This command displays history of AirMatch solution updates.

Parameter	Description
ap-name <ap-name>	Specify the name of an AP with the <ap-name> parameter to view AirMatch solutions for the radios on that AP.
band <band>	Specify the radio band for an AP as either 2 GHz, 5 GHz, or 6 GHz to view AirMatch solutions for that radio .
list-all	Show AirMatch solutions for all devices.
mac <mac-addr>	Show AirMatch solutions for a specific AP radio by entering the MAC address of the radio.
switch-ip <switch-ip>	Specify the IP address of the switch to view AirMatch solutions for that switch.

Example

The following example shows the history of AirMatch solutions.

```
(RagSC) ^[mynode] #show airmatch solution list-all

# Band Radio              Chan/Opt#    CBW      EIRP (dBm) /Opt# Client Band

The output of the **show airmatch solution** command includes the following parameters:

Column	Description
Band	Frequency band used by the radio
Radio	MAC address of an AP radio
Chan/Opt#	Channel from optimization Opt #, and the new optimization sequence ID applied by the solution. If no change was made, the Opt# column displays the value "NA".
CBW	Channel bandwidth used by the radio.
EIRP/Opt#	EIRP from optimization Opt #, and the optimization sequence ID applied by the solution. If no change was made, the Opt# column displays the value "NA".
Client Pref	Client preference from one of the following: <ul style="list-style-type: none"> ■ [p] HE Preferred ■ [n] Non-HE Preferred ■ [a] Allow-All
Band Pref	Band preference from one of the following: <ul style="list-style-type: none"> ■ [L] 5GHz-Lower ■ [U] 5GHz-Upper ■ [F] 5GHz-Full
AP_name	Name of the AP.

Related Commands

Command	Description
airmatch profile	This command configures the AirMatch profile.
airmatch ap	A radio set with the <code>airmatch ap freeze</code> command uses a static radio configuration until those settings get explicitly canceled with the <code>airmatch ap unfreeze</code> command.

Command History

Release	Modification
ArubaOS 8.6.0.0	The output for AP-555 access points will display details of Radio 2.
ArubaOS 8.1.0.0	The output of this command has been modified to include channel and EIRP information. The information that appeared in the output of this command in previous versions of ArubaOS now appear in the command show airmatch optimization .
ArubaOS 8.0.1.0	The output of this command is updated to include the following parameters for each radio band: <ul style="list-style-type: none"> ■ capacity ■ network cost ■ solution cost ■ improvement data
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show airslice

```
show airslice-profile <name>
show airslice-visibility
  client [table | <mac> ]
  debug counters
  record-limit
```

Description

This command displays the details of Air Slice profile.

Parameter	Description
airslice-profile <name>	Displays the Air Slice profile configuration details.
airslice-visibility	Displays the details of applications.
client table	Displays the details of applications used by clients.
client <mac>	Displays the details of applications used by a specific client.
debug counters	Copies data from another Air Slice profile.
no	Displays the debug counters of AirSlice visibility.
record-limit	Displays the configured record limit for clients.

Example

The following command displays the configured record limit of an Air Slice profile:

```
(host) [mynode] #show airslice-visibility record-limit
                 airslice-visibility record-limit :100
```

Command History

Release	Modification
ArubaOS 8.7.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
Air Slice is supported on all 802.11ax APs. However, Air Slice is supported only on 5 GHz radio and not on 6 GHz radio for 630 Series access points.	Base operating system.	Config and Enable mode on Mobility Conductor.

show ale-configuration

```
show ale-configuration
```

Description

This command displays ALE configuration on the Mobility Conductor.

Example

```
To display the ALE configuration:  
(host) [mynode] (config) #show ale-configuration  
  
Anonymization: false  
ALE Server-1: none  
ALE Server-2: none  
ALE Server-3: none  
ALE Server-4: none  
ALE Server-5: none  
nbapi_publish: true  
ale_sta_assoc: false
```

Related Command

Command	Description
ale-configuration	Enable ALE configuration and its parameters on the Mobility Conductor.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

show allowed-address-list

```
show allowed-address-list
  all
  ipv4
  ipv6
```

Description

This command displays the list of allowed IPv4 or IPv6 addresses that are exempted.

Parameter	Description
all	This parameter displays all the IP addresses in the allowed address list.
ipv4	This parameter displays the IPv4 addresses in the allowed address list.
ipv6	This parameter displays the IPv6 addresses in the allowed address list.

Related Commands

Command	Description
allowed-address-list	This command configures addresses exempted when the deny-inter-user-bridging is enabled.
no allowed-address-list	This command is used to remove the IP addresses that were added using allowed-address-list command.

Command History

Release	Modification
ArubaOS 8.8.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor and Managed Device.

show amon msg-buffer-size

```
show amon msg-buffer-size
```

Description

This command displays the size of AMON packets on the managed device.

Example

The following command displays size of AMON packet:

```
(host) [mynode] #show amon msg-buffer-size
amon msg-buffer-size :1264
```

Related Commands

Command	Description
amon msg-buffer-size	Modifies the size of AMON packets on the managed device.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platform	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

show amon-receiver

```
show amon-receiver [[dest-stats] | [dest-stats-all] | [dest-stats-inst-0] | [dest-  
stats-inst-1] | [dest-stats-inst-2] | [dest-stats-inst-3] | [dest-stats-inst-4] |

[parameter] | [set-debug-level-dest] | [src-stats-all] | [stats-counters] | [stats-  
counters-all]]
```

Description

This command displays AMON receiver information.

Parameter	Description
dest-stats	Shows destination statistics
dest-stats-all	Shows all destination statistics
dest-stats-inst-0	Shows destination statistics instance 0
dest-stats-inst-1	Shows destination statistics instance 1
dest-stats-inst-2	Shows destination statistics instance 2
dest-stats-inst-3	Shows destination statistics instance 3
dest-stats-inst-4	Shows destination statistics instance 4
dest-stats-inst-5	Shows destination statistics instance 5
dest-stats-inst-6	Shows destination statistics instance 6
dest-stats-inst-7	Shows destination statistics instance 7
dest-table	Shows destination table
error-counters	Shows error counters
error-counters-all	Show all error counters
interest-table	Show interest table
list-details	Show list details
parameter	Shows parameter String
set-debug-level-dest	Shows the set debug level for destination
src-stats-all	Shows all source statistics

Parameter	Description
stats-counters	Shows stats counters
stats-counters-all	Shows all stats counters

Example

The following command displays AMON receiver information for destination statistics instance 0:

```
(host) [mynode] #show amon-receiver dest-stats-inst-0

Description

This command displays AMON sender information. This command must be run on the managed device.

Parameter	Description
bundle counters	Shows the number of messages, records, and bytes in a bundle
bundle parameters	Shows the parameters that are in a bundle
cdt message-type <msgtype>	shows the column descriptor table for the specified AMON message number
dest-stats-all	Shows all destination statistics

Parameter	Description
dest-stats-all-all	Shows all destination statistics including entries with zero messages
dest-stats-inst-0	Shows destination statistics instance 0

Related Commands

Command	Description
<u>clear amon-sender</u>	This command displays AMON sender information.

Command History

Release	Description
ArubaOS 8.8.0.0	The output parameter, TAG of the <code>show amon-sender stats-counters-all</code> command gets incremented when there are RTLS frames from AMON receiver.
ArubaOS 8.4.0.0	The following parameters were added: <code>bundle counters</code> <code>bundle parameters</code> <code>cdt message-type</code>
ArubaOS 8.1.0.0	The following parameters were modified to accept IPv6 address: <code>dest-stats-all</code> <code>dest-stats-inst-0-7</code> <code>interest-table</code>
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config mode on Mobility Conductor.

show amon source-interface

show amon source-interface

Description

This command displays the source VLAN interface of AMON packets on the controller. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Example

The following command displays the source VLAN interface of the AMON feed:

```
(host) [mynode] #show amon source-interface  
amon source-interface:vlan 501
```

Related Commands

Command	Description
amon source-interface	Specifies the IPv4 address of the VLAN as the source IP address.

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Description

This command shows the access point settings. Click parameter links to view the corresponding show commands.

Parameter	Description
active	Shows APs currently registered or having clients terminating (in cluster) on this switch.
allowed-channels	Shows the set of allowed channels.
allowed-max-EIRP	Shows max EIRP setting per country per AP type.
analytics recommendations	Shows recommendations received from analytics engine.
antenna-status	Shows operational status of AP antennas.
ap-cert-mgr	Shows contents of /tmp/ap_cert_mgr_debug_log for an AP.
ap-group	Shows contents of AP's group.
ap-lacp-striping-ip	Shows profile to enable/disable AP LACP feature and to specify GRE striping IP to LMS IP mapping.
ap-name	Shows the list of AP names.
arm	Shows ARM Information.
assoc-throttle-counters	Shows counters related to association request throttling.
association	Shows Association table for an AP.
authorization-profile	Shows an AP Authorization profile.
blacklist-clients/denylist-clients	Shows list of clients that have been denied access.

Parameter	Description
<u>blacklist-protected/denylist-protected</u>	Shows all clients that are currently protected against further traffic steering for a period of time.
<u>blacklist-time/denylist-time</u>	Shows the amount of blacklist/denylist time of the STA when it is denylisted in between disconnection and user-timeout.
<u>ble-database</u>	Shows BLE APB information collected by BLE relay.
<u>ble-ibeacon-info</u>	Shows AP's BLE radio iBeacon parameters.
<u>bss-table</u>	Shows BSSIDs of all APs registered on this switch.
<u>bw-report</u>	Shows bandwidth allocation report for an AP.
<u>cellular</u>	Shows cellular information for an AP.
<u>client</u>	Shows wireless client specific information.
<u>cluster-tech-support</u>	Shows cluster information for an AP.
<u>config</u>	Shows AP configuration parameters.
<u>consolidated-provision</u>	Shows consolidated provision details of an AP.
<u>convert-download-log</u>	Shows conversion image downloading logs.
<u>convert-image-list</u>	Shows a list all available images for conversion.
<u>convert-setup-image-log</u>	Shows conversion setup image logs.
<u>convert-status</u>	Shows status of AP image conversion operation.
<u>convert-status-list</u>	Shows only the list of APs and their conversion statuses.
<u>convert-status-summary</u>	Shows status summary of conversion operation.
<u>crash-transfer</u>	Shows info for the AP crash transfer feature, which transfers AP coredump files to the controller flash memory if no dumpserver is configured.
<u>database</u>	Shows list of access points in the database.
<u>database-summary</u>	Shows a general summary of access point information for the controller.

Parameter	Description
<u>debug</u>	Shows debugging information of an AP.
<u>deploy-profile</u>	Shows the ap deploy-profile.
<u>details</u>	Shows details about an AP.
<u>dot1x</u>	Shows details about an 802.1X AP.
<u>enet-link-profile</u>	Shows an AP Ethernet Link profile.
<u>ssid</u>	Shows ESSID Information.
<u>est-status</u>	Shows contents of /tmp/est_status for an AP.
<u>general-profile</u>	Shows the AP general-profile.
<u>get-crash-dumps-status</u>	Shows get crash dumps status.
<u>global</u>	Shows AP's central database.
<u>greenap</u>	Shows details of AP supporting green mode.
<u>he-rates</u>	Shows high-efficiency rate information for a BSS.
<u>ht-rates</u>	Shows high-throughput rate information for a BSS.
<u>image</u>	Shows AP Image version.
<u>image-preload</u>	Shows status of AP image preload operation.
<u>ip</u>	Shows health check IP probe mode.
<u>license-usage</u>	Shows AP license usage information.
<u>lldp</u>	Shows details of Link-layer Discovery Protocol profile.
<u>load-balancing</u>	Shows all BSS where load balancing is enabled.
<u>mesh</u>	Shows all information for a mesh AP.
<u>mesh-accesslist-profile</u>	Shows a mesh access list profile.

Parameter	Description
<u>mesh-cluster-profile</u>	Shows a mesh cluster profile.
<u>mesh-ht-ssid-profile</u>	Shows a mesh High-throughput SSID profile.
<u>mesh-radio-profile</u>	Shows a mesh radio profile.
<u>mesh-recovery-profile</u>	Shows mesh recovery profile information.
<u>monitor</u>	Shows Air Monitor information.
<u>multizone-profile</u>	Shows an AP multizone profile.
<u>owe-tm-info</u>	Shows information about OWE Transition VAPs generated.
<u>packet-capture</u>	Shows packet capture commands.
<u>papi-err</u>	Shows PAPI error messages.
<u>port status</u>	Shows AP wired port information.
<u>power-mgmt-statistics</u>	Shows AP power status statistics.
<u>profile-usage</u>	Shows configuration profiles in use by an AP or a specific BSSID.
<u>provisioning</u>	Shows provisioning parameters currently used by an AP.
<u>provisioning-profile</u>	Shows provisioning profile of an AP.
<u>provisioning-rule</u>	Shows provisioning rule of an AP.
<u>provisioning-rules</u>	Shows provisioning rules of an AP.
<u>radio-database</u>	Shows radio information for APs that are visible to the controller.

Parameter	Description
<u>radio-summary</u>	Shows AP radios currently registered to the controller.
<u>regulatory</u>	Shows regulatory version used by APs.
<u>regulatory-domain-profile</u>	Shows regulatory domain profile of APs.
<u>remote</u>	Shows information from Remote AP.
<u>remote auth-trace-buf</u>	Shows authentication trace buffer on an AP.
<u>remote blacklist-clients/remote denylist-clients</u>	Shows all blacklisted/denylisted clients.
<u>remote blacklist-clients-driver/ remote denylist-cl</u>	Shows all clients blacklisted/denylisted in the driver.
<u>remote bss-table</u>	Shows BSSIDs of all APs registered on the managed device
<u>remote client status</u>	Shows association state of clients.
<u>remote counters</u>	Shows the numbers of message counters for Remote APs.
<u>remote debug anul-sta-entries</u>	Shows a list of VAPs and stations stored in the AP's datapath.
<u>remote debug association</u>	Shows the association table of the AP to identify the clients associated to each AP.
<u>remote debug association-failure</u>	Shows association failure information that can be used to troubleshoot problems on an AP.
<u>remote debug bss-config</u>	Shows the configuration for each BSSID of an AP.
<u>remote debug bucketmap-counters</u>	Shows bucket map counters.
<u>remote debug bucketmap datapath</u>	Shows bucket maps in AP datapath.
<u>remote debug bucketmap sapd</u>	Shows bucket map received from cluster by SAPD process.
<u>remote debug bucketmap stm</u>	Shows bucket map received from cluster by AP STM.
<u>remote debug client-mgmt-counters</u>	Shows the number of each type of message from the clients of an AP.

Parameter	Description
<u>remote debug flash-config</u>	Shows the remote AP configuration stored in flash memory.
<u>remote debug-mcast-forwarder</u>	Shows the Mcast forwarder status for the selected AP.
<u>remote debug mgmt-frames</u>	Shows traced 802.11 management frames for a remote AP.
<u>remote debug neighbor-cache</u>	Shows per-ESSID cached neighbor for a remote AP.
<u>remote debug nodelist history</u>	Shows the cluster node history for a remote AP.
<u>remote-debug-pkt</u>	Shows the packet debugging details of an AP.
<u>remote debug sapd</u>	Shows the state of cluster node in the SAPD process.
<u>remote debug redun-state history</u>	Shows the cluster node history for a remote AP.
<u>remote debug sta-msg-stats</u>	Shows AP-STM to STM message statistics.
<u>remote debug sta-msg-sta-down-entries</u>	Shows STA message for STA Down list.
<u>remote debug stale_sta</u>	Shows information for debugging an AP.
<u>remote debug stm cluster-nodestate</u>	Shows the cluster node state in AP.
<u>remote debug stm trace-files</u>	Shows STM trace files for an AP.
<u>remote debug uac-list</u>	Shows user anchor controller (UAC) list in AP datapath.
<u>remote essid</u>	Shows an ESSID summary for the Managed Device
<u>remote wmm-flow</u>	Shows the Wireless Multimedia (WMM) flows that are active on an AP connected to a Managed Device
<u>sapd-debug log</u>	Shows the SAPD debug log for an AP.
<u>snmp</u>	Shows SNMP tables of APs.
<u>spectrum</u>	Shows spectrum monitor information of APs.
<u>spectrum ap-list</u>	Shows spectrum data seen by an access point that has been converted to a spectrum monitor.

Parameter	Description
<u>spectrum channel-metrics</u>	Shows channel quality, availability, and utilization metrics as seen by a spectrum monitor.
<u>spectrum channel-summary</u>	Shows summary of the 802.11a or 802.11g channels seen by a spectrum monitor.
<u>spectrum client-list</u>	Shows details for clients seen by a specified spectrum monitor.
<u>spectrum debug</u>	Saves spectrum analysis channel information to a file on the spectrum monitor.
<u>spectrum debug fft</u>	Saves Fast Fourier Transform (FFT) power data to a file on the spectrum monitor.
<u>spectrum debug monitors</u>	Shows a detailed description of all spectrum monitors on the controller.
<u>spectrum debug status</u>	Shows detailed status and statistics for a spectrum monitor or hybrid AP.
<u>spectrum device-duty-cycle</u>	Shows the current duty cycle for devices on all channels.
<u>spectrum device-history</u>	Shows the history of the last 256 non- Wi-Fi devices.
<u>spectrum device-log</u>	Shows a time log of add and delete events for non- Wi-Fi devices.
<u>spectrum device-list</u>	Shows a device summary table and channel information for non- Wi-Fi devices currently seen by a spectrum monitor or hybrid AP radio.
<u>spectrum device-summary</u>	Shows the numbers of Wi-Fi and non- Wi-Fi device types on each channel monitored by a spectrum monitor or hybrid AP.
<u>spectrum interference-power</u>	Shows the interference power detected by a 802.11a or 802.11g radio on a spectrum monitor or hybrid AP.
<u>spectrum tech support</u>	Saves spectrum data for later analysis by technical support.
<u>spectrum-load-balancing</u>	Shows spectrum load balancing information for an AP.
<u>spectrum local-override</u>	Shows a list of AP radios currently converted to spectrum monitors through the spectrum local-override list.

Parameter	Description
<u>spectrum monitors</u>	Shows a list of APs terminating on the controller that are currently configured as spectrum monitors or hybrid APs.
<u>standby</u>	Shows standby APs currently registered on the controller.
<u>system-profile</u>	Shows an AP system profile.
<u>tech-support</u>	Shows all information for an AP that is used by Aruba technical support to diagnose a problem with an AP.
<u>uac-database</u>	Shows User Anchor Controller (UAC) AP database for a cluster.
<u>usb-acl-prof</u>	Shows an AP USB ACL profile.
<u>usb-device-mgmt</u>	Shows the USB devices managed on an AP.
<u>usb-profile</u>	Shows the AP USB profile.
<u>vht-rates</u>	Shows Very-High-Throughput (VHT) rates for an AP that supports 802.11ac.
<u>virtual-beacon-report</u>	Shows the virtual beacon report for an AP or a client with a specific IP or MAC address.
<u>vlan-mcast</u>	Shows user count in each VLAN and timestamps for tunnel to join or leave VLAN-Multicast group.
<u>vlan-usage</u>	Shows the numbers of clients on each VLAN.
<u>wifi-uplink blacklist</u>	Shows a list of Wi-Fi uplink APs that have been denied access.
<u>wifi-uplink candidates</u>	Shows a list of Wi-Fi uplink candidate APs.
<u>wifi-uplink connection-history</u>	Shows the connection history of APs with Wi-Fi uplink.
<u>wifi-uplink connection-trace</u>	Shows the connection trace of APs with Wi-Fi uplink.
<u>wifi-uplink current-profile</u>	Shows the current profile information of APs with Wi-Fi uplink.
<u>wifi-uplink debug</u>	Shows debug information of APs with Wi-Fi uplink.

Parameter	Description
wifi-uplink neighbors	Shows information of neighboring APs by scanning them.
wifi-uplink provisioned-profiles	Shows information of provisioned profiles of APs with Wi-Fi uplink.
wifi-uplink status	Shows the status of APs with Wi-Fi uplink.
wifi-uplink stats	Shows the statistics of APs with Wi-Fi uplink.
wifi-uplink-profile	Shows a list of all Wi-Fi uplink profiles, or display the configuration parameters in a specific Wi-Fi uplink profile.
wired stats	Shows statistics for campus and remote AP wired clients.
wired-ap-profile	Shows a list of all wired AP profiles, or display the configuration parameters in a specific wired AP profile.
wired-port-profile	Shows all AP wired port profiles and their status.
wmm-flow	Shows the Wireless Multimedia (WMM) flow table.
zigbee-client-database	Shows all Zigbee client information of APs.

Command History

Release	Modification
ArubaOS 8.9.0.0	All instances of <code>blacklist</code> have been replaced with <code>denylist</code> .
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms.	Base operating system.	Config or Enable mode on Mobility Conductor.

show ap active

```
show ap active
  2.4GHz

  type
  voip-only
```

Description

This command shows Access Points registered to a Mobility Conductor. Click parameter links to view the corresponding show commands.

Parameter	Description
2.4GHz	Show 802.11g/2.4 GHz radio information.
5GHz	Show 802.11a/5 GHz radio information.
6GHz (For ArubaOS 8.9.0.0 or later versions)	Show 6 GHz radio information.
ap-name	Shows data for a specified AP name.
arm-edge	Shows the state of ARM edge Access Points.
counters	Shows counters.
details	Shows AP detailed columns.
ssid	Shows data for specified ESSID.
ip-addr	Shows data of an AP for specified IP address.
ip6-addr	Shows data of an AP for specified IPv6 address.
type	Shows information filtered by type of AP.
voip-only	Shows information filtered by associated/active VoIP clients.

Example

The following example shows access points registered to a Mobility Conductor:

```
(host) [mynode] #show ap active

Active AP Table
-----
Name      Group      IP Address      AP Type  Flags  Uptime      Outer IP
Cluster  Role
-----  -

D = Disconn. Extra Calls On; E = Wired AP enabled; F = AP failed 802.1x
authentication;
H = Hotspot Enabled; K = 802.11K Enabled; L = Client Balancing Enabled; M =
Mesh;
N = 802.11b protection disabled; P = PPPOE; R = Remote AP;
S = AP connected as standby; X = Maintenance Mode;
a = Reduce ARP packets in the air; d = Drop Mcast/Bcast On; u = Custom-Cert
RAP;
i = Provisioned as Indoor; o = Provisioned as Outdoor;
p = Restriction mode in POE-AF/AT;r = 802.11r Enabled; f = No Spectrum FFT
support;
Q = DFS CAC timer running; T = Flex Radio Mode is 2.4GHz+5GHz; t = Tri-Radio
Mode Enabled;
U = Flex Radio Mode is 5GHz; V = Flex Radio Mode is 2.4GHz; e = custom EST
cert; W = Dual 5GHz Mode Enabled; 4 = Using WiFi Uplink
Channel followed by "*" indicates channel selected due to unsupported
configured channel.
"Spectrum" followed by "^" indicates Local Spectrum Override in effect.
Channel flags: +/- = 40 MHz, E = 80 MHz, S = 160 MHz, E+E = 80 + 80 MHz
(i.e. 36E+149E)
Cluster Role: U = UAC, A = AAC, SU = Standby UAC , SA = Standby AAC
Num APs:2
```

In releases prior to ArubaOS 8.3.0.0, the output of this command included 2.4 GHz and 5 GHz as output parameters. In ArubaOS 8.3.0.0, these output parameters are modified to display the radio IDs, bands, EIRP, Maximum EIRP, and number of clients.

The output of this command includes the following information:

Column	Description
Name	Name of an AP
Group	The AP is associated with this AP group.
IP address	IP address of the AP, in dotted decimal format.
AP Type	AP model type.
Flags	<p>This column displays any flags for this AP. The list of flag abbreviations is also included in the output of the <code>show ap active</code> command.</p> <ul style="list-style-type: none">■ 1 = 802.1X authenticated AP■ 2 = Using IKE version 2;■ 4 = Using Wi-Fi Uplink■ A = Enet1 in active/standby mode■ B = Battery Boost On■ C = Cellular;■ D = Disconn. Release	Modification
ArubaOS 8.7.0.0	The output parameters <code>Radio 0 Band</code> , <code>Ch/EIRP/MaxEIRP/Clients</code> , <code>Radio 1 Band</code> , <code>Ch/EIRP/MaxEIRP/Clients</code> , and <code>Radio 2 Band</code> , <code>Ch/EIRP/MaxEIRP/Clients</code> will include the following details: <ul style="list-style-type: none"> ■ MPP: Indicates mesh enabled radio of a mesh portal. ■ MPC: The mesh point radio that has a parent link. ■ MPA: The mesh point radio without a parent link.
ArubaOS 8.6.0.0	Two new output parameters <code>Radio 2 Band</code> , <code>Ch/EIRP/MaxEIRP/Clients</code> and flag <code>t</code> were introduced.
ArubaOS 8.5.0.0	A new flag, 4 was introduced to indicate Wi-Fi uplink.
ArubaOS 8.3.0.0	New flags, T , U , V , and W were introduced. In addition, the output parameters for this command were modified to show the radio ID (that is, Radio 0 and Radio 1), radio band, and the debug details such as APs' operation mode for the dual 5GHz mode settings.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode

```
show ap active counters
 2GHz
 5GHz
 ap-name
 arm-edge
 essid
 ip-addr
 ip6-addr
 type
```

Description

This command shows the counters.

Parameter	Description
2GHz	Shows 802.11g radio information.
5GHz	Shows 802.11a radio information.
ap-name	Shows AP information filtered by its name.
arm-edge	Shows the state of ARM edge Access Points.
ssid	Shows data for specified ESSID.
ip-addr	Shows data of an AP for specified IP address.
ip6-addr	Shows data of an AP for specified IPv6 address.
type	Shows information filtered by type of AP.

Example

The following example shows counters:

```
(host)[mynode] #show ap active counters ap-name AP_205
Active AP Table Counters:
Num APs:0
```

Command History

Release	Modification
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

In releases prior to ArubaOS 8.3.0.0, the output of this command included 2.4 GHz and 5 GHz as output parameters. In ArubaOS 8.3.0.0, these output parameters are modified to display the radio IDs, bands, EIRP, Maximum EIRP, and number of clients.

The output of this command includes the following information:

Column	Description
Name	Name of an AP
Group	The AP is associated with this AP group.
IP address	IP address of the AP, in dotted decimal format.
AP Type	AP model type.
Flags	<p>This column displays any flags for this AP. The list of flag abbreviations is also included in the output of the <code>show ap active</code> command.</p> <ul style="list-style-type: none">■ 1 = 802.1X authenticated AP■ 2 = Using IKE version 2;■ 4 = Using Wi-Fi Uplink■ A = Enet1 in active/standby mode■ B = Battery Boost On■ C = Cellular;■ D = Disconn. Extra Calls On■ E = Wired AP enabled■ F = AP failed 802.1X authentication■ H = Hotspot Enabled■ K = 802.11K Enabled■ L = Client Balancing Enabled■ M = Mesh■ N = 802.11b protection disabled■ P = PPPOE■ R = Remote AP■ S = AP connected as standby■ X = Maintenance Mode■ a = Reduce ARP packets in the air■ d = Drop Mcast/Bcast On■ u = Custom-Cert RAP■ i = Provisioned as indoor■ o = Provisioned as outdoor■ p = Restriction mode in POE-AF/AT■ r = 802.11r Enabled■ t=Tri-radio mode enabled■ Q = DFS CAC timer running■ T = Flex Radio Mode is 2.4GHz+5GHz■ U = Flex Radio Mode is 5GHz■ V = Flex Radio Mode is 2.4GHz■ W = Dual 5 GHz Mode Enabled

Column	Description
Uptime	Number of hours, minutes and seconds since the last Mobility Conductor reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .
Outer IP	The outer IP address of a Remote AP is used to establish an IPsec VPN tunnel to the terminating Mobility Conductor. The RAP acquires an outer IP address from the locally connected network, usually via DHCP. (A Remote AP is typically behind a NAT device whose public IP is seen as the outer IP for the Remote AP).
Radio 0 Band Ch/EIRP/MaxEIRP/Clients	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 0.
Radio 1 Band Ch/EIRP/MaxEIRP/Clients	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 1.
Radio 2 Band Ch/EIRP/MaxEIRP/Clients	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 2.

ArubaOS 8.6.0.0	Two new output parameters <code>Radio 2 Band Ch/EIRP/MaxEIRP/Clients</code> and <code>flag t</code> were introduced.
ArubaOS 8.5.0.0	A new flag, 4 was introduced to indicate Wi-Fi uplink.
ArubaOS 8.3.0.0	New flags, T , U , V , and W were introduced. In addition, the output parameters for this command were modified to show the radio ID (that is, Radio 0 and Radio 1), radio band, and the debug details such as APs' operation mode for the dual 5GHz mode settings.
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Config or Enable mode on Mobility Conductor.

In releases prior to ArubaOS 8.3.0.0, the output of this command included 2.4 GHz and 5 GHz as output parameters. In ArubaOS 8.3.0.0, these output parameters are modified to display the radio IDs, bands, EIRP, Maximum EIRP, and number of clients.

The output of this command includes the following information:

Column	Description
Name	Name of an AP
Group	The AP is associated with this AP group.
IP address	IP address of the AP, in dotted decimal format.
AP Type	AP model type.
Flags	<p>This column displays any flags for this AP. The list of flag abbreviations is also included in the output of the <code>show ap active</code> command.</p> <ul style="list-style-type: none">■ 1 = 802.1X authenticated AP■ 2 = Using IKE version 2;■ 4 = Using Wi-Fi Uplink■ A = Enet1 in active/standby mode■ B = Battery Boost On■ C = Cellular;■ D = Disconn. Extra Calls On■ E = Wired AP enabled■ F = AP failed 802.1X authentication■ H = Hotspot Enabled■ K = 802.11K Enabled■ L = Client Balancing Enabled■ M = Mesh■ N = 802.11b protection disabled■ P = PPPOE■ R = Remote AP■ S = AP connected as standby■ X = Maintenance Mode■ a = Reduce ARP packets in the air■ d = Drop Mcast/Bcast On■ u = Custom-Cert RAP■ i = Provisioned as indoor■ o = Provisioned as outdoor■ p = Restriction mode in POE-AF/AT■ r = 802.11r Enabled■ t=Tri-radio mode enabled■ Q = DFS CAC timer running■ T = Flex Radio Mode is 2.4GHz+5GHz■ U = Flex Radio Mode is 5GHz■ V = Flex Radio Mode is 2.4GHz■ W = Dual 5 GHz Mode Enabled

Column	Description
Uptime	Number of hours, minutes and seconds since the last Mobility Conductor reboot or bootstrap, in the format <i>hours:minutes:seconds</i> .
Outer IP	The outer IP address of a Remote AP is used to establish an IPsec VPN tunnel to the terminating Mobility Conductor. The RAP acquires an outer IP address from the locally connected network, usually via DHCP. (A Remote AP is typically behind a NAT device whose public IP is seen as the outer IP for the Remote AP).
Radio 0 Band Ch/EIRP/MaxEIRP/Clients	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 0.
Radio 1 Band Ch/EIRP/MaxEIRP/Clients	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 1.
Radio 2 Band Ch/EIRP/MaxEIRP/Clients	Radio ID, channel, EIRP, Maximum EIRP, and the number of clients using Radio 2.

show ap-group

```
show ap-group [default|NoAuthApGroup|<profile-name>]
```

Description

This command shows configuration for an AP group. Run this command without the optional parameters to display the entire AP group list, including profile status for each profile. Include an AP group name to display detailed configuration for that AP group.

Parameter	Description
default	Shows setting for default AP group.
NoAuthApGroup	Shows setting for NoAuthAP group.
<profile-name>	Shows setting for specified AP group.

Examples

The following example shows the AP group list:

```
(host) [mynode] #show ap-group

AP group List
-----
Name           Profile Status
----           -
default
NoAuthApGroup  Predefined (changed)

Total:2
```

The following example shows the configuration of an AP group named **default**:

```
(host) [mynode] #show ap-group default

AP group "default"
-----
Parameter                               Value      Set
-----
Virtual AP                               N/A
802.11a radio profile                    default
802.11g radio profile                    default
802.11 6GHz radio profile                default
802.11 60GHz radio profile               default
Ethernet interface 0 port configuration  default
Ethernet interface 1 port configuration  default
```

```

Ethernet interface 2 port configuration shutdown
Ethernet interface 3 port configuration shutdown
Ethernet interface 4 port configuration shutdown
Ethernet usb port configuration shutdown
AP system profile default
AP multizone profile default
802.11a Traffic Management profile N/A
802.11g Traffic Management profile N/A
Regulatory Domain profile default
RF Optimization profile default
RF Event Thresholds profile default
IDS profile default
Mesh Radio profile default
Mesh Cluster profile N/A
AM filter profile default
Provisioning profile N/A
AP authorization profile N/A
Mesh Accesslist profile ACL
Airslice profile Airslice profile 1

```

The output of this command includes the following parameters:

Parameter	Description
Virtual AP	Virtual AP profile that which configures a specified WLAN.
802.11a radio profile	Profile that defines 802.11a radio settings for the AP group.
802.11g radio profile	Profile that defines 802.11g radio settings for the AP group.
802.11 6GHz radio profile	Profile that defines 802.11 6 GHz radio settings for the AP group.
802.11 60GHz radio profile	Profile that defines 802.11 60 GHz radio settings for the AP group.
Wired AP profile	Profile that defines wired port settings for APs assigned to the AP group.
Ethernet interface 0 link profile	Profile that defines the duplex and speed of the Ethernet 0 interface on the AP.
Ethernet interface 1 link profile	Profile that defines the duplex and speed of the Ethernet 0 interface on the AP.
AP system profile	Name of the AP system profile for the AP group.
802.11a Traffic Management profile	Name of the 802.11a WLAN traffic management profile for the AP group.

Parameter	Description
802.11g Traffic Management profile	Name of the 802.11g WLAN traffic management profile for the AP group.
Regulatory Domain profile	Name of the regulatory domain profile for the AP group.
SNMP profile	Name of the SNMP profile for the AP group.
RF Optimization profile	Name of the RF optimization profile for the AP group.
RF Event Thresholds profile	Name of the RF event thresholds profile for the AP group.
IDS profile	IDS profile for the AP group.
Mesh Radio profile	Mesh radio profile assigned to the AP group.
Mesh Cluster profile	Mesh cluster profile assigned to the AP group.
Mesh Accesslist Profile	Mesh access list profile assigned to the AP.
AirSlice Profile	Air Slice profile assigned to the AP.

Ethernet interface 4 port configuration   shutdown
AP system profile                         default
AP multizone profile                      default
802.11a Traffic Management profile        N/A
```

802.11g Traffic Management profile	N/A
Regulatory Domain profile	default
RF Optimization profile	default
RF Event Thresholds profile	default
IDS profile	default
Mesh Radio profile	default
Mesh Cluster profile	N/A
AM filter profile	default
Provisioning profile	N/A
AP authorization profile	N/A
Mesh Accesslist profile	ACL
Airslice profile	Airslice profile 1

The output of this command includes the following parameters:

Column	Description
Virtual AP	Virtual AP profile that which configures a specified WLAN.
Excluded Virtual AP	Excludes the specified mesh cluster profile from this AP.
802.11a radio profile	Profile that defines 802.11a radio settings for the AP.
802.11g radio profile	Profile that defines 802.11g radio settings for the AP.
Wired AP profile	Profile that defines wired port settings for APs assigned to the AP.
Ethernet interface 0 link profile	Profile that defines the duplex and speed of the Ethernet 0 interface on the AP.
Ethernet interface 1 link profile	Profile that defines the duplex and speed of the Ethernet 0 interface on the AP.
AP system profile	Name of the AP system profile for the AP.
802.11a Traffic Management profile	Name of the 802.11a WLAN traffic management profile for the AP group.
802.11g Traffic Management profile	Name of the 802.11g WLAN traffic management profile for the AP.
Regulatory Domain profile	Name of the regulatory domain profile for the AP.
RF Optimization profile	Name of the RF optimization profile for the AP.
RF Event Thresholds profile	Name of the RF event thresholds profile for the AP.
IDS profile	IDS profile for the AP.

Column	Description
Mesh Radio profile	Mesh radio profile assigned to the AP.
Mesh Cluster profile	Mesh cluster profile assigned to the AP.
Excluded Mesh Cluster profile	Excludes the specified mesh cluster profile from this AP.
Mesh Accesslist Profile	Mesh access list profile assigned to the AP.
AirSlice Profile	Air Slice profile assigned to the AP.

show ap allowed-channels

```
show ap allowed-channels
  ap-name <ap-name>
  country-code <country-code> [ap-type <ap-type>]
  ip-addr <ip-addr>
```

Description

This command shows the allowed channels on a specific AP name, country code, or IP address. Specify the country code for your controller during initial setup. Changing the country code causes the valid channel lists to be reset to the defaults for that country.

Parameter	Description
ap-name <ap-name>	Specifies name of an AP.
country-code <country-code> [ap-type <ap-type>]	Specifies country code. If you specify the optional ap-type <ap-type> parameter, the output shows allowed channels for the specified AP type in that country code. The <ap-type> parameter is the two or three digit model number of the AP, such as 135 for AP-135 or 225 for AP-225. For remote APs, like RAP-3WN, specify the prefix RAP- before the AP model number. If the AP model number includes an alphabetic suffix, such as the AP-175AC, specify the suffix after the model number. Note that the suffix may be case-sensitive.
<ip-addr>	Specifies the IP address of an AP.

Examples

The following example shows all allowed channels for the country code **US**.

- For versions prior to ArubaOS 8.9.0.0:

```
(host) [mynode]# show ap allowed-channels US

Allowed Channels for Country Code "US" Country "United States"

show ap allowed-max-eirp

```
show ap allowed-max-EIRP {ap-name <ap-name>}|{ip-addr <ip-addr>}
```

Description

The output of this command shows the regulatory power limits per channel for a specified AP. The values showed in the output of this command include the antenna gain for that device, regardless of whether the AP antenna is internal or external. MIMO gain (if applicable) is also accounted for in the maximum EIRP limits.

Parameter	Description
ap-name <ap-name>	Shows the maximum EIRP setting per country per AP type for specified AP name.
ip-addr <ip-addr>	Shows the maximum EIRP setting per country per AP type for specified IP address.

Examples

The output of this example shows the allowed per-channel EIRP maximums for an AP-325. In the following example, the output is divided into two parts to better fit on the pages of this document. In the ArubaOS CLI, the output appears in a single, long table.

```
(host)# show ap allowed-max-eirp ap-name local-ap-325

Max EIRP setting for AP-325

ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable mode on Mobility Conductor.

show ap am-filter-profile

```
show ap am-filter-profile
  default
  <profile-name>
```

Description

This command shows the AM filter for an AP.

Parameter	Description
<profile-name>	Shows AM filter for specified profile name.

Example

The following example shows the AM filter for an AP:

```
(host) [mynode] #show ap am-filter-profile

AM Filter List
-----
Name      References  Profile Status
----      -
default  2

Total:1
The following example shows the AM filter for a default AP:
(host) [mynode] #show ap am-filter-profile default

AM Filter "default"
-----
Parameter                Value      Set
-----                -
Filtering                 Disabled
Allow AP's Group         Disabled
Allow Frames from Self   Disabled
Allowed AP Group         N/A
Allowed AP                N/A
```

show ap analytics recommendations

ap-setting
pending-ap
radio-setting
stats

Description

This command shows the recommendations received from an analytics engine. This information includes the EIRP recommendations, channel-bandwidth recommendations, and regulatory domain profile recommendations to an AP. Click parameter links to view the corresponding show commands.

Parameter	Description
ap-setting	Displays the recommendations for AP level settings.
pending-ap	Displays the pending AP list.
radio-setting	Displays the recommendations for an active AP.
stats	Displays the statistics for recommendations received by the analytics engine.

Command History

Release	Modification

show ap analytics recommendations ap-setting

```
database <all|ap-name|inactive|invalid|ip-addr|ip6-addr|valid|wired-mac>  
running <all|ap-name|ip-addr|ip6-addr|wired-mac>
```

Description

This command shows the recommendations for AP level settings.

Parameter	Description
database	Displays the recommendations available in the database.
all	Displays all the recommendations available in the database.
ap-name	Displays the recommendations available for an AP in the database.
inactive	Displays all the recommendation entries for inactive AP(s) in database.
invalid	Displays invalid recommendation entries in database.
ip-addr	Displays the recommendations available for an IP address of the AP .
ip6-addr	Displays the recommendations available for an IPv6 address of the AP.
valid	Displays valid recommendation entries in database.
wired-mac	Displays the recommendations available for a MAC address of the AP.
running	Displays all the recommendation entries for active AP(s) in database.
all	Displays all the recommendations available in the database.
ap-name	Displays the recommendations available for an AP in the database.
ip-addr	Displays the recommendations available for an IP address of the AP .
ip6-addr	Displays the recommendations available for an IPv6 address of the AP.
wired-mac	Displays the recommendations available for a MAC address of the AP.

Example

The following example shows the AP analytics recommendations data:

```
(host) [mynode] #show ap analytics recommendations ap-setting database all
AP Recommendations Info
```

```
-----
Wired-MAC AP Name Assign source 2.4GHz 20MHz Channels 2.4GHz 40MHz

ip6-addr	Displays the recommendations available for an IPv6 address of the AP.
wired-mac	Displays the recommendations available for a MAC address of the AP.

```
all
last
```

Description

Displays the statistics for recommendations received by the analytics engine.

Parameter	Description
all	Displays all the statistics recommendation entries.
last	Displays specific count of latest statistics recommendation entries.

Example

The following example shows all the statistics recommendation entries:

```
(host)[mynode] #show ap analytics recommendations stats all
Flags: B - Channel Bandwidth | C - Channel-list | E - EIRP
Analytics Statistics
-----
ID  Timestamp  Rules-Filename  Schema Version Major/Minor/Patch  Analytics
ID  Revoke All/Radio/AP  Total  Processed E/B/C  Total Error E/B/C
--  -----
-  -----
Total count :0
```

Command History

Release	Modification
ArubaOS 8.4.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

```
show ap antenna status
```

```
ap-name <name> radio <0,1,2> advanced
ip-addr <ip-address> radio <0,1,2> advanced
ip6-addr <ipv6-address> radio <0,1,2> advanced
```

Description

This command displays the operational antenna status of APs, and helps in identifying malfunctioning antennas. The status is displayed by comparing the SNR values received on each antenna.

Parameter	Description
ap-name <ap-name>	Name of the access point.
ip-addr <ip-addr>	IP address of the access point.
ip6-addr <ip-addr>	IPv6 address of the access point.
radio	Radio ID (0,1 or 2)
advanced	Use this optional parameter to view additional statistics.

The command displays the following status:

Status	Description
OK	Antenna is fine.
NOT_OK	Antenna is either loose or malfunctioning.
PENDING	The status of the antenna is yet to be determined.

Example

The following example displays the operational antenna status of an APs:

```
(host) [mynode] #show ap antenna-status ap-name SSAP335 radio 1 advanced
Antenna Status
-----
#Chains    Avg Rx SNR  Status
-----
0          0          PENDING
1          0          PENDING
```

```
2          0          PENDING
3          0          PENDING
```

```

Related Commands

Command	Description
show ap provisioning	This command shows the provisioning parameters currently used by an AP.

Command History

Revision	Modification
ArubaOS 8.8.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

show ap ap-cert-mgr

```
show ap ap-cert-mgr
log {ap-name <ap-name>[<page>]|ip-addr <ip-addr>[<page>]}
```

Description

This command displays the contents of the debug log file for an AP. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
log	Show debug log for an AP.
ap-name <ap-name> ip-addr <ip-addr>	Specify name or IP address of the AP .
<page>	Specify page number of the log file.

Example

The following command displays the debug logs for an AP.

```
(host) [mynode] ##show ap ap-cert-mgr log ip-addr 192.168.1.25
```

Related Commands

show ap ap-group

```
show ap ap-group {ap-name <ap-name>|bssid <bssid>|ip-addr <ip-addr>|ip6-addr <ip-addr>|wired-mac <mac-addr>}
```

Description

Shows the AP group settings for an individual AP. Use this command to display the contents of an AP's group profile. If you know the name of the group whose profile settings you want to view, use the command `show ap-group <profile-name>`. To view a list of all configured AP groups on your Mobility Conductor, use the command `show ap-group`.

Parameter	Description
ap-name <ap-name>	Shows data for an AP with a specific name.
bssid <bssid>	Shows data for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Shows data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.
ip6-addr <ip-addr>	Shows data for an AP with a specific IPv6 address.
wired-mac <mac-addr>	Shows data for an AP with a specific MAC address.

Examples

In the example below, the output of this command lists the profiles associated with the AP group **Corp13**.

```
(host) [mynode] #show ap ap-group AP2

AP group "corp13"
-----
Parameter                               Value
-----
Virtual AP                               N/A
802.11a radio profile                     default
802.11g radio profile                     default
Ethernet interface 0 port configuration   default
Ethernet interface 1 port configuration   default
Ethernet interface 2 port configuration   shutdown
Ethernet interface 3 port configuration   shutdown
Ethernet interface 4 port configuration   shutdown
AP system profile                         default
AP multizone profile                       default
802.11a Traffic Management profile         N/A
```

802.11g Traffic Management profile	N/A
Regulatory Domain profile	default
RF Optimization profile	default
RF Event Thresholds profile	default
IDS profile	default
Mesh Radio profile	default
Mesh Cluster profile	N/A
AM filter profile	default
Provisioning profile	N/A
AP authorization profile	N/A

```

Description

This command displays ARM information. Click parameter links to view the corresponding show commands.

Parameter	Description
bandwidth management	Shows bandwidth management information for clients associated to an AP.
client-match debug state	Shows the debug information for internal state of objects.
client-match history	Shows the history of AP association changes triggered by the ClientMatch feature.
client-match mapping	Shows the mapping of radio to envID.
client-match msg-stats	Shows Client Match related message stats.
client-match neighbors	Shows the BSSID of other APs seen by clients in the select AP's RF neighborhood.
client-match pending	Shows the pending moves.
client-match probe-report	Shows the client probe report for the specified AP.

Parameter	Description
client-match radio-summary	Shows the summary of radios in the network.
client-match restriction-table	Shows the list of clients that ClientMatch has restricted from the specified AP.
client-match rules	Shows the rules of AP association changes triggered by the client match feature.
client-match summary	Shows the history of AP association changes triggered by the client match feature.
client-match unsupported	Shows a list of clients that failed to be steered to a more optimal AP, and the reason the initial steering request was triggered.
history	Shows the history of the channel and power changes due to Adaptive Radio Management (ARM).
neighbors	Shows the ARM settings for an AP's neighbors.
rf-summary	Shows the state and statistics for all channels being monitored by an individual AP.
scan-times	Shows channel scan times for an individual AP and information on the channel being scanned.
split-scan-history	Show scanning information for a "split-scan".
state	Shows aggregate ARM neighbor information.
status	Show the status of ARM on AP.
virtual-beacon-report	Shows the virtual beacon report for an AP

show ap arm bandwidth-management

```
show ap arm bandwidth-management ap-name <ap-name> ip-addr <ip-addr>
```

Description

If the client match feature is enabled, the output of this command shows bandwidth management information for clients associated to an AP.

Parameter	Description
ap-name <ap-name>	Name of the access point.
ip-addr <ip-addr>	IP address of the access point.

Example

The following command shows bandwidth management information for clients associated to an AP,

```
(host) [md] #show ap arm bandwidth-management ap-name AP-225
Interface :wifi0
Shaping policy:Default-access (no stats)
Interface :wifi1
Shaping policy:Default-access (no stats)
```

show ap arm client-match debug state

```
show ap arm client-match debug state  
{bssid <bssid>|client-mac <client-mac>|radio-bssid <radio-bssid>}
```

Description

If the Client Match feature is enabled, the output of this command displays the debug information for internal state of objects. The optional output modifiers | begin , | exclude, and | include help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The | redirect-output modifier helps you redirect the command output.

Parameter	Description
bssid <bssid>	The BSSID for VAPs.
client-mac <client-mac>	The MAC address for stations.
radio-bssid <radio-bssid>	The BSSID for radios.

Example

```
(host)#show ap arm client-match debug state bssid 90:4c:81:73:d8:b0  
Mac :90:4c:81:cf:3d:8a  
BSSID :90:4c:81:73:d8:b0

show ap arm virtual-beacon-report	This command displays the virtual beacon report for an AP with a specific IP or MAC address.
show ap arm client-match unsupported	This command displays a list of clients that failed to be steered to a more optimal AP, and the reason the initial steering request was triggered.
show ap arm client-match summary	This command shows the history of AP association changes triggered by the client match feature.
show ap arm client-match restriction-table	This command displays the list of clients that ClientMatch has restricted from the specified AP.

Command History

Command	Description
ArubaOS 8.0.0.0	Command introduced.

Command Information

Platforms	License	Command Mode
All platforms	Base operating system.	Enable or Config mode on Mobility Conductor.

```
show ap arm client-match msg-stats
  radio <radio-bssid>
```

Description

If the Client Match feature is enabled, the output of this command displays Client Match related message stats. The optional output modifiers `| begin`, `| exclude`, and `| include` help you display those lines that begin, include, exclude, respectively, the line expression given in the CLI command. The `| redirect-output` modifier helps you redirect the command output.

Parameter	Description
radio <radio-bssid>	The BSSID of the radio.

Example

```
(host) #show ap arm client-match msg-stats
ARM PAPI in pkt statistics -
ARM update :: 0
Dropped :: 0
Trigger Client Assist :: 0
Client Match Report :: 0
802.11k Action Frame :: 0
802.11v Action Frame :: 0
CM VBR Report :: 0
Client Management Message :: 0
802.11 Management Message :: 0
ARM RBCM Activation Message :: 0
ARM PAPI out pkt statistics -
ARM update :: 0
Dropped :: 0
Trigger Client Assist :: 0
Client Match Report :: 0
802.11k Action Frame :: 0
802.11v Action Frame :: 0
CM VBR Report :: 0
Client Management Message :: 0
802.11 Management Message :: 0
ARM RBCM Activation Message :: 0
```

show ap arm client-match neighbors

```
show ap arm client-match neighbors
  ap-name <name>
  ip-addr <ipaddr>
  ip6-addr <ipaddr>
```

Description

If the client match feature is enabled, the output of this command displays the BSSID of other APs seen by clients in the select AP's RF neighborhood.

Parameter	Description
ap-name <name>	View neighboring clients for an AP with a specified name
ip-addr <ipaddr>	View neighboring clients for an AP with a specified IP address.
ipv6-addr <ipaddr>	View neighboring clients for an AP with a specified IPv6 address.

Example

```
(host) [mynode] #show ap arm client-match neighbors ap-name 345-9C
Client View
-----
AP      BSSID                Channel  Clients
--      -
345-9C  c8:b5:ad:ba:f9:d0    157     1
334-12  18:64:72:7e:e1:30    44      0
345-9C  c8:b5:ad:ba:f9:c0    6       0
```

The output of this command includes the following parameters:

Parameter	Description
BSSID	BSSID of the AP.
Channel	Channel of operation of the AP.
Clients	Total number of clients.

show ap arm client-match probe-report

```
show ap arm client-match probe-report
  ap-name <name>
  ip-addr <ipaddr>
  ip6-addr <ip6-addr>
  assoc
  phy-type 802.11a|802.11b|80211g
```

Description

If ClientMatch is enabled, the output of this command displays the client probe report for the specified AP. APs using ClientMatch maintain a table of clients that have sent probe requests, and the signal-to-noise ratio (SNR) of the frame the AP received from the client. The AP sends these reports to the managed device every 30 seconds and the managed device forwards this information to the Mobility Conductor, which uses the information in these reports to steer each client to its optimal AP.

Parameter	Description
ap-name <name>	Name of the AP for which you want to view a client report.
ip-addr <ip-addr>	IPv4 address of an AP for which you want to view a client probe report.
ip6-addr <ip6-addr>	IPv6 address of an AP for which you want to view a client probe report.
assoc	Show information for associated clients only.
phy-type	Show information for one of the following phy types: <ul style="list-style-type: none">■ 802.11a■ 802.11b■ 80211g

Example

```

```

The output of this command includes the following parameters:

Column	Description
Client MAC	AP name of the AP from which the client can detect a signal.
Signal	Signal strength, in dBm, of the probe request received from the client.
Assoc	A "Y" in this field indicates that the client is currently associated to that AP radio.
Sec since last heard	Time elapsed since the AP radio heard from the client.
Sec since last reported	Time elapsed since the AP radio heard from the client.
Last heard	Date and time at which the AP last heard from the client

show ap arm client-match restriction-table

```
show ap arm client-match restriction-table
  ap-name <name>
  ip-addr <ipaddr>
  ip6-addr <ip6-addr>
```

Description

If ClientMatch is enabled, the output of this command displays the list of clients that ClientMatch has restricted from the specified AP. These lists of restricted clients help the client associate to the best AP, by preventing the client from associating with a sub-optimal AP radio. The output of this command shows a list of all clients that were ever blacklisted from the specified AP.

Parameter	Description
ap-name <name>	Name of the AP for which you want to view the list of restricted clients
ip-addr <ipaddr>	IPv4 address of the AP for which you want to view the list of restricted clients
ip6-addr <ip6addr>	IPv6 address of the AP for which you want to view the list of restricted clients

Example

```
(host)[node] #show ap arm client-match restriction-table ap-name <ap-name>

Client Restriction Table for Wifi0
-----
Client MAC           Time last restricted   Restricted(Cur/Last)

-----
3866                             00:1a:1e:89:c0:c0

```

The output of this command includes the following parameters:

Column	Description
Client MAC	Displays the MAC address of the client that Client Match is attempting to steer.
Time last restricted	Displays the date and time at which the client was last steered in the vicinity of this radio.
Restricted(Cur/Last)	A "1" in this field indicates that the client is currently in the process of being steered to another radio.
PS deauth	Displays if the client is in power save mode when client match is attempting to steer the client.
Probe(home/scan/bc_ssid)	Displays the number of probe requests received on home channel, AP scanning, and SSID broadcast probe.
Auth(home/scan)	Displays the number of probe requests received on home channel and AP scanning for 802.11 authentication frames.
Time since last restricted	Display the time (in seconds) since the client was last steered in the vicinity of this radio.
Radio Bssid	Displays the unique hard-wireless MAC address of the AP. A unique BSSID applies to each frequency— 802.11a and 802.11g—used from the AP.

All platforms	base operating system.	Enable or Config mode on Mobility Conductor.

show ap arm client-match unsupported

show ap arm client-match unsupported

Description

If the client match feature is enabled, the output of this command displays a list of clients that failed to be steered to a more optimal AP, and the reason the initial steering request was triggered. The controller also keeps track of the number of times the client match feature failed to steer a client to a different radio, and the reason that each steer attempt was triggered. If the client match feature attempts to steer a client to a new radio multiple consecutive times for the same reason but client steering fails each time, the controller notifies the AP to mark the client as un-steerable for that specific trigger.

Example

The following example displays a list of unsteerable clients. (For versions prior to ArubaOS 8.10.0.0.)

```
(host) [mynode] (config) #show ap arm client-match unsupported

Client Match Unsteerable Clients
-----
MAC  Unsteerable Flags  Last Steer Time  Expiry Time  Total
steers/successful
---  -----

S: Sticky L: Load Balance H: HE Steer B5G: Bandsteer to 5GHz B6G: Bandsteer
to 6GHz I: IOS T: Temporary D(I): dot11v IOS Mr: MU steer (R): Rule based
Vo: Voice Roam P: HE-Pooling
```

```
Total Unsteerable Clients:0
```

The output of this command includes the following parameters:

Column	Description
MAC	MAC address of the client that could not be steered to a different AP radio.
Unsteerable Flags	<p>The client is marked unsteerable under specific client steer triggers. These triggers include:</p> <ul style="list-style-type: none">■ Sticky: A mobile roaming client is staying associated (sticking) to a sub-optimal AP for too long.■ Bandsteer: A dual-band capable client is steered towards a 5 GHz radio on a dual-band AP. (For versions prior to ArubaOS 8.10.0.0.)■ Bandsteer to 5GHz: A dual-band capable client is steered towards a 5 GHz radio on a dual-band Wi-Fi 6E AP. (For ArubaOS 8.10.0.0 or later versions.)■ Bandsteer to 6GHz: A dual-band capable client is steered towards a 6 GHz radio on a dual-band Wi-Fi 6E AP. (For ArubaOS 8.10.0.0 or later versions.)■ Load Balance: Client match moved the client to a different AP, based upon the load on APs in the client's RF neighborhood, and the SNR levels the client detected from each underutilized AP.■ IOS: An IOS device is temporarily prevented from steering to avoid blacklisting/denylisting the ESS.■ Temporary: A client is temporarily prevented from steering after undergoing a successful band steer, then reverting back to a 2.4GHz radio.■ HE Steer: HE Steer will not be attempted for the client.■ MU Steer: MU Steer will not be attempted for the client■ Dot 11v IOS: IOS client has been marked unsteerable for steers.■ Rule based: Client has been marked unsteerable by Rules Based Client Match (RBCM).■ Voice Roam: Voice roam steer will not be attempted for the client.
Last Steer Time	Timestamp showing the date and time the client match feature failed to associate the client to a different AP radio.
Expiry Time	The amount of time before a client steer attempt expires.
Total steers/successful	The total number of client steer attempts, and the number of successful client steer attempts.

show ap arm history

```
show ap arm history {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

Description

For each interface on an AP, this command shows the history of the channel and power changes due to Adaptive Radio Management (ARM).

Parameter	Description
ap-name <ap-name>	Show ARM history for an AP with a specific name.
bssid <bssid>	Show ARM history for a specific Basic Service Set Identifier (BSSID) on an AP. An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show ARM history for an AP with a specific IP address. Enter the IP address in dotted-decimal format.

Example

Adaptive Radio Management (ARM) can automatically change channel and power levels based on a number of factors such as noise levels and radio interference.

The following example shows an AP's channel and power changes over time, and the reason why those changes took place (For versions prior to ArubaOS 8.9.0.0).

```
(host)[node]#show ap arm history ap-name AP-16
Interface :wifi0

Channel, RMC: Radio Mode Change, RCP: Radio Client Preference Change,
OFF(C) : Turn off Radio due to config

```

The output of this command includes the following information:

Column	Description
Phy-Type (ArubaOS 8.9.0.0 or later versions)	The PHY type of the radio. Possible values are 2.4GHz , 5GHz , or 6GHz .
Reason	This column displays one of the following code to indicate why the channel or power change was made. <ul style="list-style-type: none"> ■ I: Interference ■ R: Radar detected ■ N: Noise exceeded ■ E: Error threshold exceeded ■ INV: Invalid Channel ■ G: Rogue AP Containment ■ M: Empty Channel ■ P+: Increase Power ■ P-: Decrease Power ■ OFF: Turn off Radio ■ ON: Turn on Radio

Column	Description
	The Reason key appears at the bottom of the ARM History table.
Old Channel	Channel number used by the AP interface before the ARM change.
New Channel	Channel number used by the AP interface after the ARM change.
Old Power	Power level of the AP interface before the ARM change.
New Power	Power level of the AP interface after the ARM change.
Last Change	Time elapsed since the change, in the format <i>days:hours:minutes:seconds</i> .

show ap arm neighbors

```
show ap arm neighbors {ap-name <ap-name>}|{bssid <bssid>}|{ip-addr <ip-addr>}
```

Description

Show the ARM settings for an AP's neighbors.

Parameter	Description
ap-name <ap-name>	Show data for an AP with a specific name.
bssid <bssid>	Show data for a specific Basic Service Set Identifier (BSSID). An AP's BSSID is usually the AP's MAC address.
ip-addr <ip-addr>	Show data for an AP with a specific IP address. Enter the IP address in dotted-decimal format.

Examples

The following example shows ARM neighbor information for AP name **ap70_1**(For versions prior to ArubaOS 8.9.0.0).

```
(host)[node]# show ap arm neighbors ap-name ap70_1

BSSID: BSSID of discovered radio
ESSID: ESSID of discovered radio/Src BSSID through which the neighbor is
discovered
Channel: Channel of operation of discovered radio
